Esophageal foreign body ingestion in adults on weekdays and holidays

A retrospective study of 1058 patients

Abstract

The purpose of this study is to compare the clinicopathological characteristics and outcomes of esophageal foreign body (FB) ingestion in adults between weekdays and holidays. This is a retrospective study including 1058 patients with esophageal FB ingestion from 2012 to 2016. Patient characteristics, the types and locations of FB, and clinical outcomes were compared between patients on weekdays and holidays. Furthermore, independent risk factors of complication on weekdays and holidays respectively were evaluated. The locations of FB, underlying diseases, and complications significantly differed between weekdays and holidays groups, while no difference was found in the types of FB. Patients got higher percentage of erosion complication on holidays than that on weekdays (60.8% vs 47.6%, P<.0001). Multivariate logistic regression analysis revealed that jujube shell was a significant predictor of complication on weekdays (P<.001). However, complication was significantly associated with nonfood bolus FB ingestion on holidays (P<.001). Our data suggest that there were different clinicopathological characteristics of FB ingestion between weekdays and holidays, and more patients got complications on holidays. On holidays, a latex protector hood or an overtube should be applied to patients who swallowed nonfood bolus in order to reduce esophageal mucosal damage.

Abbreviations: FB = foreign body, GI = gastrointestinal, Post-E resection = postesophageal resection.

Keywords: complication, esophageal, foreign body, holidays, weekdays

1. Introduction

As a common clinical problem, foreign body ingestion sometimes presents as endoscopic emergencies,[1] although the majority of ingested foreign bodies pass spontaneously without complications.[2–4] Actually, esophageal foreign body ingestion has a wide spectrum of clinical manifestations from minor disease that can resolve spontaneously to severe fatal diseases. About 10% to 20% of patients’ foreign body ingestion will require nonoperative intervention, and less than 1% of patients will require a surgical procedure.[5] Most foreign body ingestion occurs without identifiable contributing factors in adults, but some may be due to psychiatric disorders, mental retardation, alcohol consumption, or an edentulous state.[6] Intentionally ingested foreign body commonly require endoscopic treatment (63–76%) and surgery (12–16%).[7,8] An estimated 1500 people in the United States die annually from foreign bodies in the upper gastrointestinal (GI) tract.[9] Crucially, esophageal foreign bodies should be removed within 24 hours because delayed treatment decreases the likelihood of successful removal and increases the risk of complications including risk of perforation.[10,11] Since the first report in 1972 describing the removal of foreign body with a flexible endoscope by McKechnie,[12] esophagogastroduodenoscopy has been a widespread and rapidly developed therapeutic technique, which has recently become the first therapeutic modality for the esophageal foreign body ingestion.[13] Simple radiology would be used before esophagogastroduodenoscopy in most institutions, as it allows the examination of both the pharynx and upper esophagus in patients complaining with only a “neck” foreign body sensation.[14] Most of foreign bodies in adults are caused by the impaction of bone components in food.[15–17] At present, the percentage of bone-type foreign bodies has been shown higher in eastern countries than in western countries.[18] Dietary customs vary depending on the region of origin, culture, and religious beliefs. Eating practices are not only
a part of the habituated lives of people but also linked to cultural identity, which makes food imbued with social and cultural meaning.\textsuperscript{[19,20]} Dietary change has been shown to alter the management of heart failure in older Chinese people.\textsuperscript{[21]} According to Chinese dietary custom, people are happy to enjoy a hearty dinner during holidays, which may affect the occurrence of esophageal foreign body, but none has ever investigated the influence of dietary change on esophageal foreign body ingestion. In this study, we compared the type and location of foreign bodies and clinical outcomes on weekdays and holidays, and further evaluated the predictors of complication on weekdays and holidays, respectively.

