Algorithmic Thomas Decomposition of Algebraic and Differential Systems

Thomas Bächler, Vladimir Gerdt, Markus Lange-Hegermann, Daniel Robertz

Abstract

In this paper, we consider systems of algebraic and non-linear partial differential equations and inequations. We decompose these systems into so-called simple subsystems and thereby partition the set of solutions. For algebraic systems, simplicity means triangularity, square-freeness and non-vanishing initials. Differential simplicity extends algebraic simplicity with involutivity. We build upon the constructive ideas of J. M. Thomas and develop them into a new algorithm for disjoint decomposition. The given paper is a revised version of Bächler et al. (2010) and includes the proofs of correctness and termination of our decomposition algorithm. In addition, we illustrate the algorithm with further instructive examples and describe its Maple implementation together with an experimental comparison to some other triangular decomposition algorithms.

Keywords: disjoint triangular decomposition, simple systems, polynomial systems, differential systems, involutivity

1. Introduction

Nowadays, triangular decomposition algorithms, which go back to the characteristic set method by Ritt (1950) and Wu (2000), have become powerful tools for investigating and solving systems of multivariate polynomial equations. In many cases these methods are computationally more efficient than those based on construction of Gröbner bases. For an overview over triangular decomposition methods for polynomial and differential-polynomial systems we refer to the tutorial papers by Hubert (2003a, b) and to the bibliographical references therein.

Among numerous triangular decompositions the Thomas one stands by itself. It was suggested by the American mathematician Thomas (1937, 1962) and decomposes a finite system of polynomial equations and/or inequations into finitely many triangular subsystems, which he called simple. The Thomas decomposition splits a given quasi-affine variety into a finite number of quasi-affine varieties defined by simple systems. Unlike other decomposition algorithms, the Thomas decomposition always yields a disjoint decomposition of the solution set.

Wang was the first to design and implement an algorithm that constructs the Thomas decomposition (cf. Wang (1998, 2001); Li and Wang (1999)). For polynomial systems he implemented his algorithm in MAPLE (cf. Wang (2004)) as part of the software package epsilon (cf. Wang (2003)), which also contains implementations of a number of other triangular decomposition algorithms. Dellière (2000) has shown that the “dynamic constructible closure” introduced in the thesis by Gómez Díaz (1994) can be modeled using simple systems. Nonetheless, according to the remark after (Dellière, 2000, Thm. 5.2), simple systems are more general.

Every simple system is a regular system and its equations form a regular chain. The Regular-Chains package (cf. Lemaire et al. (2005)) includes procedures to decompose the solution set of the
input by means of regular chains (if the input only consists of equations) or regular systems. However, the THOMAS decomposition differs noticeably from this decomposition, since the THOMAS decomposition is finer and demands disjointness of the solution set. For a detailed description of algorithms related to regular chains, we refer the reader to Moreno Maza (1999).

The disjointness of the THOMAS decomposition combined with the structural properties of simple systems provide a useful platform for counting solutions of polynomial systems. In fact, the THOMAS decomposition is the only known method to compute the counting polynomial introduced by Plesken (2009a). We refer to §2.3 for details on this structure, counting and their applications.

During his research on triangular decomposition, Thomas was motivated by the Riquier-Janet theory (cf. Riquier (1910); Janet (1929)), extending it to non-linear systems of partial differential equations. For this purpose he developed a theory of (THOMAS) monomials, which generate an involutive monomial division nowadays called THOMAS division (cf. Gerdt and Blinkov (1998a)). He gave a recipe for decomposing a non-linear differential system into algebraically simple and passive subsystems (cf. Thomas (1937)). A modified version of the differential THOMAS decomposition was considered by Gerdt (2008) with its link to the theory of involutive bases (cf. Gerdt and Blinkov (1998a); Gerdt (2005, 1999); Seiler (2010)). In this decomposition, the output systems are JANET-involutive in accordance to the involutivity criterion from Gerdt (2008) and hence they are coherent. For a linear differential system it is a JANET basis of the corresponding differential ideal, as computed by the MAPLE package Janet (cf. Blinkov et al. (2003)).

The differential THOMAS decomposition differs from that computed by the ROSENFELD-GRÖBNER algorithm (cf. Boulier et al. (2009, 1995)). The latter decomposition forms a basis of the difgalg, DifferentialAlgebra and BLAD packages (cf. Boulier and Hubert (1996-2004); Boulier (2004-2009)). Experimentally, we found that these three packages are optimized and well-suited for ordinary differential equations. Furthermore, epsilon also allows to treat ordinary differential systems. Bouziane et al. (2001) mentions another implementation not available to the authors. However, all these methods give a zero decomposition, which, unlike the THOMAS decomposition, is not necessarily disjoint.

In the given paper we present a new algorithmic version of the THOMAS decomposition for polynomial and (ordinary and partial) differential systems. In this unified algorithm, only two changes to the algebraic version are necessary to adapt it for the treatment of differential systems. We briefly describe our implementation of this algorithm in MAPLE.

This paper is organized as follows. In §2, we present the algebraic part of our algorithm for the THOMAS decomposition with its main objects defined in §2.1. In §2.2, we describe the main algorithm and its subalgorithms, followed by the correctness and termination proof. Decomposition of differential systems is considered in §3. Here, we briefly introduce some basic notions and concepts from differential algebra (§3.1) and from the theory of involutive bases specific to JANET division (§3.2). In §3.3, we present our version of the differential pseudo reduction and, building upon it, the definition of differential simple systems. Subsection §3.4 contains a description of the differential THOMAS decomposition algorithm and the proof of its correctness and termination. Some implementation issues are discussed in §4, followed by a comparison of our implementation to some other implementations of triangular decompositions with the help of benchmarks.

2. Algebraic Systems

This section introduces the concepts of simple systems and the THOMAS decomposition for algebraic systems. These concepts are based on properties of the set of solutions of a system. We conclude the section with an algorithm for constructing a THOMAS decomposition.

Example 2.1. We give an easy example of a THOMAS decomposition. Consider the equation

\[ p = x^3 + (3y + 1)x^2 + (3y^2 + 2y)x + y^3 = 0. \]
A Thomas decomposition of \( \{ p = 0 \} \) is given by:

\[
S_1 := \{ \frac{x^3}{27y^3-4y} + (3y+1)x^2 + (3y^2+2y)x + y^3 = 0, \\
\frac{27y^3-4y}{6x^2} + (-27y^2+12y)x - 3y^2 + 2y = 0 \}
\]

The picture shows the solutions of \( \{ p = 0 \} \) in the real affine plane. The cardinality of the fibers of the projection onto the \( y \)-component depends on \( y \). However, if we consider all solutions in the complex plane, this cardinality is constant within each system, i.e., \( 3 \) and \( 2 \) in \( S_1 \) and \( S_2 \), respectively. This property is formalized in the definition of simple systems.

2.1 Preliminaries

Let \( F \) be a computable field of characteristic 0 and \( R := F[x_1, \ldots, x_n] \) be the polynomial ring in \( n \) variables. A total order \( \prec \) on \( \{1, x_1, \ldots, x_n\} \) with \( 1 < x_i \) for all \( i \) is called a ranking. The indeterminate \( x \) is called leader of \( p \in R \) if \( x \) is the \( < \)-largest variable occurring in \( p \). In this case we write \( \text{ld}(p) = x \). If \( p \in F \), we define \( \text{ld}(p) = 1 \). The degree of \( p \) in \( \text{ld}(p) \) is called main degree of \( p \) (\( m\text{deg}(p) \)) and the leading coefficient \( \text{init}(p) \in F[y \mid y < \text{ld}(p)] \) of \( \text{ld}(p)^{m\text{deg}(p)} \) in \( p \) is called initial of \( p \).

For \( a \in \overline{F}^n \), where \( \overline{F} \) denotes the algebraic closure of \( F \), define the following evaluation homomorphisms:

\[
\phi_a : F[x_1, \ldots, x_n] \rightarrow \overline{F} : x_i \mapsto a_i
\]

\[
\phi_{<x_k,a} : F[x_1, \ldots, x_n] \rightarrow \overline{F}[x_k, \ldots, x_n] : \begin{cases} x_i \mapsto a_i, & i < k \\ x_i \mapsto x_i, & \text{otherwise} \end{cases}
\]

Given a polynomial \( p \in R \), the symbols \( p_\prec \) and \( p_\prec \) denote the equation \( p = 0 \) and inequation \( p \neq 0 \), respectively. A finite set of equations and inequations is called an (algebraic) system over \( R \). Abusing notation, we sometimes treat \( p_\prec \) or \( p_\prec \) as the underlying polynomial \( p \). A solution of \( p_\prec \) or \( p_\prec \) is a tuple \( a \in \overline{F}^n \) with \( \phi_a(p) = 0 \) or \( \phi_a(p) \neq 0 \), respectively. We call \( a \in \overline{F}^n \) a solution of a system \( S \), if it is a solution of each element in \( S \). The set of all solutions of \( S \) is denoted by \( \mathcal{S}(S) \).

The subsets of all equations \( p_\prec \in S \) and all inequations \( p_\prec \in S \) are denoted by \( S^\prec \) and \( S^\prec \), respectively. Define \( S_x := \{ p \in S \mid \text{ld}(p) = x \} \). In a situation where it is clear that \( |S_x| = 1 \), we also write \( S_x \) to denote the unique element of \( S_x \). The subset \( S_{<x} := \{ p \in S \mid \text{ld}(p) < x \} \) is a system over \( F[ y \mid y < x ] \).

The Thomas approach uses the homomorphisms \( \phi_{<x,a} \) to treat each polynomial \( p \in S_x \) as the family of univariate polynomials \( \phi_{<x,a}(p) \in \overline{F}[x] \) for \( a \in \mathcal{S}(S_{<x}) \). This idea forms the basis of our central object, the simple system:

**Definition 2.2 (Simple Systems).** Let \( S \) be a system.

1. \( S \) is triangular if \( |S_x| \leq 1 \ \forall \ 1 \leq i \leq n \) and \( S \cap \{ e_\prec, e_\prec \mid e \in F \} = \emptyset \).
2. \( S \) has non-vanishing initials if \( \phi_a(\text{init}(p)) \neq 0 \ \forall \ a \in \mathcal{S}(S_{<x}) \) and \( p \in S_x \) for \( 1 \leq i \leq n \).
3. \( S \) is square-free \(^3\) if the univariate polynomial \( \phi_{<x,a}(p) \in \overline{F}[x] \) is square-free \( \forall a \in \mathcal{S}(S_{<x}) \) and \( p \in S_x \) for \( 1 \leq i \leq n \).

---

\(^2\)In the context of triangular decompositions, the leader is usually called main variable. The term leader is used in Thomas (1937) and has later been adopted in differential algebra.

\(^3\)Square-freeness has an important side-effect in the differential case. A square-free polynomial and its separant have no common roots. Thus, the separators do not vanish on solutions of the lower-ranking subsystems.
4. $S$ is called simple if it is triangular, has non-vanishing initials and is square-free.

Properties (2) and (3) are characterized via solutions of lower-ranking equations and inequations. However, the Thomas decomposition algorithm does not calculate roots of polynomials. Instead, it uses polynomial equations and inequations to partition the set of solutions of the lower-ranking system to ensure the above properties.

**Remark 2.3.** Every simple system has a solution. In particular, if $b \in \text{Sol}(S_{<x})$ and $S_x$ is not empty, then $\phi_{<x,b}(S_x)$ is a univariate polynomial with exactly $\text{mdeg}(S_x)$ distinct roots. When $S_x$ is an equation, each solution $b \in \text{Sol}(S_{<x})$ extends to a solution $(b, a) \in \text{Sol}(S_{\leq x})$ with $\text{mdeg}(S_x)$ possible choices $a \in \mathbb{F}$. Otherwise, all but finitely many $a \in \mathbb{F}$ yield a solution $(b, a) \in \text{Sol}(S_{\leq x})$, because an inequation $S_x$ excludes $\text{mdeg}(S_x)$ different $a$ and $S_x = \emptyset$ imposes no restriction on $a$.

Conversely, if $(a_1, \ldots, a_n) \in \text{Sol}(S)$ where $S$ is a system over $F[x_1, \ldots, x_n]$ with $x_1 < \ldots < x_n$, then $(a_1, \ldots, a_i) \in \text{Sol}(S_{\leq x_i})$.

To transform a system into a simple system, it is in general necessary to partition the set of solutions. This leads to a so-called decomposition into simple systems.

**Definition 2.4.** A family $(S_i)_{i=1}^n$ is called decomposition of $S$ if $\text{Sol}(S) = \bigcup_{i=1}^n \text{Sol}(S_i)$. A decomposition is called disjoint if $\text{Sol}(S_i) \cap \text{Sol}(S_j) = \emptyset \forall i \neq j$. A disjoint decomposition of a system into simple systems is called (algebraic) Thomas decomposition.

For any algebraic system $S$, there exists a Thomas decomposition (cf. Thomas (1937, 1962), Wang (1998)). The algorithm presented in the following section provides another proof of this fact.

**Example 2.5.** We compute a Thomas decomposition of $\{(p := ax^2 + bx + c) = \} \subset \mathbb{Q}[a, b, c, x]$ with respect to $a < b < c < x$. We highlight the highest power of the leader by underlining it.

First, we ensure that the initial $\text{init}(p)$ of $p$ is not zero. Therefore, we insert $(\text{init}(p)) \neq (a) \neq$ into the system. Since we restricted the solution set of this system, we also have to consider the system $\{(p), (a)\}$, which simplifies to $\{(bx + c), (a)\}$. Similarly, we add $(b) \neq$ to ensure $\text{init}(bx + c) \neq 0$ and get the special case system $\{(a), (b), (a)\}$. Up to this point, we have three systems, where the second and third one are easily checked to be simple:

\[
\begin{align*}
\mathbb{R} \times (a) & \downarrow (a)x^2 + bx + c) = \\
\mathbb{C} \times (b) & \downarrow (b)x + c) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\mathbb{C} \times (b) & \downarrow (b) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\mathbb{C} \times (b) & \downarrow (b) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\end{align*}
\]

Second, we ensure that $p$ is square-free by insertion of $(4a^2 - b^2) \neq$ into the first system. Again, we also need to consider the system $\{(p), (4a^2 - b^2), (a)\}$. As $p$ is a square in this system, we can replace it by its square-free part $2ax - b$. Now, all systems are easily verified to be simple and we obtain the following Thomas decomposition:

\[
\begin{align*}
\mathbb{R} \times (a) & \downarrow (a)x^2 + bx + c) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\mathbb{C} \times (b) & \downarrow (b) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\mathbb{C} \times (b) & \downarrow (b) = \\
\mathbb{C} \times (a) & \downarrow (a) = \\
\mathbb{C} \times (b) & \downarrow (b) = \\
\end{align*}
\]
2.2. Algebraic Thomas Decomposition

This section presents our main algorithm for algebraic systems and its subalgorithms. The algorithm represents each system as a pair consisting of a candidate simple system and a queue of unprocessed equations and inequations.\footnote{This approach has been adapted from Gerdt and Blinkov (1998b), where $T$ was an intermediate Janet basis and $Q$ a queue of new prolongations to be checked. A similar approach was later used for triangular decompositions in Moreno Maza (1999).} During each step, the algorithm chooses a suitable polynomial from the queue, pseudo-reduces it and afterwards combines it with the polynomial from the candidate simple system having the same leader. In this process, the algorithm may split the system, i.e., add a new polynomial into the queue as an inequation and at the same time create a new subsystem with the same polynomial added to the queue as an equation. This way, we ensure that no solutions are lost and the solution sets are disjoint. The algorithm considers a system inconsistent and discards it when an equation of the form $c = 0$ with $c \in F \setminus \{0\}$ or the inequation $0 \neq x$ is produced.

We consider a system $S$ as a pair of sets $(S_T, S_Q)$, where $S_T$ represents the candidate simple system and $S_Q$ is the queue. We require $S_T$ to be triangular and thus $(S_T)_x$ denotes the unique equation or inequation of leader $x$ in $S_T$, if any. Moreover, $S_T$ must fulfill a weaker form of the other two simplicity conditions, in particular, in conditions (2.2)(2) and (3), the tuple $a$ can be a solution of $(S_T)_c \cup (S_Q)_c$ instead of just $(S_T)_c$. Obviously, $S_Q = \emptyset$ implies simplicity of $S$.

From now on, let prem be a \textbf{pseudo remainder algorithm}\footnote{In our context prem does not necessarily have to be the classical pseudo remainder, but any sparse pseudo remainder with property (1) will suffice.} in $R$ and pquo the corresponding \textbf{pseudo quotient algorithm}. To be precise, if $p, q \in R$ with $\text{ld}(p) = \text{ld}(q) = x$, then

$$m \cdot p = \text{pquo}(p, q, x) \cdot q + \text{prem}(p, q, x)$$

(1)

holds, where $\deg_x(q) > \deg_x(\text{prem}(p, q, x))$, $\text{ld}(m) < x$ and $m \mid \text{init}(q)^k$ for some $k \in \mathbb{Z}_{\geq 0}$. Note that $\phi_a(\text{init}(p)) \neq 0$ and $\phi_a(\text{init}(q)) \neq 0$ imply $\phi_a(\text{pquo}(p, q, x)) \neq 0$ and $\phi_a(m) \neq 0$.

The following algorithm employs prem to reduce a polynomial modulo $S_T$:

\textbf{Algorithm 2.6 (Reduce).}
\textit{Input:} A system $S$, a polynomial $p \in R$
\textit{Output:} A polynomial $q$ with $\phi_a(p) = 0$ if and only if $\phi_a(q) = 0$ for each $a \in \mathcal{Sol}(S)$.
\textit{Algorithm:}
1: $x \leftarrow \text{ld}(p); q \leftarrow p$
2: \textbf{while} $x > 1$ and $(S_T)_x$ is an equation and $\text{mdeg}(q) \geq \text{mdeg}((S_T)_x)$ \textbf{do}
3: \hspace{1em} $q \leftarrow \text{prem}(q, (S_T)_x, x)$
4: \hspace{1em} $x \leftarrow \text{ld}(q)$
5: \textbf{end while}
6: \textbf{if} $x > 1$ and $\text{Reduce}(S, \text{init}(q)) = 0$ \textbf{then}
7: \hspace{1em} \textbf{return} $\text{Reduce}(S, q - \text{init}(q)x^{\text{mdeg}(q)})$
8: \textbf{else}
9: \hspace{1em} \textbf{return} $q$
10: \textbf{end if}

\textbf{Proof (Correctness).} There exist $m \in R \setminus \{0\}$ with $\text{ld}(m) < \text{ld}(p)$ and $\phi_a(m) \neq 0$ for all $a \in \mathcal{Sol}(S_{\leq \text{ld}(p)})$ such that

$$\text{Reduce}(S, p) = mp - \sum_{y \leq \text{ld}(p)} c_y \cdot (S_T)_y$$

with $c_y \in R$ and $\text{ld}(c_y) \leq \text{ld}(p)$ if $(S_T)_y$ is an equation and $c_y = 0$ otherwise. This implies

$$\phi_a(\text{Reduce}(S, p)) = \phi_a(m) \phi_a(p) - \sum_{y \leq x, \phi_a((S_T)_y) \neq 0} \phi_a(c_y) \phi_a((S_T)_y)$$
and therefore \( \phi_a(p) = 0 \) if and only if \( \phi_a(\text{Reduce}(S, p)) = 0 \).

Note that this algorithm only uses the equation part of the triangular system in \( S \), i.e. \( S_T \).

For ease of notation in the following algorithms, we write \( \text{Reduce}(S, p) \) instead of \( \text{Reduce}(S_T, p) \).

A polynomial \( p \) reduces to \( q \) modulo \( S_T \) if \( \text{Reduce}(S, p) = q \). A polynomial is reduced modulo \( S_T \) if it reduces to itself.

The \( \text{Reduce} \) algorithm differs slightly from the classical \( \text{prem}(p, S_T) \) as defined in Aubry et al. (1999). While \( \text{prem}(p, S_T) \) fully reduces \( p \) modulo all variables, \( \text{Reduce}(S, p) \) only reduces modulo the leader and ensures that the initial of the reduced form doesn’t vanish. Performing \( \text{Reduce}(S, p) \) in combination with a full coefficient reduction (see also §4.2) is the same as computing \( \text{prem}(p, S_T^p) \).

It is therefore possible to replace \( \text{Reduce}(S, p) \) with \( \text{prem}(p, S_T^p) \) in the following algorithms. Our approach adds some flexibility, as we can choose to omit a full reduction in an implementation. In particular, if a polynomial does not reduce to zero, we can determine that without performing a full \( \text{prem} \) reduction. We apply this multiple times in our implementation, most prominently in Algorithm (2.18). However, if a polynomial reduces to zero, \( \text{Reduce} \) has no advantage over \( \text{prem} \).

Later, we will use the following facts about the \( \text{Reduce} \) algorithm.

**Remark 2.7.** Let \( q = \text{Reduce}(S, p) \neq 0 \).

1. If \( \text{ld}(q) \) is an equation, then \( \text{mdeg}(q) < \text{mdeg}(\text{ld}(q)) \).

2. \( \text{Reduce}(S, \text{init}(\text{Reduce}(S, p))) \neq 0 \).

3. \( \text{ld}(q) \leq \text{ld}(p) \) and if \( \text{ld}(q) = \text{ld}(p) \), then \( \text{mdeg}(q) \leq \text{mdeg}(p) \).

The result of the \( \text{Reduce} \) algorithm does not need to be a canonical normal form, however, the algorithm recognizes polynomials that vanish on all solutions:

**Corollary 2.8.** Let \( p \in R \) with \( \text{ld}(p) = x \). \( \text{Reduce}(S, p) = 0 \) implies \( \phi_a(p) = 0 \ \forall \ a \in \mathfrak{Sol}(S_{\leq x}) \).

**Proof.** For all \( a \in \mathfrak{Sol}(S_{\leq x}) \), it holds that \( \phi_a(p) = 0 \) if and only if \( \phi_a(\text{Reduce}(S, p)) = 0 \). The statement follows from \( \phi_a(\text{Reduce}(S, p)) = \phi_a(0) = 0 \).

The converse of this corollary doesn’t hold in general. Thus, we provide two weaker statements in the following remark.

**Remark 2.9.** Let \( p \) and \( x \) as in Corollary (2.8).

1. If \( (S_Q)_{\leq x} = \emptyset \), i.e., \( S_{\leq x} = (S_T)_{\leq x} \) is simple, then \( \text{Reduce}(S, p) \neq 0 \) implies \( \exists \ a \in \mathfrak{Sol}(S_{\leq x}) \) such that \( \phi_a(p) \neq 0 \).

2. If \( (S_Q)_{\leq x} = \emptyset \) and \( \text{Reduce}(S, p) \neq 0 \) hold, then either \( \mathfrak{Sol}(S_{\leq x}) = \emptyset \) or \( \exists \ a \in \mathfrak{Sol}(S_{\leq x} \cup \{(S_T)_x\}) \) such that \( \phi_a(p) \neq 0 \).

**Proof.** We only prove the second part, as the first part easily follows.

Let \( (S_Q)_{\leq x} = \emptyset \), \( \text{Reduce}(S, p) \neq 0 \) and \( |\mathfrak{Sol}(S_{\leq x})| > 0 \). First, as \( \text{ld}((S_T)_x) = x \) and \( \text{mdeg}((S_T)_x) > 0 \), for each \( a \in \mathfrak{Sol}(S_{\leq x}) \), the univariate polynomial \( \phi_{\leq x,a}((S_T)_x) \in \overline{F}[x] \) has positive degree. Thus \( |\mathfrak{Sol}(S_{\leq x} \cup \{(S_T)_x\})| > 0 \).

Let \( \phi_a(p) = 0 \ \forall \ a \in \mathfrak{Sol}(S_{\leq x} \cup \{(S_T)_x\}) \). Then \( (S_T)_x \) is an equation and \( \text{deg}_x(p) \geq \text{deg}_x((S_T)_x) \) and therefore \( p \neq \text{Reduce}(S, p) \). In fact, (*) further implies \( \text{ld}(\text{Reduce}(S, p)) < x \), as otherwise \( \text{deg}_x(\text{Reduce}(S, p)) \geq \text{deg}_x((S_T)_x) \) would hold. By repeating the previous arguments, we can inductively conclude \( \text{ld}(\text{Reduce}(S, p)) = 1 \). As \( \phi_a(p) = 0 \), we conclude \( \text{Reduce}(S, p) = 0 \), a contradiction.

The first part of this remark in conjunction with Corollary (2.8) implies (Wang, 1998, Thm. 4).
Example 2.10. Reduce \( q_1 := x^2 + y^2 x + x + y \) modulo the simple system on the left.

\[
\begin{align*}
x & \quad S_x = (y^2 - 1) = x^2 + y^2 x + x + y =: q_1 \\
y & \quad S_y = (y^2 + 1) = y^2 + 1 =: q_3 \\
& \quad 0 = y^3 + y = \text{init}(q_2)
\end{align*}
\]

In the first reduction step, \( q_1 \) is pseudo-reduced modulo \( S_x \). The result \( q_2 \) still has leader \( x \), but a main degree smaller than \( S_x \). We determine that the initial of \( q_2 \) reduces to 0 and remove the highest power of \( x \) from \( q_2 \). The resulting polynomial \( q_3 \) now pseudo-reduces to 0 modulo \( S_y \), i.e. \( \text{Reduce} \{ S_x, S_y \}, q_1 \) = 0.

Now, we examine all splitting methods needed during the algorithm. We will use the following one-liner as subalgorithm for the splitting subalgorithms.

Algorithm 2.11 (Split). Input: A system \( S \), a polynomial \( p \in R \)

Output: The disjoint decomposition \((S \cup \{p_x\}, S \cup \{p=\})\) of \( S \).

Algorithm:
1: \textbf{return} \((S_T, S_Q \cup \{p_x\}), (S_T, S_Q \cup \{p=\})\)

For a better understanding of the following splitting subalgorithms we first need to explain how they are applied in the main algorithm. Each step of the algorithm treats a system \( S \) as follows. An equation or inequation \( q \) is chosen and removed from the queue \( S_Q \). Then we reduce \( q \) modulo \( S_T \). For the simplicity properties to hold w.r.t. \( q \) it is necessary to add inequations to \( S \). To accomplish this, we pass \( S \) together with \( q \) to the splitting subalgorithms. Each such subalgorithm returns two systems. The first system \( S_1 \) contains an additional inequation. The second system \( S_2 \) contains a complementary equation, \( q \) is added back into the queue of \( S_2 \), and \( S_2 \) is put aside for later treatment. In each case \((S_1 \cup \{q\}, S_2)\) is a disjoint decomposition of the original system \( S \cup \{q\} \). Then \( S_1 \) and \( q \) may be subjected to further splitting algorithms and eventually \( q \) is added into the candidate simple system.

The first splitting algorithm we consider is \text{InitSplit}, which is concerned with property (2.2)(2).

Algorithm 2.12 (InitSplit). Input: A system \( S \), an equation or inequation \( q \) with \( \text{ld}(q) = x \).

Output: Two systems \( S_1 \) and \( S_2 \), where \((S_1 \cup \{q\}, S_2)\) is a disjoint decomposition of \( S \cup \{q\} \).

Moreover, \( \phi_a(\text{init}(q)) \neq 0 \) holds for all \( a \in \mathbb{G}(S_1) \) and \( \phi_a(\text{init}(q)) = 0 \) for all \( a \in \mathbb{G}(S_2) \).

Algorithm:
1: \((S_1, S_2) \leftarrow \text{Split}(S, \text{init}(q))\)
2: \((S_2)_Q \leftarrow (S_2)_Q \cup \{q\}\)
3: \textbf{return} \((S_1, S_2)\)

For the further splitting algorithms, we need some preparation. In Definition (2.2) we consider a multivariate polynomial \( p \) as the family of univariate polynomials \( \phi_{<\text{ld}(p)}, a(p) \). For ensuring triangularity and square-freeness, we have to compute the gcd (greatest common divisor) of two polynomials, which in general depends on \( a \). Subresultants provide a generalization of the Euclidean algorithm and enable us to take the tuple \( a \) into account.

Definition 2.13. Let \( p, q \in R \) with \( \text{ld}(p) = \text{ld}(q) = x \), \( \deg_x(p) = d_p > \deg_x(q) = d_q \). We denote by \( \text{PRS}(p, q, x) \) the \textbf{subresultant polynomial remainder sequence} (see Habicht \(1948 \), (Mishra, 1993, Chap. 7), (Yap, 2000, Chap. 5)) of \( p \) and \( q \) w.r.t. \( x \), and by \( \text{PRS}_i(p, q, x) \), \( i < d_q \) the regular polynomial of degree \( i \) in \( \text{PRS}(p, q, x) \) if it exists, or 0 otherwise. Furthermore, \( \text{PRS}_{d_p}(p, q, x) := p \), \( \text{PRS}_{d_q}(p, q, x) := q \) and \( \text{PRS}_i(p, q, x) := 0 \), \( d_q < i < d_p \).
Define \( \text{res}_i(p, q, x) := \text{init}(\text{PRS}_i(p, q, x)) \) for \( 0 < i < d_p \), \( \text{res}_d(p, q, x) := 1 \) and \( \text{res}_0(p, q, x) := \text{PRS}_0(p, q, x) \). Note that \( \text{res}_0(p, q, x) \) is the usual resultant.\(^6\)

The initials of the subresultants provide conditions to determine the degrees of all possible gcds. Using these conditions, we describe the splittings necessary to determine degrees of polynomials within one system.

**Definition 2.14.** Let \( S \) be a system and \( p_1, p_2 \in R \) with \( \text{ld}(p_1) = \text{ld}(p_2) = x \). If \( |\mathcal{Sol}(S_{<x})| > 0 \), we call

\[
i := \min \{ i \in \mathbb{Z}_{\geq 0} \mid \exists a \in \mathcal{Sol}(S_{<x}) \text{ such that } \deg_s(\gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2))) = i\}
\]

the fiber cardinality of \( p_1 \) and \( p_2 \) w.r.t. \( S \). Moreover, if \( (S_Q)_{<x}^\sim = \emptyset \), then

\[
i' := \min \{ i \in \mathbb{Z}_{\geq 0} \mid \text{Reduce}(\text{res}_i(p_1, p_2, x), S_T) = 0 \forall j < i \text{ and } \text{Reduce}(\text{res}_i(p_1, p_2, x), S_T) \neq 0 \}
\]

is the quasi fiber cardinality of \( p_1 \) and \( p_2 \) w.r.t. \( S \). A disjoint decomposition \( (S_1, S_2) \) of \( S \) such that

1. \( \deg_s(\gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2))) = i \forall a \in \mathcal{Sol}((S_1)_{<x}) \)
2. \( \deg_s(\gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2))) > i \forall a \in \mathcal{Sol}((S_2)_{<x}) \)

is called \( i \)-th fibration split of \( p_1 \) and \( p_2 \) w.r.t. \( S \). A polynomial \( r \in R \) with \( \text{ld}(r) = x \) such that \( \deg_s(r) = i \) and

\[
\phi_{<x,a}(r) \sim \gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2)) \forall a \in \mathcal{Sol}((S_1)_{<x})
\]

is called \( i \)-th conditional greatest common divisor of \( p_1 \) and \( p_2 \) w.r.t. \( S \), where \( p \sim q \) if and only if \( p \in (\mathcal{F} \setminus \{0\}) q \). Furthermore, \( q \in R \) with \( \text{ld}(q) = x \) and \( \deg_s(q) = \deg_s(p_1) - i \) such that

\[
\phi_{<x,a}(q) \sim \frac{\phi_{<x,a}(p_1)}{\gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2))} \forall a \in \mathcal{Sol}((S_1)_{<x})
\]

is called the \( i \)-th conditional quotient of \( p_1 \) by \( p_2 \) w.r.t. \( S \). By replacing \( \phi_{<x,a}(p_2) \) in the above definition with \( \frac{\partial}{\partial x}(\phi_{<x,a}(p_1)) \), we get an \( i \)-th square-free split and \( i \)-th conditional square-free part of \( p_1 \) w.r.t. \( S \).