2. Materials and methods

2.1. Study population selection

A retrospective study was conducted on adult patients with suspected foreign body ingestion in the esophagus who visited the emergency department or outpatient clinic or during hospitalization in Nanjing Drum Tower Hospital from January 2012 to January 2016. A total of 1058 patients were enrolled in this study. First, a physical examination would evaluate the patient’s general condition and assess signs of any complications. Second, radiographic study of the neck, chest, and abdomen was taken to assess the presence, location, size, configuration, and number of ingested objects. Computed tomography scan was performed in selected cases in which a complication is suspected. After perforation, peritonitis or small-bowel obstruction were excluded, esophagogastroduodenoscopy would be taken to not only confirm the diagnosis but also rule out foreign body ingestion. A flow diagram of the strategy for inclusion in this study is shown in Fig. 1, and some typical images were presented in Fig. 2. This study had been approved by ethics committee of The Affiliated Drum Tower Hospital of Nanjing University Medical School. There is no need to obtain informed consent from patients because this is a retrospective study and all data were collected and analyzed anonymously.

2.2. Methods

The following clinical data were collected: demographic data, including gender, age, and date of endoscopy (date was divided into weekdays and holidays depending on the adjustment of statutory holidays in China); type of foreign bodies, including fish bone, other animal bone, jujube shell, food bolus, plastic item, metal item, and denture; location of foreign bodies, including upper esophagus (22 cm away from the upper incisor teeth), mid-esophagus (22–30 cm away from the upper incisor teeth), and lower esophagus (30 cm from the terminal of mid-esophagus to esophagogastric junction), anastomosis (postesophagus resection); underlying diseases, including associated upper GI diseases composed of esophagitis, postesophagus resection, esophageal cancer, esophageal stenosis, hiatal hernias and achalasia, and unassociated upper GI diseases composed of esophageal diverticulum, esophageal varices, and inflammation, polyps or ulcer located on cardia, stomach, and duodenum; and complications after foreign body removal, including erosion, perforation, ulceration, and infection, in which erosion refers to relatively mild mucosal damage with slightly bleeding.
2.3. Statistical analysis

Comparisons of continuous variables were conducted by Student t test. Categorical variables were compared using Pearson χ² test or Fisher exact test. Multivariate logistic regression analyses were used to detect independent risk factors predicting the development of complications on weekdays. P values <.05 were considered statistically significant. Analyses were performed using SPSS software, version 22.0 (SPSS Inc., Chicago, IL).

3. Results

3.1. Characteristics and outcomes of patients on weekdays and holidays

From January 2012 to January 2016, 1058 cases (716 patients on weekdays and 342 patients on holidays) occurred in 721 days including 493 weekdays and 228 holidays. Endoscopic removal was successful in 99.3% (1058/1065) of the patients, and the remaining 0.7% (7/1065) required surgery. Among the 7 patients, 3 patients were found on weekdays and 4 patients were found on holidays. The mean age was 52.9 ± 16.5 years for patients on weekdays, and 52.2 ± 16.6 years for patients on holidays. On both weekdays and holidays, the percentage of females was higher than that of males (54.1% vs 45.9% and 56.1% vs 43.9%, respectively), but age and gender distribution were not significantly different between weekdays and holidays (age: χ² = .553; gender: χ² = .520). Fish bones (51.3% on weekdays and 47.1% on holidays) and other animal bones (25.8% on weekdays and 29.2% on holidays) were the most common foreign body, and the proportion of jujube shell (11.7% on weekdays and 13.5% on holidays) and food bolus (8.2% on weekdays and 7.9% on holidays) ingestion is relatively low on weekdays and holidays. The types of foreign body were similarly distributed between weekdays and holidays groups (P = .717). The locations of foreign body ingestion found in esophagus were significantly different between weekdays and holidays groups (P = .024). Foreign bodies located at anastomosis were significantly more common on weekdays (7.0%) than holidays (2.9%) (P < .01), but the location of upper esophagus was more common on holidays (72.5%) than weekdays (65.2%) (P < .05) (Table 1). One hundred nineteen patients had associated upper GI diseases, including esophagitis, postesophagus resection, esophageal cancer, esophageal stricture, and so on. More patients had associated upper GI diseases on weekdays (12.8%) than holidays (7.9%) (P < .05), especially postesophagus resection (weekdays vs holidays: 7.0% vs 2.9%) (P < .01) (Table 1). Four hundred forty patients had none complications with the management of endoscopy. As the most common complication, erosion was noted in 549 cases and significantly more common on holidays (60.8%) than weekdays (47.6%) (P < .001). Distribution of the proportion of serious complications, including perforation, ulceration, and infection, was similar in the 2 groups (Table 1).