**Example 2.15.** Consider the system \( S := \{x^3 + y\} \) and the polynomial \( q := x^2 + x + y + 1 \) with \( y < x \). Compute \( \text{res}_0(S_x, q) = y^3 + 7y^2 + 5y + 1 \), \( \text{res}_1(S_x, q) = -y \) and \( \text{res}_2(S_x, q) = 1 \). The fiber cardinality is of \( S_x \) and \( q \) w.r.t. \( S \) is 0. A zeroth fibration split is given by \( S_1 := S \cup \{ (\text{res}_0(S_x, q))_x \} \) and \( S_2 := S \cup \{ (\text{res}_2(S_x, q))_x \} \). The fiber cardinality w.r.t. \( S_2 \) is 1. A first fibration split is given by \( S_{2,1} := S_2 \cup \{ (-y)_x \} \) and \( S_{2,2} := S \cup \{ (-y)_x \} \). Note in this case that \( \mathcal{Sol}(S_{2,1}) = \mathcal{Sol}(S_2) \) and \( \mathcal{Sol}(S_{2,2}) = \emptyset \). A zeroth conditional quotient of \( S_x \) and \( q \) is \( S_x \). A first conditional gcd and first conditional quotient are \( -yx^2 + 2y + 1 \) and \( y^2x^2 + (2y^2 + y)x + 4y^2 + 4y + 1 \), respectively.

It is in general hardly possible to compute the fiber cardinality directly. However, in the case where the quasi fiber cardinality is strictly smaller than the fiber cardinality, the corresponding fibration split will lead to one inconsistent system, and one where the quasi fiber cardinality is increased.

**Lemma 2.16.** Let \( |\mathcal{Sol}(S_{<x})| > 0 \) and \( (S_Q)_{<x}^\sim = \emptyset \). For \( p_1, p_2 \) as in Definition 2.14 with \( \phi_a(\text{init}(p_1)) \neq 0 \forall a \in \mathcal{Sol}(S_{<x}) \) and \( \text{mdeg}(p_1) > \text{mdeg}(p_2) \), let \( i \) be the fiber cardinality of \( p_1 \) and \( p_2 \) w.r.t. \( S \) and \( i' \) the corresponding quasi fiber cardinality. Then

\[
i' \leq i
\]

where the equality holds if and only if \( |\mathcal{Sol}(S_{<x} \cup \{ \text{res}_i(p_1, p_2, x)_x \})| > 0 \).

---

\(^6\)These definitions are slightly different from the ones cited in the literature (Mishra, 1993, Chap. 7), (Yap, 2000, Chap. 3), since we only use the regular subresultants. However, it is easy to see that all theorems from Mishra, 1993, Chap. 7) we refer to still hold for \( i < d_q \).
PROOF. Let \( a \in S\mathfrak{ol}(S_{<x}) \), \( \text{mdeg}(p_1) > \text{mdeg}(p_2) \), \( d_{p_1} := \text{deg}_x(p_1) = \text{deg}_x(\phi_{<x,a}(p_1)) \), \( d_{p_2} := \text{deg}_x(p_2) \) and \( d_{p_2,a} := \text{deg}_x(\phi_{<x,a}(p_2)) \). If \( i < \max(d_{p_1}, d_{p_2,a}) - 1 = d_{p_1} - 1 \), then (Mishra, 1993, Thm. 7.8.1) implies
\[
\phi_{<x,a}(\text{PRS}_i(p_1, p_2, x)) \sim \text{PRS}_i(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2), x)
\]
and
\[
\phi_a(\text{res}_i(p_1, p_2, x)) = 0 \iff \text{res}_i(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2), x) = 0 .
\]

Conditions (2) and (3) by definition also hold for the trivial cases \( d_{p_2} \leq i \leq d_{p_1} \).

For all indices \( j < i' \), Corollary (2.8) and the fact \( \text{Reduce}(\text{res}_j(p_1, p_2, x), S_T) = 0 \) imply \( \phi_a(\text{res}_j(p_1, p_2, x)) = 0 \). By (2) and (3), \( \text{res}_j(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2), x) = 0 \) follows. We apply (Mishra, 1993, Thm. 7.10.5) successively and get \( \text{PRS}_j(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2), x) = 0 \). Thus,
\[
\text{deg}_x(\gcd(\phi_{<x,a}(p_1), \phi_{<x,a}(p_2))) \geq i'
\]
holds. This implies \( i' \leq i \).

Equality in (4) holds if and only if there exists \( a \in S\mathfrak{ol}(S_{<x}) \) such that \( \phi_a(\text{res}_i(p_1, p_2, x)) \neq 0 \). Therefore, \( i = i' \) if and only if \( |S\mathfrak{ol}(S_{<x} \cup \{\text{res}_i(p_1, p_2, x)\})| > 0 \).

The above lemma doesn’t apply if both polynomials have the same degree. In this case, both polynomials must have non-vanishing initials, as shown in the following corollary.

**Corollary 2.17.** Let \( |S\mathfrak{ol}(S_{<x})| > 0 \) and \( (S_Q)^{=-}_{S_{<x}} = 0 \). For polynomials \( p_1, p_2 \) as in Definition (2.14) with \( \phi_a(\text{init}(p_1)) \neq 0 \) and \( \phi_a(\text{init}(p_2)) \neq 0 \) \( \forall a \in S\mathfrak{ol}(S_{<x}) \), let \( i \) be the fiber cardinality of \( p_1 \) and \( p_2 \) w.r.t. \( S \) and \( i' \) the quasi fiber cardinality of \( p_1 \) and \( \text{prem}(p_2, p_1, x) \) w.r.t. \( S \). Then
\[
i' \leq i
\]
with equality if and only if \( |S\mathfrak{ol}(S_{<x} \cup \{\text{res}_i(p_1, \text{prem}(p_2, p_1, x), x)\})| > 0 \).

**Proof.** Let \( a \in S\mathfrak{ol}(S_{<x}) \). By the assumption on the initials, (Mishra, 1993, Corr. 7.5.6) implies \( \phi_{<x,a}(\text{prem}(p_2, p_1, x)) = \text{prem}(\phi_{<x,a}(p_2), \phi_{<x,a}(p_1), x) \). The univariate polynomials \( \phi_{<x,a}(p_1) \) and \( \phi_{<x,a}(p_2) \) have the same gcd as \( \phi_{<x,a}(p_1) \) and \( \text{prem}(\phi_{<x,a}(p_2), \phi_{<x,a}(p_1), x) \). We can therefore replace \( p_2 \) with \( \text{prem}(p_2, p_1, x) \) in Lemma (2.16).

The following algorithm computes the quasi fiber cardinality of two polynomials.

**Algorithm 2.18 (ResSplit).** Input: A system \( S \) with \( (S_Q)^{=-}_{S_{<x}} = 0 \), two polynomials \( p, q \in R \) with \( \text{ld}(p) = \text{ld}(q) = x \), \( \text{mdeg}(p) > \text{mdeg}(q) \) and \( \phi_a(\text{init}(p)) \neq 0 \) for all \( a \in S\mathfrak{ol}(S_{<x}) \).
Output: The quasi fiber cardinality \( i \) of \( p \) and \( q \) w.r.t. \( S \) and an \( i \)-th fibration split \( (S_1, S_2) \) of \( p \) and \( q \) w.r.t. \( S \).
Algorithm:
1: \( i \leftarrow \min\{i \in \mathbb{Z}_{\geq 0} \mid \text{Reduce}(\text{res}_j(p, q, x), S_T) = 0 \ \forall \ j < i \ and \ \text{Reduce}(\text{res}_i(p, q, x), S_T) \neq 0 \} \)
2: **return** \( (i, S_1, S_2) := (i, \text{Split}(S, \text{res}_i(p, q, x))) \)

**Proof (Correctness).** Assume \( |S\mathfrak{ol}((S_i)_{<x})| > 0, l = 1, 2 \), as the statement is trivial otherwise.

Let \( a \in S\mathfrak{ol}((S_i)_{<x}) \). The polynomial \( g := \text{PRS}_i(\phi_{<x,a}(p), \phi_{<x,a}(q), x) \) is not identically zero, due to \( (\text{init}(g))_x \neq (\text{res}_i(p, q, x))_x \in (S_i)_Q \). The degree of \( g \) is \( i \) and \( g \sim \gcd(\phi_{<x,a}(p), \phi_{<x,a}(q)) \), as discussed in the proof of Lemma (2.16).

Let \( a \in S\mathfrak{ol}((S_2)_{<x}) \). (Mishra, 1993, Thm. 7.10.5) and \( (\text{init}(g))_x = (\text{res}_i(p, q, x))_x \in (S_2)_Q \) imply \( g \equiv 0 \). Therefore, \( \text{deg}_x(\gcd(\phi_{<x,a}(p), \phi_{<x,a}(q))) > i \).

We apply the fiber cardinality and fibration split to compute a greatest common divisor of an existing polynomial in \( S_T \) and another polynomial.
Algorithm 2.19 (ResSplitGCD). \textit{Input:} A system \(S\) with \((S_Q)_x = 0\), where \((S_T)_x\) is an equation, and an equation \(q=\) with \(\text{ld}(q) = x\). Furthermore, \(\text{mdeg}(q) < \text{mdeg}((S_T)_x)\).
\textit{Output:} Two systems \(S_1\) and \(S_2\) and an equation \(\tilde{q}\) such that:
\begin{enumerate}[(a)]  
  \item \(S_2 = \tilde{S}_2 \cup \{q\} \) where \(\left( S_1, \tilde{S}_2 \right) \) is an \(i\)-th fibration split of \((S_T)_x\) and \(q\) w.r.t. \(S\),
  \item \(\tilde{q}\) is an \(i\)-th conditional \(\text{gcd}\) of \((S_T)_x\) and \(q\) w.r.t. \(S\),
\end{enumerate}
where \(i\) is the quasi fiber cardinality of \(p\) and \(q\) w.r.t. \(S\).

\textbf{Algorithm:}
1: \((i, S_1, S_2) \leftarrow \text{ResSplit}(S, (S_T)_x, q)\)
2: \((S_2)_Q \leftarrow (S_2)_Q \cup \{q\}\)
3: \textbf{return} \(S_1, S_2, \text{PRS}_i((S_T)_x, q, x)\)

\textbf{Proof (Correctness).} Property (a) follows from Algorithm (2.18) and line 2. Property (b) was already shown in the correctness proof of Algorithm (2.18).

Note that \(i > 0\) is required in this case, as \(i = 0\) would yield an inconsistency. Therefore, before calling \text{ResSplitGCD}, we will always ensure this condition in the main algorithm by incorporating the resultant of two equations into the system.

The following algorithm is similar. But instead of the \(\text{gcd}\), it returns the first input polynomial divided by the \(\text{gcd}\).

Algorithm 2.20 (ResSplitDivide). \textit{Input:} A system \(S\) with \((S_Q)_x = 0\) and two polynomials \(p, q\) with \(\text{ld}(p) = \text{ld}(q) = x\) and \(\phi_a(\text{init}(p)) \neq 0\) for all \(a \in \text{Sol}(S_{<x})\). Furthermore, if \(\text{mdeg}(p) \leq \text{mdeg}(q)\) then \(\phi_a(\text{init}(q)) \neq 0\).
\textit{Output:} Two systems \(S_1\) and \(S_2\) and a polynomial \(\bar{p}\) such that:
\begin{enumerate}[(a)]  
  \item \(S_2 = \tilde{S}_2 \cup \{q\} \) where \(\left( S_1, \tilde{S}_2 \right) \) is an \(i\)-th fibration split of \(p\) and \(q'\) w.r.t. \(S\),
  \item \(\bar{p}\) is an \(i\)-th conditional quotient of \(p\) by \(q'\) w.r.t. \(S\),
\end{enumerate}
where \(i\) is the quasi fiber cardinality of \(p\) and \(q'\) w.r.t. \(S\), with \(q' = q\) for \(\text{mdeg}(p) > \text{mdeg}(q)\) and \(q' = \text{prem}(q, p, x)\) otherwise.

\textbf{Algorithm:}
1: \textbf{if} \(\text{mdeg}(p) \leq \text{mdeg}(q)\) \textbf{then}
2: \textbf{return} \text{ResSplitDivide}(S, p, \text{prem}(q, p, x))
3: \textbf{else}
4: \((i, S_1, S_2) \leftarrow \text{ResSplit}(S, p, q)\)
5: \textbf{if} \(i > 0\) \textbf{then}
6: \(\bar{p} \leftarrow \text{pquo}(p, \text{PRS}_i(p, \text{prem}(q, p, x), x), x)\)
7: \textbf{else}
8: \(\bar{p} \leftarrow p\)
9: \textbf{end if}
10: \((S_2)_Q \leftarrow (S_2)_Q \cup \{q\}\)
11: \textbf{return} \(S_1, S_2, \bar{p}\)
12: \textbf{end if}

\textbf{Proof (Correctness).} According to Corollary (2.17), we can without loss of generality assume \(\text{mdeg}(p) > \text{mdeg}(q)\).

Property (a) follows from Algorithm (2.18) and line 10. For all \(a \in \text{Sol}(S_1)\), the following holds: If \(i = 0\), then \(\deg_x(\gcd(\phi_{<x,a}(p), \phi_{<x,a}(q'))) = 0\) and thus \(\phi_{<x,a}(p)\) shares no roots with \(\phi_{<x,a}(q')\). Now let \(i > 0\). Formula (1) implies
\[
m \cdot p = \bar{p} \cdot \text{PRS}_i(p, q', x) + \text{prem}(p, \text{PRS}_i(p, q', x), x)\ .
\]
Due to (Mishra, 1993, Cor. 7.5.6) and (2), (3) there exist $k_1, k_2 \in F \setminus \{0\}$ such that

$$
\phi_{<x,a}(m) \cdot \phi_{<x,a}(p) \\
= \phi_{<x,a}(\tilde{p}) \cdot \phi_{<x,a}(\text{PRS}_i(p,q,x)) + \phi_{<x,a}(\text{prem}(p,\text{PRS}_i(p,q,x),x)) \\
= \phi_{<x,a}(\tilde{p}) \cdot k_1 \text{PRS}_i(\phi_{<x,a}(p),\phi_{<x,a}(q),x) + k_2 \text{prem}(\phi_{<x,a}(p),\text{PRS}_i(\phi_{<x,a}(p),\phi_{<x,a}(q),x),x) \\
= \phi_{<x,a}(\tilde{p}) \cdot k_1 \gcd(\phi_{<x,a}(p),\phi_{<x,a}(q)) + 0 .
$$

Thus, we obtain property b) from

$$
\phi_{<x,a}(\tilde{p}) \sim \frac{\phi_{<x,a}(p)}{\gcd(\phi_{<x,a}(p),\phi_{<x,a}(q))}
$$

and $\deg_x(\phi_{<x,a}(\tilde{p})) = \deg_x(\phi_{<x,a}(p)) - \deg_x(\gcd(\phi_{<x,a}(p),\phi_{<x,a}(q))) = \deg_x(p) - i$. \hfill \Box

Applying the last algorithm to a polynomial $p$ and $\frac{\partial}{\partial x}p$ yields an algorithm to make $p$ square-free. We present it separately for better readability of the main algorithm.

**Algorithm 2.21** (ResSplitSquareFree). *Input:* A system $S$ with $(S_Q)^{\perp}_x = \emptyset$ and a polynomial $p$ with $\text{ld}(p) = x$ and $\phi_a(\text{init}(p)) \neq 0$ for all $a \in \mathcal{S}_c(S_{\leq x})$.

*Output:* Two systems $S_1$ and $S_2$ and a polynomial $r$ such that:

**a)** $S_2 = \overline{S_2} \cup \{p\}$ where $(S_1, \overline{S_1})$ is an $i$-th square-free split of $p$ w.r.t. $S$,

**b)** $r$ is an $i$-th conditional square-free part of $p$ w.r.t. $S$.

*Algorithm*:

1. $(i, S_1, S_2) \leftarrow \text{ResSplit}(S,p, \frac{\partial}{\partial x}p)$
2. *if* $i > 0$ *then*
3. *else*
4. *end if*
5. $(S_2)_Q \leftarrow (S_2)_Q \cup \{p\}$
6. *return* $S_1, S_2, r$

*Proof (Correctness).* Since $\phi_{<x,a}(\frac{\partial}{\partial x}p) = \frac{\partial}{\partial x} \phi_{<x,a}(p)$, an $i$-th square-free split of $p$ is an $i$-th fibration split of $p$ and $\frac{\partial}{\partial x}p$. The rest follows from the proof of Algorithm (2.20). \hfill \Box

In all ResSplit-based algorithms, $(S_Q)^{\perp}_x = \emptyset$ is required. This ensures that all equations of a smaller leader than $x$ will be respected by reduction modulo $S_T$. The order in which polynomials are treated by the main algorithm must therefore be restricted.

**Definition 2.22** (Select). *Let $\mathcal{P}_{finite}(M)$ be the set of all finite subsets of a set $M$. A selection strategy* is a map

$$
\text{Select} : \mathcal{P}_{finite}(\{p_\neq, p_\neq | p \in R\}) \rightarrow \{p_\neq, p_\neq | p \in R\} : \\
Q \leftrightarrow \begin{cases} q \in Q 
\end{cases}
$$

*with the following properties:*

1. *If* $\text{Select}(Q) = q_\neq$ *is an equation, then* $Q^{\perp}_{\leq \text{ld}(q)} = \emptyset$.
2. *If* $\text{Select}(Q) = q_\neq$ *is an inequation, then* $Q^{\perp}_{\leq \text{ld}(q)} = \emptyset$.

11
We demonstrate that these conditions are necessary for termination of our approach, by giving an example where we violate them.

**Example 2.23.** Consider \( R := F[a,x] \) with \( a < x \) and the system \( S \) with \( S_T := \emptyset \) and \( S_Q := \{(x^2 - a)_\equiv \} \). To insert \( (x^2 - a)_\equiv \) into \( S_T \), we need to apply the ResSplitSquareFree algorithm: We calculate \( \text{res}_0(x^2 - a, 2x, x) = -4a \), \( \text{res}_1(x^2 - a, 2x, x) = 2 \) and \( \text{res}_2(x^2 - a, 2x, x) = 1 \) according to Definition (2.13). The quasi fiber cardinality is 0 and we get the two new systems \( S_1, S_2 \) with

\[
(S_1)_T = \{(x^2 - a)_\equiv \}, (S_1)_Q = \{(-4a)_\neq \} \quad \text{and} \quad (S_2)_T = \emptyset, (S_2)_Q = \{(x^2 - a)_=, (-4a)_\equiv \} .
\]

We now consider what happens with \( S_2 \): If we select \( (x^2 - a)_\equiv \) as the next equation to be treated, in violation of the properties in Definition (2.22), ResSplitSquareFree will split up \( S_2 \) into \( S_{2,1}, S_{2,2} \) with

\[
(S_{2,1})_T = \{(x^2 - a)_\equiv \}, (S_{2,1})_Q = \{(-4a)_\neq, (-4a)_\equiv \}
\]

and

\[
(S_{2,2})_T = \emptyset, (S_{2,2})_Q = \{(x^2 - a)_=, (-4a)_\equiv \} .
\]

As \( S_2 = S_{2,2} \), this will lead to an endless loop.

The following trivial algorithm inserts a new equation into \( S_T \). It will be replaced with a different algorithm in §3 when the differential Thomas decomposition is considered.

**Algorithm 2.24 (InsertEquation).** Input: A system \( S \) and an equation \( r_\equiv \) with \( \text{ld}(r) = x \) satisfying \( \phi_a(\text{init}(r)) \neq 0 \) and \( \phi_{<x,a}(r) \) square-free for all \( a \in \mathfrak{Sol}(S_{<x}) \). Output: A system \( S \) where \( r_\equiv \) is inserted into \( S_T \).

Algorithm:

1. if \( (S_T)_x \) is not empty then
2. \( S_T \leftarrow (S_T \setminus (\{(S_T)_x\})) \)
3. end if
4. \( S_T \leftarrow S_T \cup \{r_\equiv\} \)
5. return \( S \)

Now we present the main algorithm. The general structure is as follows: In each iteration, a system \( S \) is selected from a list \( P \) of unfinished systems. An equation or inequation \( q \) is chosen from the queue \( S_Q \) according to the selection strategy. Then \( q \) is reduced modulo \( S_T \) and incorporated into the candidate simple system \( S_T \) with the splitting algorithms as described above. In doing so, the algorithm may add new systems \( S_i \) to \( P \). As soon as the algorithm produces a system containing an equation \( c_\equiv \) for \( c \in F \setminus \{0\} \) or the inequation \( 0_\neq \), this system is discarded.

**Algorithm 2.25 (Decompose).** The algorithm is printed on page 13.

We demonstrate the algorithm with a simple example. Note, that we will omit systems which are obviously inconsistent.

**Example 2.26.** Let \( S = (S_T, S_Q) := (\emptyset, \{(x^2 + x + 1)_\equiv, (x + a)_\equiv \}) \) with \( a < x \). According to Select, \( q := (x^2 + x + 1)_\equiv \) is chosen. As \( \text{init}(q) = 1 \) and \( \text{res}_0(q, \frac{\partial}{\partial q}, q, x) = 1 \), the original system \( S \) is replaced by \( \{(x^2 + x + 1)_\equiv, (x + a)_\equiv \} \).

Now, \( q := (x + a)_\equiv \) is selected and ResSplitDivide\((S, (S_T)_x, q)\) computes \( \text{res}_0((S_T)_x, q, x) = \text{prem}((S_T)_x, q, x) = a^2 - a + 1 \), \( \text{res}_1((S_T)_x, q, x) = \text{init}(q) = 1 \), and \( \text{res}_2((S_T)_x, q, x) = 1 \). As \( S_T \) contains no equation of leader \( a \), none of these polynomials can be reduced. Then, we decompose \( S \) into

\[
S := \{(x^2 + x + 1)_=, (a^2 - a + 1)_\equiv \}, \{\} \ .
\]
Algorithm 2.25 (Decompose)

Input: A system $S'$ with $(S')_T = \emptyset$.
Output: A Thomas decomposition of $S'$.

Algorithm:
1. $P \leftarrow \{S'\}$; $Result \leftarrow \emptyset$
2. while $|P| > 0$ do
3.  Choose $S \in P$; $P \leftarrow P \setminus \{S\}$
4.  if $|S_Q| = 0$ then
5.     $Result \leftarrow Result \cup \{S\}$
6.  else
7.     $q \leftarrow Select(S_Q); S_Q \leftarrow S_Q \setminus \{q\}$
8.     $q \leftarrow Reduce(q, S_T); x \leftarrow \text{id}(q)$
9.     if $q \notin \{0_\neq, c_\neq | c \in F \setminus \{0\}\}$ then
10.    if $x \neq 1$ then
11.       if $q$ is an equation then
12.          if $\text{Reduce}(\text{res}_0((S_T)_x, q, x), S_T) = 0$ then
13.              $(S, S_1, p) \leftarrow \text{ResSplitGCD}(S, q, x); P \leftarrow P \cup \{S_1\}$
14.              $S \leftarrow \text{InsertEquation}(S, p_\neq)$
15.          else
16.              $S_Q \leftarrow S_Q \cup \{q_\neq, \text{res}_0((S_T)_x, q, x)_\neq\}$
17.          end if
18.       end if
19.   end if
20.   else if $q$ is an inequation then
21.     $S_Q \leftarrow S_Q \cup \{(S_T)_x\}; S_T \leftarrow S_T \setminus \{(S_T)_x\}$
22.   end if
23.   $(S, S_2) \leftarrow \text{InitSplit}(S, q); P \leftarrow P \cup \{S_2\}$
24.   $(S, S_3, p) \leftarrow \text{ResSplitSquareFree}(S, q); P \leftarrow P \cup \{S_3\}$
25.   $S \leftarrow \text{InsertEquation}(S, p_\neq)$
26. end if
27. end else if $q$ is an inequation then
28. if $(S_T)_x$ is an equation then
29.     $(S, S_4, p) \leftarrow \text{ResSplitDivide}(S, (S_T)_x, q); P \leftarrow P \cup \{S_4\}$
30.     $S \leftarrow \text{InsertEquation}(S, p_\neq)$
31. else
32.     $(S, S_5) \leftarrow \text{InitSplit}(S, q); P \leftarrow P \cup \{S_5\}$
33.     $(S, S_6, p) \leftarrow \text{ResSplitSquareFree}(S, q); P \leftarrow P \cup \{S_6\}$
34.     if $(S_T)_x$ is an inequation then
35.         $(S, S_7, r) \leftarrow \text{ResSplitDivide}(S, (S_T)_x, p); P \leftarrow P \cup \{S_7\}$
36.     end if
37.     end if
38.     $(S_T)_x \leftarrow (r \cdot p)_\neq$
39. end if
40. end if
41. end if
42. end if
43. $P \leftarrow P \cup \{S\}$
44. end if
45. end if
46. end while
47. return $Result$

*a*Remember that $(S_T)_x$ might be empty, and thus neither an equation nor an inequation.
which is already simple, and

\[
S_1 := ((x^2 + x + 1)_=, (x + a)_x, (a^2 - a + 1)_=) .
\]

We replace \( S_1 \) by

\[
S_1 := ((x^2 + x + 1)_=, (a^2 - a + 1)_=, (x + a)_x)
\]

and apply \( \text{ResSplitDivide}(S_1, ((S_1)_T, x), q) \) to \( S_1 \) again. This time, \( \text{Reduce}(a^2 - a + 1, (S_1)_T) = 0 \) holds and \( S_1 \) is replaced with

\[
S_1 := ((x - a + 1)_=, (a^2 - a + 1)_=, \{1\} ) .
\]

Finally, a Thomas decomposition of \( S \) is:

\[
((x^2 + x + 1)_=, (a^2 - a + 1)_x, (x - a + 1)_=, (a^2 - a + 1)_=) .
\]

**Proof (Correctness).** First, note that it is easily verified that the input specifications of all subalgorithms are fulfilled (in particular, for lines 14 and 29, cf. Remark (2.7)(1)).

The correctness of the **Decompose** algorithm is proved by verifying two loop invariants:

1. \( P \cup \text{Result} \) is a disjoint decomposition of the input \( S’ \).
2. For all systems \( S \in P \cup \text{Result}, S_T \) is triangular and
   \[
   \begin{align*}
   & (a) \phi_{<x,a}(p) \text{ is square-free and} \\
   & (b) \phi_a(\text{init}(p)) \neq 0
   \end{align*}
   \]
   for all \( p \in S_T \) with \( \text{ld}(p) = x \) and all \( a \in \text{Sol}( (S_T)_<x \cup (S_Q)_<x) \).

We begin with proving the first loop invariant. Assume that \( P \cup \text{Result} \) is a disjoint decomposition of \( S’ \) at the beginning of the main loop. It suffices to show that all systems we add to \( P \) or \( \text{Result} \) add up to a disjoint decomposition of the system \( S \), that is chosen in line 3. If \( S_Q = \emptyset \) holds in line 4, the algorithm just moves \( S \) from \( P \) to \( \text{Result} \).

In line 17, adding \( \text{res}_0((S_T)_T, q, x)_T \) to \( S \) does not change the solutions of \( S \), as \( \phi_{<x,a}((S_T)_T) = 0 \) and \( \phi_a(q) = 0 \) for each \( a \in F[y \mid y < x] \) implies \( \phi_a(\text{res}_0(p, q, x)) = 0 \) (cf. (Mishra, 1993, Lemma 7.2.3)).

Note now that if \( (S, S_1) \) is the output of any of the \( \text{ResSplitGcd}, \text{InitSplit}, \text{ResSplitSquareFree} \) and \( \text{ResSplitDivide} \) algorithms, then \( (S \cup \{q\}, S_1) \) is a disjoint decomposition of \( S_0 \cup \{q\} \), where \( S_0 \) is the input of the respective algorithm. It remains to be shown that the actions performed in lines 15, 25, 30, 36 and 38 are equivalent to putting \( q \) back into the system \( S \).

Let \( a \in \text{Sol}(S_{<x}) \). In the context of line 15, Algorithm (2.19) guarantees

\[
\phi_{<x,a}(p) = 0 \iff \phi_{<x,a}((S_T)_x) = 0 \quad \text{and} \quad \phi_{<x,a}(q) = 0 .
\]

In the context of line 30, Algorithm (2.20) ensures that

\[
\phi_{<x,a}(p) = 0 \iff \phi_{<x,a}((S_T)_x) = 0 \quad \text{and} \quad \phi_{<x,a}(q) \neq 0 .
\]

In lines 25, 36 and 38, \( p \) has the same solutions as \( q \), due to Algorithm (2.21) and

\[
\phi_{<x,a}(p) \sim \frac{\phi_{<x,a}(q)}{\text{gcd}(\phi_{<x,a}(q), \phi_{<x,a}(\phi_{<x,a}(q)))} = \frac{\phi_{<x,a}(q)}{\text{gcd}(\phi_{<x,a}(q), \phi_{<x,a}(p))} .
\]

In addition, in line 36,

\[
\phi_{<x,a}(r) \sim \frac{\phi_{<x,a}((S_T)_x)}{\text{gcd}(\phi_{<x,a}((S_T)_x), \phi_{<x,a}(p))} \Rightarrow \phi_{<x,a}(r \cdot p) \sim \text{lcm}(\phi_{<x,a}((S_T)_x), \phi_{<x,a}(p)) .
\]
This concludes the proof of the first loop invariant.

Now, we prove the second loop invariant. At the beginning, the loop invariant holds because $S_T' = \emptyset$ holds for the input system $S'$. Assume that the second loop invariant holds at the beginning of the main loop.

One easily checks that all steps in the algorithm allow only one polynomial $(S_T)_x$ in $S_T$ for each leader $x$, thus triangularity obviously holds.

We show that all polynomials added to $S_T$ have non-zero initial and are square-free. For $\text{Sol}(S_{<z}) = \emptyset$, the statement is trivially true. So, let $a \in \text{Sol}(S_{<z})$.