3.2. Risk factors predicting the development of complication

Age was not the risk factor for complications on weekdays, as well as on holidays. Type was the only risk factor related with complications of esophageal foreign body ingestion on holidays. Type and location of foreign body and associated upper GI disease were all related with complication with ingestion of foreign body on weekdays. However, type was the only significant risk factor of complications by multivariate logistic regression analyses on weekdays (P < .001). Patients with food bolus ingestion were less likely to get complications both on weekdays (11.9% vs 88.1%, P < .001) and holidays (18.5% vs 81.5%, P < .001). However, patients with jujube shell ingestion were likelier to get complications on weekdays (70.2% vs 29.8%, P < .01) (Tables 2 and 3). A total of 130 patients were found with esophageal jujube shell impaction. Different from nonjujube shell, patients with jujube shell ingestion had more complications, including perforation, ulceration, and infection.

| Parameter                  | Weekdays | Holidays | P     |
|----------------------------|----------|----------|-------|
| Men: women                 | 329/387  | 150/192  | .553 |
| Mean ages, y               | 52.9     | 52.2     | .520 |
| Type of FB                 |          |          | .717 |
| Fish bone (%)              | 367 (51.3) | 161 (47.1) |       |
| Other animal bone (%)      | 185 (25.8) | 100 (29.2) |       |
| Jujube shell (%)           | 84 (11.7)  | 46 (13.5)  |       |
| Food bolus (%)             | 59 (8.2)   | 27 (7.9)   |       |
| Plastic or metal item (%)  | 15 (2.1)   | 5 (1.5)    |       |
| Denture (%)                | 6 (0.8)    | 3 (0.9)    |       |

| Location of FB             |          |          |       |
| Upper esophagus (%)        | 467 (65.2) | 248 (72.5) | .020 |
| Mid-esophagus (%)          | 143 (20.0) | 60 (17.5)  | .360 |
| Lower esophagus (%)        | 56 (7.8)   | 24 (7.0)   | .710 |
| Anastomosis (%)            | 50 (7.0)   | 10 (2.9)   | .007 |
| Associated upper GI diseases |          |          | .017 |
| Esophagitis (%)            | 13 (1.8)   | 5 (1.5)    | .803 |
| Post-E resection (%)       | 50 (7.0)   | 10 (2.9)   | .007 |
| Esophageal cancer (%)      | 18 (2.5)   | 6 (1.8)    | .514 |
| Esophageal stricture (%)   | 5 (0.7)    | 4 (1.2)    | .481 |
| Histaemia (%)              | 3 (0.4)    | 2 (0.6)    | .661 |
| Achalasia (%)              | 3 (0.4)    | 3 (0.9)    |       |
| Complications with FB      |          |          | .001 |
| Erosion (%)                | 341 (47.6) | 208 (60.8) | <.001|
| Perforation (%)            | 26 (3.6)   | 8 (2.3)    | .352 |
| Ulceration (%)             | 12 (1.7)   | 3 (0.9)    | .410 |
| Infection (%)              | 15 (2.1)   | 5 (1.5)    | .631 |
| Total                      | 716       | 342       |       |

FB = foreign bodies, GI = gastrointestinal, OR = odds ratio.

*Student t test, Fisher exact test, and Pearson χ² test were used as appropriate.
shell impaction had higher proportion of female (76.2% vs 51.7%, *P* < .001), older age (38 vs 51.9, *P* < .001), lower proportion of postesophagus resection (1.5% vs 6.3%, *P* < .05), higher proportion of upper esophagus (86.2% vs 64.9%, *P* < .001), and more common complications (72.3% vs 56.5%, *P* < .01) (Table 4). There was a total of 86 patients with ingestion of food bolus and 972 patients with ingestion of nonfood bolus. Patients with ingestion of food bolus had higher proportion of male sex (69.8% vs 43.1%, *P* < .001) and older age (64.9 vs 51.6, *P* < .01) than those with ingestion of nonfood bolus. Postesophagus resection (29.0% vs. 5.4%, *P* < .01) and anastomosis (26.7% vs. 3.8%, *P* < .001) were more common in patients with ingestion of food bolus, but lower proportion of complication was found in these patients (14.0% vs 62.3%, *P* < .01) (Table 5).

FB = foreign body, GI = gastrointestinal.