For the equation $p_\prec$ added as conditional gcd of $(S_T)_x$ and $q$ in line 15, it holds that $\phi_{<z,a}(p)$ is a divisor of $\phi_{<z,a}((S_T)_x)$. As $\phi_{<z,a}((S_T)_x)$ is square-free by assumption, so is $\phi_{<z,a}(p)$. The inequation added to $S$ in $\text{ResSplitGCD}$ is by Definition (2.13) the initial of $p_\prec$.

The equation $p_\prec$ inserted into $S_T$ in line 25 and the inequation $p_\prec$ inserted in line 38 are square-free due to Algorithm (2.21) and their initials are non-zero as $p$ is either identical to $q$, or it is a pseudo quotient of $q$ by $\text{PRS}_i(q, \frac{p}{q}, x)$ for some $i > 0$. On the one hand, if $p$ equals $q$, the call of $\text{InitSplit}$ for $q$ ensures a non-zero initial for $p$. On the other hand, the polynomial $\text{PRS}_i(q, \frac{p}{q}, x)$ has initial $\text{res}_i(q, \frac{p}{q}, x)$, which is added as an inequation by $\text{ResSplitSquareFree}$. This implies that the initial of the pseudo-quotient is also non-zero.

The equation $p_\prec$ that replaces the old equation $(S_T)_x$ in line 30 is the quotient of $(S_T)_x$ by an inequation. It is square-free, because $\phi_{<z,a}(p)$ is a divisor of $\phi_{<z,a}((S_T)_x)$, which is square-free by assumption. Again, $p$ is either identical to $(S_T)_x$ or a pseudo quotient of $(S_T)_x$ by $\text{PRS}_i((S_T)_x, q, x)$ for some $i > 0$ and, using the same arguments as in the last paragraph, the initial of $p$ does not vanish.

Finally, consider the inequation $(r \cdot p)_\prec$ added in line 36 as a least common multiple of $((S_T)_x)_\prec$ and $p_\prec$. The inequation $\phi_{<z,a}(p)$ is square-free and has non-vanishing initial for the same reasons as before. Due to $\phi_{<z,a}(r) \sim \frac{\phi_{<z,a}((S_T)_x)}{\gcd(\phi_{<z,a}((S_T)_x), \phi_{<z,a}(p))}$, the polynomials $\phi_{<z,a}(r)$ and $\phi_{<z,a}(p)$ have no common divisors. As $\phi_{<z,a}(r)$ divides $\phi_{<z,a}((S_T)_x)$, using the same arguments as before, $\phi_{<z,a}(r)$ is square-free and has a non-vanishing initial. This completes the proof of the second loop invariant.

It is obvious that a system $S$ with $S_Q = \emptyset$ for which these loop invariants hold is simple. Thus the algorithm returns the correct result if it terminates.

We now start showing termination. The system $S$ chosen from $P$ is treated in one of three ways: It is either discarded, added to $\text{Result}$, or replaced in $P$ by at least one new system. To show that $P$ is empty after finitely many iterations, we define an order on the systems and show that it is well-founded. Afterwards we prove termination by detailing that the algorithm produces descending chains of systems.

**Definition 2.27.** For transitive and asymmetric\(^7\) partial orders $<_i$ for $i = 1, \ldots, m$, we define the **composite order** $\prec := [<_1, \ldots, <_m]$ as follows: $a < b$ if and only if there exists $i \in \{1, \ldots, m\}$ such that $a <_i b$ and neither $a <_j b$ nor $b <_j a$ for $j < i$. The composite order is clearly transitive and asymmetric. An order $\prec$ is called **well-founded**, if each $\prec$-descending chain becomes stationary.

The following trivial statement will be used repeatedly:

**Remark 2.28.** If each $<_i$ is well-founded, then so is the composite ordering $\prec$, using the notation from Definition (2.27).

Now we define the orders and show their well-foundedness:

**Definition and Remark 2.29.** Define $\prec$ as the composite order $[<_1, <_2, <_3, <_4]$ of the four orders defined below. It is well-founded since the $<_i$ are.

\(^7\)A relation $\prec$ is asymmetric, if $S \prec S'$ implies $S' \not\prec S$ for all $S, S'$. Asymmetry implies irreflexivity.
1. For $i = 1, \ldots, n$ define $\prec_{1,i}$ by $S \prec_{1,i} S'$ if and only if $\mindeg((S_T)_{x_i}^-) < \mindeg((S'_T)_{x_i}^-)$, with $\mindeg((S_T)_{x_i}^-) := \infty$ if $(S_T)_{x_i}^-$ is empty. Define the composite order $\prec_1$ as $[\prec_{1,1}, \ldots, \prec_{1,n}]$. Since degrees can only decrease finitely many times, the orders $\prec_{1,\ast}$ are clearly well-founded and, thus, $\prec_1$ is.

2. Define the map $\mu$ from the set of all systems over $R$ to $\{1, x_1, \ldots, x_n, x_\infty\}$, where $\mu(S)$ is minimal such that there exists an equation $p \in (S_Q)_{\mu(S)}^-$ with $\text{Red}(S_T, p) \neq 0$, or $\mu(S) = x_\infty$ if no such equation exists. Then, $S \prec_2 S'$ if and only if $\mu(S) < \mu(S')$ with $1 < x_1$ and $x_1 < x_\infty$ for $i \in \{1, \ldots, n\}$. The ordering $\prec_2$ is well-founded since $< \infty$ is well-founded on the finite set $\{1, x_1, \ldots, x_n, x_\infty\}$.

3. $S \prec_3 S'$ if and only if there is $p_{\neq} \in R^\neq$ and a finite (possibly empty) set $L \subseteq R^\neq$ with $\deg(q) < \deg(p) \forall q \in L$ such that $S_Q \not\subseteq \{p_{\neq}\} = S_Q' \not\subseteq L$ holds. We show well-foundedness by induction on the highest appearing leader $x$ in $(S_Q)^{\neq}$. For $x = 1$ we can only make a system $S \prec_3$ smaller by removing one of the finitely many inequations in $(S_Q)^{\neq}$. Now assume that the statement is true for all indeterminates $y < x$. By the induction hypothesis we can only $\prec_3$-decrease $S$ finitely many times without changing $(S_Q)^{\neq}$. To further $\prec_3$-decrease $S$, we have to remove an inequation from $(S_Q)^{\neq}$. As $(S_Q)^{\neq}$ is finite, this process can only be repeated finitely many times until $(S_Q)^{\neq} = \emptyset$. Now, the highest appearing leader in $(S_Q)^{\neq}$ is smaller than $x$ and by the induction hypothesis, the statement is proved.

4. $S \prec_4 S'$ if and only if $|S_Q| < |S'_Q|$.

**Proof (Termination).** We will tacitly use the fact that reduction never makes polynomials bigger in the sense of Remark (2.7)(3).

We denote the system chosen from $P$ in line 3 by $\hat{S} \not\subseteq S$ and the system added to $P$ in line 43 by $S$. We prove that the systems $S, S_1, \ldots, S_7$ generated from $\hat{S}$ are $\prec_3$-smaller than $\hat{S}$. For $i = 1, \ldots, 4$ we will use the notation $S \not\subseteq S'$ if neither $S \prec_3 S'$ nor $S' \prec_3 S$ holds.

For $j = 1, \ldots, 7$, $((S_j)_T)^{\neq} = (\hat{S}_T)^{\neq}$ and thus $S_j \not\subseteq \hat{S}$. The properties of $\text{Select}$ in Definition (2.22) directly require, that there is no equation in $(S_Q)^{\neq}$ with a leader smaller than $x$. However, the equation added to the system $S_j$ returned from $\text{InitSplit}$ (2.12) is the initial of $q$, which has a leader smaller than $x$ and does not reduce to $0$ (cf. Remark (2.7)(2)). Furthermore, the equations added in one of the subalgorithms based on $\text{ResSplit}$ (2.18) have a leader smaller than $x$ and do not reduce to $0$. In each case $S_j \prec_2 \hat{S}$ is proved.

It remains to show $S \prec_4 \hat{S}$. If $q$ is reduced to $0_\infty$, then it is omitted from $S_Q$ and so $S \prec_4 \hat{S}$. As the system is otherwise unchanged, $S \not\subseteq \hat{S}, i = 1, 2, 3$ and therefore $S \not\subseteq \hat{S}$ holds. If $q$ is reduced to $c_{\neq}$ for some $c \not\in F \setminus\{0\}$, then $S \prec_3 \hat{S}$ and $S \not\subseteq \hat{S}, i = 1, 2$, since the only change was the removal of an inequation from $S_Q$. Otherwise, exactly one of the following cases will occur:

Lines 14-15 set $(S_T)_x$ to $p_{\neq}$ of smaller degree than $(\hat{S}_T)_x$ and 20-25 add $(S_T)_x$ as a new equation. In both cases we get $S \not\subseteq \hat{S}$.

In line 17, $S_T = \hat{S}_T$ implies $S \not\subseteq \hat{S}$. The polynomial $q$ is chosen according to $\text{Select}$ (cf. (2.22)(1)), which implies $(\hat{S}_Q)^{<x} = \emptyset$ and $(S_Q)^{<x} = \{\text{res}(S_T)_x, q, x\}$. Line 13 ensures $\text{Reduce}(\text{res}(S_T)_x, q, x), S) \neq 0$ and, thus, $S \prec_4 \hat{S}$ follows.

Consider lines 29-30. If the degree of $(S_T)_x$ is smaller than the degree of $(\hat{S}_T)_x$, then $S \prec_1 \hat{S}$. In case the degree doesn’t change, we have $S \not\subseteq \hat{S}$ and $(S_Q)^{=} = (\hat{S}_Q)^{=}$ guarantees $S \not\subseteq \hat{S}$. However, $q$ is removed from $S_Q$ and replaced by an inequation of smaller leader, which implies $S \prec_3 \hat{S}$.

In 31-39, obviously $S \not\subseteq \hat{S}, i = 1, 2$. As before, $q$ is removed from $S_Q$ and replaced by an inequation of smaller leader, which once more implies $S \prec_3 \hat{S}$. \qed
2.3. Notes to Applications of Simple Systems

In this subsection, we shortly present some examples where simple systems are necessary and any weaker decomposition into triangular systems is not sufficient.

The properties of simple systems (cf. Definition (2.2)) correspond exactly to the following fibration structure on the solution sets (cf. Plesken (2009a)). Let $S$ be a simple system and $\Pi_1 : T^i \rightarrow T^{i-1} : (a_1, \ldots, a_i) \mapsto (a_1, \ldots, a_{i-1})$. Furthermore, for any solution $a \in \mathcal{So}(S_{\leq x_1})$, let $s_{i,a} = \Pi_1^{-1}(\mathcal{B}(a))$. Then, if $S_{x_i}$ is an equation, $|s_{i,a}| = \text{mdeg}(S_{x_i})$ holds. If $S_{x_i}$ is an inequation, then $s_{i,a} = \mathcal{F} \setminus \tilde{s}_{i,a}$ with $|\tilde{s}_{i,a}| = \text{mdeg}(S_{x_i})$. If $S_{x_i}$ is empty, then $s_{i,a} = \mathcal{F}$. The cardinalities of $s_{i,a}$ or $\tilde{s}_{i,a}$ are constant for each $i$, i.e. independent of the choice of the solution $a \in \mathcal{So}(S_{\leq x_1})$ (cf. Remark (2.3)). We can examine solution sets of arbitrary systems by decomposing them disjointly into simple systems. Further analysis of this fibration structure, especially in the context of algebraic varieties, is a topic of future research.

We already saw such a fibration structure in Example (2.1). In this case, other triangular decompositions like a decomposition into regular chains would have only resulted in a single system consisting of the polynomial $p$ from the input.

A special case occurs when all polynomials in the input and output can be factored into linear polynomials. If we compute the counting polynomial as introduced by Plesken (2009a) (which requires the disjointness of the decomposition and the fibration structure), we can substitute the cardinality of a finite field $F$ (of sufficiently large characteristic) into the counting polynomial of a THOMAS decomposition computed over $\mathbb{Q}$. This yields the exact number of distinct solutions over $F$. For example, the counting polynomial of a THOMAS decomposition of $\{\det(M) \neq 0\}$ for a generic $n \times n$ matrix $M = (x_{ij})_{1 \leq i,j \leq n}$ yields the well-known formula for the cardinality of $\text{GL}_n(F)$ for any finite field $F$. Furthermore, we can automatically reproduce the results in (Plesken, 1982, Ex. V.4), where pairs of matrices $(A, B)$ with given ranks of $A$, $B$, and $A + B$ are counted.

Plesken (2009b) gave another example concerning the GAUSS-BRUHAT-decomposition and the LU-decomposition. The cells of these decompositions of $M$ as above can be identified with certain simple systems in the THOMAS decomposition of $\{\det(M) \neq 0\}$ for suitable rankings on the $x_{ij}$.

We clearly see that simple systems are necessary for these applications to expose the aforementioned fibration structure and count solutions. A disjoint decomposition into triangular systems with weaker properties does not suffice.

3. Differential Thomas Decomposition

The differential THOMAS decomposition is concerned with manipulations of polynomial differential equations and inequations. The basic idea for our construction of this decomposition is twofold. On the one hand, a combinatorial calculus developed by JANET finds unique reducers and all integrability conditions by completing systems to involutions. On the other hand, the algebraic THOMAS decomposition makes the necessary splits for regularity of initials and ensures disjointness of the solution sets.

Initially, we recall some basic definitions from differential algebra. Then, we summarize the JANET division and its relevance. Its combinatorics lead us to substitute the algebraic algorithm InsertEquation by its differential analog. Afterwards, we review a differential generalization of the algebraic reduction algorithm and present the algorithm Reduce utilized for differential reduction. Replacing the insertion and reduction from the previous section with these differential counterparts yields the differential THOMAS decomposition algorithm.

3.1. Preliminaries from Differential Algebra

Let $\Delta = \{\partial_1, \ldots, \partial_n\}$ be a non-empty set of derivations and $F$ be a $\Delta$-ring. This means any $\partial_i \in \Delta$ is a linear operator $\partial_i : F \rightarrow F$ which satisfies the LEIBNIZ rule. Given a differential indeterminate $u$, the polynomial $\Delta$-ring $F\{u\} := F[ u_i | i \in \mathbb{Z}_{\geq 0}^n ]$ is defined as the polynomial ring infinitely generated by the algebraically independent set $\{ u_i | i \in \mathbb{Z}_{\geq 0}^n \}$. The operation of $\partial_i \in \Delta$ on $\{ u \}_{\Delta}$ is defined by $\partial_i u_i = u_{i+e_i}$ and this operation extends linearly and via the LEIBNIZ rule to $F\{u\}$. Let $U = \{ u^{(1)}, \ldots, u^{(m)} \}$ be a set of differential indeterminates.
The multivariate polynomial $\Delta$-ring is given by $F\{U\} := F\{u^{(1)}\} \ldots \{u^{(m)}\}$. Its generators, the elements of $\langle U \rangle_\Delta := \{u^{(j)}_i \mid i \in \mathbb{Z}_{\geq 0}, j \in \{1, \ldots, m\}\}$, are called differential variables. From now on let $F$ be a computable $\Delta$-field of characteristic zero.

The differential structure of $F$ uniquely extends to the differential structure of its algebraic closure $\overline{F}$ (Kolchin, 1973, §II.2, Lemma 1). Let $E := \bigoplus_{j=1}^m \overline{F}[[z_1, \ldots, z_n]]$ where $\overline{F}[[z_1, \ldots, z_n]]$ denotes the ring of formal power series in $z_1, \ldots, z_n$. Then $E$ is isomorphic to $\overline{F}^{\langle U \rangle_\Delta}$ via

$$
\alpha : \bigoplus_{j=1}^m \overline{F}[[z_1, \ldots, z_n]] \to \overline{F}^{\langle U \rangle_\Delta} : \left( \sum_{i \in \mathbb{Z}_{\geq 0}} a^{(1)}_i z^i, \ldots, \sum_{i \in \mathbb{Z}_{\geq 0}} a^{(m)}_i z^i \right) \mapsto \left( u^{(1)}_i \mapsto a^{(1)}_i, \ldots, u^{(m)}_i \mapsto a^{(m)}_i \right)
$$

where $z^i := z_1^{i_1} \cdots z_n^{i_n}$ and $i! := i_1! \cdots i_n!$.

We define solutions in $E$, consistent with the algebraic case: For $e \in E$, let

$$
\phi_e : F\{U\} \to \overline{F} : u^{(j)}_i \mapsto \alpha(e)(u^{(j)}_i)
$$

be the $F$-algebra homomorphism evaluating the differential variables at $e$. A differential equation or inequation for $m$ functions $U = \{u^{(1)}, \ldots, u^{(m)}\}$ in $n$ indeterminates is an element $p \in F\{U\}$, written $p_\Delta$ or $p_\nabla$, respectively. A solution of $p_\Delta$ or $p_\nabla$ is an element $e \in E$ with $\phi_e(\langle p \rangle_\Delta) = \{0\}$ or $\phi_e(\langle p \rangle_\nabla) \neq \{0\}$, respectively. Here, $\langle p \rangle_\Delta$ denotes the differential ideal in $F\{U\}$ generated by $p$.

Furthermore, $e \in E$ is called a solution of a set $P$ of equations and inequations, if it is a solution of each element in $P$. The set of solutions of $P$ is denoted by $\mathfrak{S}d(P) := \mathfrak{S}d_\nabla(P) \subseteq E$.

In differential algebra one usually considers solutions in a universal $\Delta$-field, while we consider power series solutions. As the universal differential field we can take the universal closure $\overline{F}$ of $\overline{F}$. There is a strong link between these two concepts. On the one hand, Seidenberg (1958, 1969) has shown that every finitely differentially generated differential field is differentially isomorphic to a differential field of meromorphic functions in $n$ variables. On the other hand, $\overline{F}[[z_1, \ldots, z_n]] \to \overline{F}((z_1, \ldots, z_n)) \to \overline{F}$. Here, the first map is the natural embedding into the quotient field and the second is an embedding given by the definition of the universal $\Delta$-field (Kolchin, 1973, §II.2 and §III.7), as $\overline{F}((z_1, \ldots, z_n))$ is a finitely generated $\Delta$-field extension of $\overline{F}$. Thus, any power series solution can be considered as a solution in the universal differential field. A finite set of equations and inequations is called a (differential) system over $F\{U\}$. We will be using the same notation for systems as in the algebraic Thom decomposition introduced in §2.1 and §2.2, in particular a system $S$ is represented by a pair $(S_T, S_Q)$. However, the candidate simple system $S_T$ will also reflect a differential structure based on the combinatorics from the following section.

3.2. Janet Division

In this subsection we will focus on a combinatorial approach called JANET division (cf. Gerdt and Blinkov (1998a)). It manages the infinite set of differential variables and guarantees inclusion of all integrability conditions in a differential system. For this purpose, it partitions the set of differential variables into “free” variables and finitely many “cones” of dependent variables. We present an algorithm for inserting new equations into an existing set of equations and adjusting this cone decomposition accordingly. An overview of modern development on JANET division can be found in Gerdt (2005) and Seiler (2010) and the original ideas were formulated by Janet (1929).

A (differential) ranking $<$ is defined as a total order on the differential variables and 1 with $1 < u \forall u \in U$, such that

1. $u < \partial_j u$ and
2. $u < v$ implies $\partial_j u < \partial_j v$

for all $u, v \in \langle U \rangle_\Delta, \partial_j \in \Delta$. From now on let $<$ be an arbitrary and fixed differential ranking. For any finite set of differential variables, a differential ranking induces a ranking as defined for the
algebraic case in §2.1. Thereby, in accordance to the algebraic part, define the largest differential variable \( \text{ld}(p) \) appearing in a differential polynomial \( p \in F\{U\} \) as **leader**, which is set to 1 for \( p \in F \). Furthermore, define \( \text{mdeg}(p) \) and \( \text{init}(p) \) as the degree in the leader and the coefficient of \( \text{ld}(p)^{\text{mdeg}(p)} \), respectively.

**Example 3.1.** Consider two derivations \( \Delta = \{ \partial_x, \partial_t \} \) and one differential indeterminate \( u \).

In this setting, any partial differential equation with constant coefficients in one dependent variable and two independent variables can be represented as a differential polynomial in \( \mathbb{C}\{u\} \).

The ranking \( < \) is defined by \( u_{i_1,i_2} < u_{j_1,j_2} \) if and only if either \( i_1 + i_2 < j_1 + j_2 \) or \( i_1 + i_2 = j_1 + j_2 \) and \( i_2 < j_2 \) holds. Thus, the smallest differential variables are: \( u_{0,0} < u_{0,1} < u_{1,0} < u_{2,0} < u_{1,1} < u_{0,2} < u_{3,0} \). When considering the set of differential variables as a grid in the first quadrant of a plane, the picture on the left illustrates this ranking.

Consider \((u_{0,1} + u_{0,0}u_{1,0})= \) representing the inviscid BURGER’s equation \( \partial_t u + u \partial_x u = 0 \). As in the algebraic part, we indicate an equation in the picture by attaching it to its leader. However, contrary to the algebraic part, a differential equation does not only affect its leader, but also the derivatives of its leader. This is because property 2 of a differential ranking implies \( \partial \text{ld}(p) = \text{ld}(\partial p) \) \( \forall \partial \in \Delta, p \in F\{U\} \). For example \( \partial_t(u_{0,1} + u_{0,0}u_{1,0}) = u_{0,2} + u_{0,1}u_{1,0} + u_{0,0}u_{1,1} \). In the diagram we illustrate this by drawing a cone with apex \( u_{0,1} \).

Assume that we are only interested in solutions of the inviscid BURGER’s equation which are linear in \( x \). So, we add the second equation \((u_{2,0})= \) to our system. This second equation also affects the derivatives of its leader. In particular, \((u_{0,1} + u_{0,0}u_{1,0})= \) and \((u_{2,0})= \) both affect the differential variable \( u_{2,0} \) and its derivatives. This contradicts the triangularity of the system. According to the involutive approach as suggested by JANET, we don’t allow certain equations to be derived by certain partial derivations. In this example, we allow \((u_{2,0})= \) to be derived only by \( \partial_x \). In the diagram we illustrate this by drawing a (degenerate) cone with apex \( u_{2,0} \) in direction of \( \partial_x \). Thus, the differential consequence \((\partial_t u_{2,0})= \) is not yet considered and, so, we have to add it as a separate equation for further treatment.

A set \( W \) of differential variables is **closed** under the action of \( \Delta' \subseteq \Delta \) if \( \partial \in \Delta' \) and \( w \in W \). The smallest set containing a differential variable \( w \), which is closed under \( \Delta' \), is called a **cone** and denoted by \( \langle w \rangle_{\Delta'} \). In this case, we call the elements of \( \Delta' \) **reductive derivations**\(^8\). The \( \Delta' \)-closed set generated by a set \( W \) of differential variables is defined as

\[
\langle W \rangle_{\Delta'} := \bigcap_{W_i \supseteq W, W_i \Delta' \text{-closed}} W_i \subseteq \langle U \rangle_{\Delta}. 
\]

For a finite set \( W = \{ w_1, \ldots, w_r \} \), the JANET **division** algorithmically assigns reductive derivations to the elements of \( W \) such that the cones generated by the \( w \in W \) are disjoint (cf. Gerdt et al. (2001) for a fast algorithm). We call these derivations JANET-reductive. The derivation \( \partial_i \in \Delta \) is assigned to the cone generated by \( w = u_i^{(j)} \in W \) as reductive derivation, if and only if

\[
i_k = \max \left\{ i_l' \mid u_i^{(j)} \in W, i_k' = i_k \text{ for all } 1 \leq k < l \right\}
\]

\(^8\) In Gerdt (1999) and (Seiler, 2010, Chap. 7) the reductive derivations are called multiplicatice variables and in Bächler et al. (2010) they are called admissible derivations.
holds (Gerdt, 2005, Ex. 3.1). We remark that $j$ is fixed in this definition, i.e., when constructing cones we only take into account other differential variables belonging to the same differential indeterminate. Furthermore, the assignment of reductive derivations to $w \in W$ in general depends on the whole set $W$. The reductive derivations assigned to $w$ are denoted by $\Delta_w(w) \subseteq \Delta$ and we call the cone $\langle w \rangle_{\Delta_w(w)}$ the JANET cone of $w$ with respect to $W$. This construction ensures disjointness of cones but not necessarily that the union of cones equals $\langle W \rangle_\Delta$. The problem is circumvented by enriching $W$ to its JANET completion $\bar{W} \supseteq W$. This completion $\bar{W}$ is successively created by adding any

$$\bar{w} = \partial_i w_j \not\in \bigcup_{w \in \bar{W}} \langle w \rangle_{\Delta_{\bar{w}}(w)}$$

to $\bar{W}$, where $w_j \in \bar{W}$ and $\partial_i \in \Delta \setminus \Delta_{\bar{w}}(w_j)$. This leads to the disjoint JANET decomposition

$$\langle W \rangle_\Delta = \bigcup_{w \in \bar{W}} \langle w \rangle_{\Delta_{\bar{w}}(w)}$$

that algorithmically separates a $\Delta$-closed set $\langle W \rangle_\Delta$ into finitely many cones $\langle w \rangle_{\Delta_{\bar{w}}(w)}$. For details see (Gerdt, 2005, Def. 3.4) and (Gerdt and Blinkov, 1998a, Cor. 4.11).

We extend the JANET decomposition from differential variables to differential polynomials according to their leaders. To be precise, $\Delta_T(q) := \Delta_{ld(T)}(ld(q))$ for finite $T \subset F\{U\}$ and $q \in T$. We call a derivative of an equation by a finite (possibly empty) sequence of derivations a prolongation. If all these derivations are reductive, the derivative is called reductive prolongation of $q$ with respect to $T$. Otherwise it is called non-reductive prolongation.

A differential polynomial $p \in F\{U\}$ is called reducible modulo $q \in F\{U\}$, if there exists $i \in \mathbb{Z}_{\geq 0}^n$ such that $\partial_1^{i_1} \cdots \partial_n^{i_n} ld(q) = ld(\partial_1^{i_1} \cdots \partial_n^{i_n} q) = ld(p)$ and $mdeg(\partial_1^{i_1} \cdots \partial_n^{i_n} q) \leq \operatorname{mdeg}(p)$. For $i \neq (0, \ldots, 0)$ the condition on the main degree always holds. We now restrict ourselves to reductive prolongations: For a finite set $T \subset F\{U\}$, we call a differential polynomial $p \in F\{U\}$ JANET-reducible modulo $q \in T$ w.r.t. $T$, if $p$ is reducible modulo $q$ and $\partial_1^{i_1} \cdots \partial_n^{i_n} q$ is a reductive prolongation of $q$ w.r.t. $T$, with $i \in \mathbb{Z}_{\geq 0}^n$ from the reducibility conditions. We also say that $p$ is JANET-reducible modulo $T$ if there is a $q \in T$ such that $p$ is JANET-reducible modulo $q$ w.r.t. $T$.

A set of differential variables $T \subset \langle U \rangle_\Delta$ is called minimal, if for any set $S \subset \langle U \rangle_\Delta$ with

$$\bigcup_{t \in T} \langle t \rangle_{\Delta_T(t)} = \bigcup_{s \in S} \langle s \rangle_{\Delta_S(s)}$$

the condition $T \subseteq S$ holds (Gerdt and Blinkov, 1998b, Def. 4.2). We call a set of differential polynomials minimal, if the corresponding set of leaders is minimal.

At each step of the algorithm we assign reductive derivations to the equations in $(S_T)^\circ$. When an equation $p$ is not reducible modulo $(S_T)^\circ$, it is added to $(S_T)^\circ$. Then, we remove all polynomials from $S_T$ that have a leader which is derivative of $ld(p)$. This will later ensure minimality. In addition, when adding a new equation to $(S_T)^\circ$, all non-reductive prolongations are put into the queue. This is formalized in the following algorithm.

**Algorithm 3.2 (InsertEquation).**

*Input: A system $S'$ and a polynomial $p_\circ \in F\{U\}$ not reducible modulo $(S_T')^\circ$.*

*Output: A system $S$, where $(S_T)^\circ \subseteq (S_T)^\circ \cup \{p_\circ\}$ is maximal satisfying

$$(ld(S_T) \setminus \{ld(p)\}) \cap (ld(p))_\Delta = \emptyset,$$

$$S_Q = S_Q' \cup (S_T' \setminus S_T) \cup \{(\partial_i q_\circ \mid q \in (S_T)^\circ, \partial_i \not\in \Delta_{(S_T)^\circ}(q)\}.$$*

*Algorithm:*

1. $S \leftarrow S'$
2. $S_T \leftarrow S_T \cup \{p_\circ\}$
3: for q ∈ ST \ {p} do
4: if ld(q) ∈ ⟨ld(p)⟩Δ then
5: ST ← ST ∪ {q}
6: S ← ST \ {q}
7: end if
8: end for
9: Reassign reductive derivations to (ST)∗
10: S ← SQ ∪ \{∂i,q) = 0 \{q ∈ (ST)∗, ∂i ∈ Δ((ST)∗)(q)\} 
11: return S

Correctness and termination are obvious. We remark that a non-reductive prolongation might be added to ST several times. An implementation should remember which prolongations have been added before to avoid redundant computations.

### 3.3. Differential Simple Systems

In this subsection, we extend the algebraic reduction algorithm to its differential counterpart. Finally, we can define differential simple systems at the end of this subsection.

The JANET partition of the dependent differential variables into cones provides a mechanism to find the unique reductor for the differential reduction in a fast way (cf. Gerdt et al. (2001)). We prolong this reductor and afterwards apply a pseudo-reduction algorithm.

For a valid pseudo-reduction, we need to ensure that initials (and initials of the prolongations) of equations are non-zero. Let \( r \in F\{U\} \) with \( x = \text{ld}(r) \) and define the \textit{separant} \( \text{sep}(r) := \frac{r}{\text{ld}(r)} \).

One easily checks that the initial of any non-trivial prolongation of \( r \) is \( \text{sep}(r) \) and the separant of any square-free equation \( r \) is non-zero (cf. (Kolchin, 1973, §I.8, Lemma 5) or (Hubert, 2003b, §3.1)). So, by making sure that the equations have non-vanishing initials and are square-free, as in the algebraic case, we ensure that we can reduce modulo all prolongations of \( r \). This provides the correctness of the following reduction algorithm.

**Algorithm 3.3 (Reduce).**

Input: A differential system \( S \) and a polynomial \( p \in F\{U\} \).

Output: A polynomial \( q \) that is not JANET-reducible modulo \( ST \) with \( φ_e(p) = 0 \) if and only if \( φ_e(q) = 0 \) for each \( e \in \text{Sol}(S) \).