4. Discussion

Foreign body ingestion is a commonly encountered problem in the esophagendoscopic department around the world. American Society for Gastrointestinal Endoscopy has suggested that only 10% to 20% of foreign bodies may need to be removed endoscopically, but most patients in China were treated endoscopically due to high percentage of bone-type foreign bodies and low cost of endoscopic procedures. The differences of foreign bodies ingested between Chinese and Western populations may result from the difference of dietary customs, but few studies have focused on this factor. On the basis of the difference of eating habits between weekdays and holidays in China, we investigated the characteristics of foreign body ingestion and clinical outcomes between weekdays and holidays. Our study suggested that more patients had associated upper GI diseases on weekdays than those on holidays, especially postesophagus resection. It is noted that patients with food bolus impaction have a significant higher percentage of postesophagus resection than those with other foreign body ingested. This was the potential cause of foreign body impaction, which would pass through the GI tract in healthy people. It is recommended that patients with postesophagus resection chew slowly to avoid the food bolus blocked in the esophagus, especially on weekdays. Foreign bodies located at anastomosis were more common on weekdays than on holidays, but foreign bodies located at upper esophagus were more common on holidays than on weekdays. Sites of trapped foreign bodies may be related to 3 factors: anatomical, pathological, and the nature of foreign body. This, in turn, determined the tools to be used in removal: lodged foreign bodies or food impaction were grasped by forceps while in the stomach, it was easy to use the snare or to open and close the basket.

In our study, we observed that complications of erosion were significantly more common on holidays than on weekdays. It is noted that type of foreign body was the only risk factor related with complications on holidays. Previous study showed that patients with esophageal food bolus impaction had significant fewer complications and higher proportions of esophageal cancer, which is consistent with our result. Patients with impaction of food bolus had lower complications than those with ingestion of nonfood bolus, probably due to that food bolus is different from bone and jujube shell, which have sharp edge. In addition, we found that the type of jujube shell and nonfood bolus was, respectively, committed to complications on weekdays and holidays. In particular, patients with jujube shell ingested were more likely to be female, old, and get
complications. Since the first report in 1972 on the endoscopic removal of a foreign body, flexible endoscopy has been the first choice for esophageal food bolus impaction with high success rate and less complications.[20] Endoscopic removal is characterized by technical facility, excellent visualization, simultaneous diagnosis of other diseases, and a low rate of morbidity.[21] European Society of Gastrointestinal Endoscopy suggests treatment of food bolus impaction in the esophagus by gently pushing the bolus into the stomach. If this procedure is not successful, retrieval should be considered and a repeat endoscopy should be carried out after extraction of foreign bodies in all patients to detect any underlying disease.[22] Nevertheless, in clinical endoscopic practice, if the risk of esophageal perforation and bleeding is high, as in those cases with sharpened or pointed foreign bodies deeply fixed into the wall, it is better to avoid any endoscopic attempts and to resort to surgery.[30]

According to our study, the older women were suggested to change their eating habits or eat non-nuclear jujube. At the same time, a latex protector hood or an overtube especially should be taken for patients with ingestion of nonfood bolus in order to protect the esophageal mucosa during procedure on holidays.

In our center, the endoscopic procedure was performed in most of the patients within 24 hours, because the foreign bodies had not passed through the upper-GI tract. Some studies have shown that long duration from ingestion to endoscopy and mucosal injury were risk factors of complications of endoscopic foreign body removal.[31] On the contrary, Huang et al.[32] have shown that longer wait times are not associated with mucosal injury or postoperative complication. Given the study participants consisted of children, which was different from other researches, more data need to be collected to support this view. However, our investigation was limited by obtaining accurate waiting time from ingestion to endoscopy. Limitations also include the absence of diameter size of ingested foreign body, which was identified as a risk factor predicting conversion to surgery due to inability to remove the foreign body endoscopically.[33] In addition, duration of endoscopic performance may influence treatment outcome, although no study has shown evidence to support this.[34]

5. Conclusion

Our study provides reference for endoscopic treatment of esophageal foreign bodies ingestion between weekdays and holidays. We suggest that patients with postoperative esophagus chew slowly to avoid the food bolus blocked in the esophagus, especially on weekdays. On holidays, a latex protector hood or an overtube should be applied to patients who swallowed nonfood bolus in order to reduce esophageal mucosal damage.