Algorithm:

1: \( x := \text{ld}(p) \)
2: while exists \( q = (ST)∗ \) and \( i \in \mathbb{Z}_{>0}^{n} \) with \( i_j = 0 \) for \( ∂_i \notin Δ((ST)∗)(q) \) such that \( ∂_1^{i_1} \cdots ∂_n^{i_n} \text{ld}(q) = \text{ld}(p) \) and \( \text{mdeg}(∂_1^{i_1} \cdots ∂_n^{i_n} p) \geq \text{mdeg}(q) \) hold do
3: \( p := \text{prem}(p,∂_1^{i_1} \cdots ∂_n^{i_n} q, x) \)
4: \( x := \text{ld}(p) \)
5: end while
6: if Reduce(\( S, \text{init}(p) \)) = 0 then
7: return Reduce(\( S, p - \text{init}(p)x^{\text{mdeg}(p)} \))
8: else
9: return \( p \)
10: end if

A polynomial \( p \in F\{U\} \) reduces to \( q \) modulo \( ST \) if \( \text{Reduce}(S, p) = q \). A polynomial \( p \in F\{U\} \) is called \textbf{reduced} modulo \( ST \) if it reduces to itself. The properties of the algebraic reduction algorithm from Remark (2.7) also apply for this reduction algorithm.

---

9 In differential algebra, one usually distinguishes a (full) differential reduction as used here and a partial (differential) reduction. Partial reduction only employs proper derivations of equations for reduction (cf. (Kolchin, 1973, §I.9) or (Hubert, 2003b, §3.2)). This is useful for separation of differential and algebraic parts of the algorithm and for the use of Rosenfeld’s Lemma (cf. Rosenfeld (1959)), which is the theoretical basis for the Rosenfeld-Gröbner algorithm (cf. Boulier et al. (2009, 1995); Hubert (2003b)).

10 There is a fine difference between not being reducible and being reduced. In the case of not being reducible the initial of a polynomial can still reduce to zero and iteratively the entire polynomial.
Termination of the reduction algorithm is provided by Dickson’s Lemma (cf. (Cox et al., 1992, Chap. 2, Thm. 5) or (Kolchin, 1973, §0.17, Lemma 15)), which states that the ranking $<$ is well-founded on the set of leaders, i.e., a strictly $<$-descending chain of leaders is finite.

**Example 3.4.** We continue Example (3.1) and take care of the differential consequence $(u_{2,1})_=$.

We reduce $(u_{2,1})_=$ modulo the system $S$ with

$$S_T := \left\{ p_1 := (u_{0,1} + u_{0,0}u_{1,0})_=, p_2 := (u_{2,0})_= \right\}.$$  

First, we observe, that $\text{ld}(u_{2,1}) = u_{2,1}$ is in the cone generated by $\text{ld}(p_1)$ and $\text{ld}(\partial_{x}^2 p_1) = \text{ld}(u_{2,1})$. Thus, we reduce $(u_{2,1})_=$ modulo $\partial_{x}^2 p_1$ and the pseudo reduction yields $u_{0,0}u_{3,0} + 3u_{1,0}u_{2,0}$. Second, we reduce $u_{0,0}u_{3,0} + 3u_{1,0}u_{2,0}$ modulo $\partial_{x} p_2$, because $u_{3,0}$ lies in the cone generated by $(u_{2,0})_=$. This results in $3u_{1,0}u_{2,0}$ and a third reduction step modulo $p_2$ produces zero. As a result, the only differential consequence is already implied by the system. In this desirable situation, there are no further integrability conditions, which motivates the definition of involutivity below.

Now, we define differential simple systems. We demand algebraic simplicity, involutivity of differential equations as seen in the previous Example (3.4), and some minimality conditions.

**Definition 3.5 (Differential Simple Systems).** A differential system $S$ is (Janet-) involutive, if all non-reductive prolongations of $(S_T)^-$ reduce to zero modulo $(S_T)^-$. A system $S$ is called differentially simple or simple, if

1. $S$ is algebraically simple (in the finitely many differential variables that appear in it),
2. $S$ is involutive,
3. $S^-$ is minimal,
4. no inequation in $S^-$ is reducible modulo $S^-$.  

A disjoint decomposition of a system into differentially simple subsystems is called (differential) Thomas decomposition.

As in the algebraic case, every simple system has a solution in $E$.

**3.4. Differential Decomposition Algorithm**

The differential Thomas decomposition algorithm is a modification of the algebraic Thomas decomposition algorithm. We have already introduced the new algorithms InsertEquation (3.2) for adding new equations into the systems and Reduce (3.3) for reduction, that can replace their counterparts in the algebraic algorithm. This subsection provides the necessary correctness and termination proofs for this modified algorithm. It then demonstrates this algorithm with examples.

**Algorithm 3.6 (DifferentialDecompose).**

*Input:* A differential system $S'$ with $(S')_T = \emptyset$.

*Output:* A differential Thomas decomposition of $S'$.

*Algorithm:* The algorithm is obtained by replacing the two subalgorithms InsertEquation and Reduce in Algorithm (2.25) with their differential counterparts (3.2) and (3.3), respectively.

**Proof (Correctness).** The correctness proof of the algebraic decomposition Algorithm (2.25) also holds verbatim for the differential case. Therefore, we do not need to show that the output is algebraically simple. We will prove three loop invariants for any system $S \in P \cup Result$: 

22
1. \((S_T)^=\) is minimal.

2. No inequation in \((S_T)^=\) is JANET-reducible modulo \(S_T\).

3. Let \(r\) be any non-reductive prolongation of \((S_T)^=\). Then \(r\) reduces to zero by using both conventional differential reductions\(^{11}\) of \((S_Q)^=\) and reductions modulo reductive prolongations of \((S_T)^=\).

The first loop invariant is a purely combinatorial matter, which is proved by Gerdt (2002) for an algorithm using exactly the same combinatorial approach.

Proving the second loop invariant is equally simple. On the one hand, a newly added inequation \(q\) in \(S_T\) is not JANET-reducible modulo \((S_T)^=\), since algorithm Reduce (3.3) is applied to it before insertion. On the other hand, algorithm InsertEquation (3.2) removes all inequations from \(S_T\) which are divisible by a newly added equation and places them into \(S_Q\).

The third loop invariant clearly holds at the beginning of the algorithm, because \(S_T\) is empty.

We claim that reduction of an equation \(q_e \in S_Q\) by \((S_T)^=\) in line 8 of Algorithm (2.25) does not affect the loop invariant, i.e. any non-reductive prolongation \(r\) reducing to zero beforehand reduces to zero afterwards. We prove this claim by performing a single reduction step on \(q\), which generalizes by an easy induction. Let \(q' := \text{rem}(q, p, x) = m \cdot q - \text{pquo}(q, p, x) \cdot p\) be a pseudo remainder identity (see (1) on page 5) reducing \(q\) to \(q'\) modulo \(p\). Then a pseudo remainder identity \(\text{rem}(r, q, x) = m' \cdot r - \text{pquo}(r, q, x) \cdot q\) describing a reduction of \(r\) modulo \(q\) might simply be rewritten as the iterated identity

\[
\text{rem}(\text{rem}(r, q, x), q', x) = m \cdot \text{rem}(r, q, x) \cdot q' - \text{pquo}(r, q, x) \cdot \text{pquo}(q, p, x) \cdot p.
\]

Using the LEIBNIZ rule the same holds for reduction modulo partial derivatives of \(q\). This holds especially for an equation \(q_e \in S_Q\) reducing to 0 modulo \((S_T)^=\) in line 8, which can be removed from \(S_Q\) without violating the loop invariant.

Now, we consider line 25, where InsertEquation inserts the square-free part \(p_e\) of \(q_e\) into \(S_T\) and show that this does not violate the third loop invariant. First, the non-reductive prolongations in \(\{(\partial_i r) = r \in (S_T)^=\mid \partial_i \notin \Delta((S_T)^=\})\}\) are added to \(S_Q\) as equations. Thus, any of these reduce to 0 modulo \((S_Q)^=\). Second, moving equations from \(S_T\) back into \(S_Q\) in InsertEquation does not change the loop invariant either, because their reductive prolongations can still be used for reduction afterwards. Third, every non-reductive prolongation that reduced to zero using \(q_e \in (S_Q)^=\) still reduces to zero after InsertEquation. This holds for two reasons. On the one hand, everything that reduces to zero modulo \(q_e\), also reduces to zero modulo \(p_e\). Write \(m \cdot q = p \cdot q_1\) with \(\text{ld}(m) < x\) and \(\phi_a(m) \neq 0; \forall a \in \text{Sol}(S_{<\text{ld}(q)})\). Then \(p\) algebraically pseudo-reduces \(q\) to zero. Any derivative \(\partial q\) of \(q\) is reduced to zero modulo \(p_e\) and \((\partial p)_e\), since \(\partial(m \cdot q) = (\partial p) \cdot q_1 + p \cdot (\partial q_1)\) for any \(\partial \in \Delta\). Inductively, the same holds for repeated derivatives of \(q_e\). Therefore, \(p_e\) implies all constraints given by \(q_e\). On the other hand, all reduction steps modulo \(p_e\) are either Janet-reductions modulo \(p_e\) w.r.t. \(S_T\) or differential reductions modulo non-reductive prolongations of \(p_e\). The latter equations have been added to \(S_Q\).

When computing the gcd of two equations in line 14, the gcd of \(q\) and \((S_T)_x\) will be inserted into \(S_T\) and reduces everything to zero that both \(q\) and \((S_T)_x\) did. As above, the non-reductive prolongations are covered by inserting them into \(S_Q\) and the reductive prolongations are implied.

Dividing an equation \((S_T)_x\) by an inequation \(q_\neq\) in lines 29 and 30 also influences \((S_T)^=\).

This proves the third loop invariant. When the algorithm terminates, \(S_Q\) is empty and thus all non-reductive prolongations from \((S_T)^=\) JANET-reduce to zero modulo \((S_T)^=\). The system is therefore involutive.

\(^{11}\)i.e. modulo any prolongation
Furthermore, the first loop invariant implies minimality and the second loop invariant implies that no inequation is reducible by an equation, since for an involutive set reducibility is equivalent to JANET-reducibility.

□

Our main tool for proving the termination of the algorithm is using six orders on differential systems. These are similar to the four orders used to show the termination of the algebraic decomposition algorithm. We use Dickson’s lemma as main tool to show the well-foundedness of these orders.

**Definition and Remark 3.7.** Define the orders \( \prec_{1a}, \prec_{1b}, \prec_{1c}, \prec_2, \prec_3, \) and \( \prec_4 \) as follows.

\( \prec_{1a} \): For \( V \subseteq \langle U \rangle_{\Delta} \) there is a unique minimal set \( \nu(V) \subseteq V \) with \( V \subseteq \langle \nu(V) \rangle_{\Delta} \) (Coz et al., 1992, Chap. 2, §4, exercise 7 and 8), called **canonical differential generators** of \( V \). For a system \( S \), define \( \nu(S) = \nu(\text{ld}((S_T)^{\infty})) \). For systems \( S, S' \), we define \( S \prec_{1a} S' \) if and only if \( \min_<(\nu(S) \setminus \nu(S')) < \min_<(\nu(S') \setminus \nu(S)) \). An empty set is assumed to have \( x_\infty \) as minimum, which is \( \prec \)-larger than all differential variables. By Dickson’s lemma, \( \prec_{1a} \) is well-founded.

\( \prec_{1b} \): For systems \( S, S' \), define \( S \prec_{1b} S' \) if and only if \( S \not\prec_{1a} S' \) and \( \min_<(\text{ld}((S_T)^{\infty}) \setminus \text{ld}((S'_T)^{\infty})) < \min_<(\text{ld}((S'_T)^{\infty}) \setminus \text{ld}((S_T)^{\infty})) \). Minimality of \( (S_T)^{\infty} \) at each step of the algorithm and the constructivity property of the JANET division (Gerdt and Blinkov, 1998a, Prop. 4.13) imply well-foundedness of \( \prec_{1b} \) (Gerdt and Blinkov, 1998a, Thm. 4.14).

\( \prec_{1c} \): For systems \( S \) and \( S' \) with \( S \not\prec_{1a} S' \) and \( \not\prec_{1b} S \), both \( (S_T)^{\infty} \) and \( (S'_T)^{\infty} \) have the same leaders \( x_1, \ldots, x_i \). Define \( S \prec_{1c,x_i} S' \) if and only if \( \text{mdet}((S_T)^{\infty}_{x_i}) < \text{mdet}((S'_T)^{\infty}_{x_i}) \). This order is clearly well-founded. For these systems define \( S \prec_{1c} S' \) as \( \prec_{1c,x_1}, \ldots, \prec_{1c,x_i} \), which is again well-founded as a composite order.

\( \prec_2 \): This is defined identical to the algebraic \( \prec_2 \). We remark, that in this case the set of possible leaders is \( \{1\} \cup \langle U \rangle_{\Delta} \). To show well-foundedness of the differential ordering \( \prec_2 \) we use that \( \prec \) is well-founded on the set of leaders as implied by Dickson’s lemma. This way, \( \prec \) is extended to a well-founded ordering on \( \{1, x_\infty\} \cup \langle U \rangle_{\Delta} \) with \( 1 < y \) and \( y < x_\infty \) for all \( y \in \langle U \rangle_{\Delta} \).

\( \prec_3 \): This is verbatim the same condition and proof of well-foundedness as in the algebraic case. However, in the latter proof, we do a NOETHERIAN induction (Bourbaki, 1968, III.6.5, Prop. 7) instead of an ordinary induction.

\( \prec_4 \): This is identical to the algebraic case.

**Remark (2.28)** provides the well-foundedness of the composite order \( \prec := [\prec_{1a}, \prec_{1b}, \prec_{1c}, \prec_2, \prec_3, \prec_4] \).

**Proof (Termination).** We prove termination the same way as in the algebraic case. All arguments where systems get \( \prec_2, \prec_3, \) or \( \prec_4 \) smaller apply verbatim here.

In the algebraic case a system \( \prec_{1a} \)-decreases if and only if either an equation is added to \( S_T \) or the degree of an existing equation in \( S_T \) is decreased. We adapt this argument to the differential case: On the one hand, inserting a new equation with a leader that is not yet present in \( \text{ld}((S_T)^{\infty}) \) decreases either \( \prec_{1a} \) or \( \prec_{1b} \). On the other hand, if an existing equation in \( (S_T)^{\infty} \) is replaced by one with the same leader and lower degree, the system \( \prec_{1c} \)-decreases.

Thus, like in the algebraic termination proof, we have a strictly decreasing chain of systems and, thus, termination is proved. □

In the following examples, we use jet notation for differential polynomials, e.g., \( u_{x,x,y} := u_{2,1} \) in the case \( \Delta = \{\partial_x, \partial_y\} \) and \( U = \{u\} \).

We give an example taken from (Buium and Cassidy, 1999, pp. 597-600):
Example 3.8 (Cole-Hopf Transformation). For $F := \mathbb{R}(x, t)$, $\Delta = \{ \frac{\partial}{\partial x}, \frac{\partial}{\partial t} \}$, and $U = \{ \eta, \zeta \}$ consider the heat equation $h = (\eta t + \eta xx)$ and BURGER’s equation $b = (\zeta t + \zeta xx + 2\zeta x \cdot \zeta) = 0$.

First, we claim that any power series solution for the heat equation with a non-zero constant term can be transformed to a solution of BURGER’s equation using the COLE-HOPF transformation $\lambda : \eta \mapsto \frac{\eta}{t}$. A differential THOMAS decomposition for an orderly ranking with $\zeta > \eta$ of

\[ \{ h = (\eta \cdot \zeta - \eta x) = \eta, \zeta \} \]

with $f$ is simple, for any solution $\Delta$ in the $F$-ring. Due to the ranking, the first two equations in ($\lambda$) generate $\{ b = (\eta \cdot \zeta - \eta x) = \eta, \zeta \}$. A differential THOMAS decomposition for an orderly ranking with $\zeta > \eta$ of

\[ \{ h = (\eta \cdot \zeta - \eta x) = \eta, \zeta \} \]

consists of the single system

\[ S = \{ (\eta t - \eta \cdot \zeta) = (\eta \cdot \zeta_x + \eta t + \eta \cdot \zeta^2) = \eta, \zeta \} \]

and one checks that $\text{Reduce}(S, b) = 0$ holds. This implies that $\lambda$ maps any non-zero solution of the heat equation to a solution of BURGER’s equation.

In addition we claim that $\lambda$ is surjective. For the proof we choose an elimination ranking (cf. [Hubert, 2003b, §8.1] or [Boudier, 2007]) with $\eta \gg \zeta$, i.e., $\eta_i > \zeta_j$ for all $i, j \in \mathbb{Z}_{>0}$. We compute a differential THOMAS decomposition of $\{ h = (\eta t - \eta \cdot \zeta) = \eta, \zeta \}$. It consists of the single system

\[ S = \{ (\eta t - \eta \cdot \zeta) = (\eta \cdot \zeta_x + \eta t + \eta \cdot \zeta^2) = \eta, \zeta \} \]

The elimination ordering guarantees that the only constraint for $\zeta$ is BURGER’s equation $b_x$. As $S$ is simple, for any solution $f \in \mathcal{S}(b_\Delta)$ there exists a solution $(g, f) \in \mathcal{S}(\Lambda)$ (cf. (2.3)), implying that $\lambda$ is surjective.

Elements of the $\Delta$-field $F$ are not subjected to splittings and assumed to be non-zero. However, we are able to model the elements of $F$ as differential indeterminates. For example for $F = \mathbb{C}(x)$ with $\Delta = \{ \frac{\partial}{\partial x} \}$, we can study a differential polynomial ring over $\mathbb{C}\{X\}$ instead and replace $x$ by $X$ in all equations and inequations. We subject $X$ to the relation $\mathbb{R}X = 1$ for $X$ being “generic” or $(\frac{\partial}{\partial x} X - 1) \cdot \frac{\partial}{\partial x} X = 0$, if we allow specialization of $X$. Both these cases are considered in examples (3.9) and (3.10), respectively, and will be subject of further study.

Example 3.9. For $F := \mathbb{C}(x)$, $\Delta = \{ \frac{\partial}{\partial x}, \frac{\partial}{\partial t} \}$ and $U = \{ u \}$ consider the special case

\[ (u_t - u_{xx} - x \cdot u_x - u)_x = 0 \quad (5) \]

of the FOKKER-PLANCK equation. We add an auxiliary differential indeterminate $X$ to $U$ and instead examine the equation

\[ (u_t - u_{xx} - X \cdot u_x - u)_x = (X_x - 1)_x, (X_t)_x = 0 \quad (6) \]

in the $\Delta$-ring $\mathbb{C}\{X, u\}$. An elimination ranking $X \gg u$ splits the system (6) into two simple systems:

\[ \begin{align*}
(i) \quad & (u_x \cdot (-u_{xx} + u_{xt} - 2u_x) - u_{xx} \cdot (u_t - u_{xx} - u))_x = , \\
& (u_x \cdot (-u_{xx} + u_{xt} - 2u_x) - u_{xx} \cdot (u_t - u_{xx} - u))_x = , \\
& (u_t - u_{xx} - X \cdot u_x - u)_x = (u_x)_x = \\
(ii) \quad & (u_x)_x = (u_x)_x = (X_x - 1)_x = (X_t)_x =
\end{align*} \]

Due to the ranking, the first two equations in (i) generate $(F\{u\} \cdot \Delta \cdot (u_t - u_{xx} - x \cdot u_x - u)) \cap \mathbb{C}\{u\}$, i.e., they have constant coefficients. These two equations are the derivatives of $\frac{u_t - u_{xx} - x}{u_x} - 2u_x$, which is clearly equivalent to (5) in the case $u_x \neq 0$.

The next example sketches an approach to treat equations with variable coefficients and find submanifolds where solutions behave differently.
Example 3.10. For $F := \mathbb{C}(x, y)$, $\Delta = \{ \frac{\partial}{\partial x}, \frac{\partial}{\partial y} \}$ and $U = \{ u \}$ consider

$$(xy - 1) \cdot u(x, y) = 0$$

and determine solutions on $\mathbb{C}^2$ and its submanifolds. A differential Thomas decomposition over $F\{u\}$ simply reproduces this equation, because $(xy - 1) \notin F \setminus \{0\}$. However, we can model a search for solutions on submanifolds by adding two differential indeterminates $X$ and $Y$ to $U$ and consider the equations. In order to allow splitting the manifold $\mathbb{C}^2$, we add two differential indeterminates $X$ and $Y$ to $U$ which model the $\Delta$-field elements $x$ and $y$. Thus, we have to consider the additional equations $(X_x \cdot (X_x - 1)) = 0$, $(X_y) = 0$, $(Y_y \cdot (Y_y - 1)) = 0$, $(X_x) = 0$, $(Y_x) = 0$, $(X_y) = 0$, $(XY - 1) = 0$. A differential Thomas decomposition with $X, Y \ll u$ yields three systems:

(i) $(XY - 1)_x$, $(X_x)_x$, $(X_y)_x$, $(X)_x$

(ii) $(u)_x$, $(X_x)_x$, $(Y_y \cdot (Y_y - 1)) = 0$, $(X_x) = 0$, $(X)_x$

(iii) $(u)_x$, $(X_x)_x$, $(Y_y \cdot (Y_y - 1)) = 0$, $(X)_x$

System (i) allows an arbitrary function $u$ on the submanifold $M \subset \mathbb{C}^2$ defined by $xy - 1 = 0$ as a solution. The other systems (ii) and (iii) determine $u = 0$ as the only solution on $\mathbb{C}^2 \setminus M$.

4. Implementation

In this section, we describe our implementation of the decomposition algorithm. First, we list some other implementations of triangular decomposition algorithms. Second, we give some typical optimizations to make the computations feasible. Third, we describe our implementation in MAPLE. Fourth, we give benchmarks to get a more detailed and practical comparison between different decomposition algorithms.

4.1. Implementations of Similar Decomposition Algorithms

The RegularChains package by Lemaire et al. (2005) is shipped with recent versions of MAPLE. It contains the Triangularize command, which implements a decomposition of an algebraic variety given by a set of equations by means of regular chains. If the input also contains inequations, the resulting decomposition is represented by regular systems instead. It is possible to make these decompositions disjoint using the MakePairwiseDisjoint command.

The epsilon package by Wang (2003) implements different kinds of triangular decompositions in MAPLE. It is the only software package besides our own that implements the algebraic Thomas decomposition. It closely resembles the approach that Thomas (1937, 1962) suggested, i.e., polynomials of higher leader are considered first. All polynomials of the same leader are combined into one common consequence, resulting in new conditions of lower leader. These are not taken into account right away and will be treated in later steps. Contrary to our approach, one cannot reduce modulo an unfinished system. Therefore, one needs extra inconsistency checks to avoid spending too much time on computations with inconsistent systems. epsilon implements such checks in order to achieve good performance.

The MAPLE packages diffalg by Boulier and Hubert (1996-2004) and DifferentialAlgebra by Boulier and Cheb-Terrab deal with ordinary and partial differential equations as described by Boulier et al. (2009). They compute a radical decomposition of a differential ideal, i.e., a description of the vanishing ideal of the Kolchin closure (Kolchin, 1973, §IV.1) of the set of solutions. Computation of integrability conditions is driven by reduction of $\Delta$-polynomials (Rosenfeld, 1959, Sect. 2), which are the analogon of $s$-polynomials in differential algebra. Just like in RegularChains, this approach usually does not give disjoint solution sets, although in principle disjointness might be achieved. The diffalg package has been superseded by DifferentialAlgebra in MAPLE 14. DifferentialAlgebra is based on the BLAD-libraries by Boulier (2004-2009) which have been designed as a set of stand-alone C-libraries with an emphasis on usability for non-mathematicians and extensive documentation.
4.2. Algorithmic Optimizations

In this subsection, we describe algorithmic optimizations helpful for a reasonably fast implementation of the Decompose algorithm.

In our algorithm, pseudo remainder sequences for the same pairs of polynomials are usually needed several times in different branches. As these calculations are expensive in general, our implementation always keeps the results in memory and reuses them when the same pseudo remainder sequence is requested again to avoid repeated computations.

Coefficient growth is a common problem in elimination. Polynomials should be represented as compact as possible. Once we know that the initial of a polynomial is non-zero, the content of a polynomial (in the univariate sense) is non-zero, too. Thus, every time an initial is added to the system as an inequation, we can divide the polynomial by its content. Additionally, the multivariate content, which is an element of $F$, can be removed.

The reduction algorithms (2.6) and (3.3) do not recognize that non-leading coefficients are zero. However, we can reduce the coefficients modulo the polynomials of lower leader, in addition to reduction of the polynomial itself. Thereby, in some cases the sizes of coefficients decrease, in other cases they increase. The latter is partly due to multiplying the whole polynomials with the initials of the reductors. Finding a good heuristic for this coefficient reduction is crucial for efficiency.

Factorization of a polynomial improves computation time in many cases. More precisely, the system $S \cup \{(p \cdot q) = 0\}$ decomposes disjointly into $(S \cup \{p = 0\}, S \cup \{p \neq 0, q = 0\})$ and the system $S \cup \{p \neq 0, q \neq 0\}$ is equivalent to $S \cup \{p \neq 0, q \neq 0\}$. In most cases, the computation of two smaller problems resulting from a factorization is cheaper than the computation of the big, original problem. This idea extends to factorizations over an extension of the base field: Let $Y_i := \{x_j : x_j < x_i, (S_T)_{x_i}^z = 0\}$ and $Z_i := \{x_j : x_j < x_i, (S_T)_{x_i}^z = 0\}$. Assume that $(S_T)_{x_i}^z$ is irreducible over the field $F_i := F(Z_i)[Y_i]/\langle(S_T)_{x_i}^z\rangle$ for all $i \in \{1, \ldots, n\}$, where $\langle(S_T)_{x_i}^z\rangle$ is the ideal generated by $F(Z_i)[Y_i]$. Factorization over $F_n$ instead of $F$ may split the polynomial into more factors, but it is not clear whether this improves runtime. Preliminary tests show that factorization over $F$ should be preferred for $F = \mathbb{Q}$.

In the algebraic algorithm, polynomials need not be square-free when they are inserted into the candidate simple system. Efficiency can sometimes be improved by postponing the computation of the square-free split as long as possible. However, this is not possible for the differential case. Differential polynomials need to be made square-free to ensure that their separant is non-zero, i.e. non-trivial prolongations have a non-zero initial.

In the differential case, application of criteria can decrease computation time by avoiding useless reductions of non-reductive prolongations. JANET’s combinatorial approach already avoids many reductions of $\Delta$-polynomials, as used in other approaches (see Gerdt and Yanovich (2006)). In addition, we use the involutive criteria 2-4 (cf. Gerdt and Blinkov (1998a); Gerdt (2005); Apel and Hemmecke (2005)), which together are equivalent to the chain criterion. Applicability of this criterion in the non-linear differential case was shown in (Boulier et al., 2009, §4, Prop. 5).

The axioms of a selection strategy (see Definition (2.22)) already strongly limit the choice for the polynomial considered in the current step. However, the remaining freedom is another important aspect for the speed of an actual implementation. We will describe different selection strategies in §4.3 and compare them in the benchmarks.

As described up to now, the algorithm often keeps on computing with inconsistent systems. We want to optimize the algorithm to detect the inconsistencies as early as possible. This allows the algorithm to discard inconsistent systems as early as possible. One of the problems is selection strategies that postpone the costly treatment of inequations. A test to detect whether inequations in $S_Q$ reduce to zero is comparably cheap.

Another possible improvement is parallelization, since the main loop in Decompose (2.25) can naturally be used in parallel for different systems.

4.3. Selection strategies

We consider our two main approaches to selection strategies (see Definition (2.22)).
1. The “equations first” strategies: Select only chooses an inequation if \( Q \) does not contain any equations. Among the equations or inequations, it prefers the ones with smallest leader.

2. The “leader first” strategies: Select always chooses an equation or inequation with the smallest leader occurring in \( Q \). If there are both equations and inequations with that leader, it chooses an equation.

In both approaches, if the above criteria do not yield a unique choice, we compare the leader of the initial and choose the smaller one. We apply the last test recursively to the initial of the initial and so on. At this point, it is still possible that we fail to make a unique selection. However, these cases are rare and there does not seem to be a considerable performance advantage for any choice. Therefore, it suffices to make an arbitrary (but preferably unique) choice.

In our experimental observation “leader first” strategies usually produce decompositions with less systems, while “equations first” strategies are more efficient (cf. §4.5).

### 4.4. Implementation in MAPLE

Both the algebraic and the differential case of the THOMAS decomposition algorithm have been implemented in the MAPLE computer algebra system. Packages can be downloaded from our web page (Bächler and Lange-Hegermann (2008-2011)), documentation and example worksheets are available there.

The main reason for choosing MAPLE for the implementation is the collection of solvers for polynomial equations, ODEs, and PDEs already present. Furthermore, fast algorithms exist for polynomial factorization over finitely generated field extensions of \( \mathbb{Q} \) and for gcd computation.

The \texttt{AlgebraicThomas} package includes procedures to compute a THOMAS decomposition, reduce polynomials modulo simple systems and compute counting polynomials (cf. Plesken (2009a)). Furthermore, it can represent the complement and intersection of solution sets as decompositions into simple systems. Finally, a comprehensive THOMAS decomposition can be computed, this topic will be discussed in a later publication.

**Example 4.1.** We demonstrate how to use the \texttt{AlgebraicThomas} package by computing a decomposition of the system in example (2.5).

```maple
> with(AlgebraicThomas):
p := a*x^2 + b*x + c;
p := x^2 a + x b + c
>S := AlgebraicThomasDecomposition([p], [x,c,b,a]);
S := \[[x^2 a + x b + c = 0, 4 c a - b^2 \neq 0, a \neq 0], [2 x a + b = 0, 4 c a - b^2 = 0, a \neq 0], [x b + c = 0, b \neq 0, a = 0], [c = 0, b = 0, a = 0]\]
Information about leader and main degree can optionally be included in the output.
>map(printSystem, S, ["PT", "LR"]);
[[[x^2 a + x b + c = 0, x^2], [4 c a - b^2 \neq 0, c], [a \neq 0, a]],
[[2 x a + b = 0, x], [4 c a - b^2 = 0, c], [a \neq 0, a]],
[[x b + c = 0, x], [b \neq 0, b], [a = 0, a]], [[c = 0, c], [b = 0, b], [a = 0, a]]]
It is possible to include inequations in the input to exclude some degenerate cases:
> q := a<0;
q := a \neq 0
> T := AlgebraicThomasDecomposition([p, q], [x,c,b,a]);
T := [[x^2 a + x b + c = 0, 4 c a - b^2 \neq 0, a \neq 0], [2 x a + b = 0, 4 c a - b^2 = 0, a \neq 0]]
```

Features for the differential package \texttt{DifferentialThomas} include arbitrary differential rankings, using special functions implemented in MAPLE as differential field elements, computation of power series solutions, and a direct connection to the solvers of MAPLE for differential equations.
Example 4.2. We treat the following control theoretic example taken from Diop (1992).

```maple
> with(DifferentialThomas):
> ComputeRanking([t], [x2, x1, y, u], "EliminateFunction");
This creates the differential polynomial ring \( \mathbb{Q}\{x^{(2)}, x^{(1)}, y, u\} \) for \( \Delta = \{\frac{\partial}{\partial t}\} \). Here \( u \) indicates the input, \( x^{(1)} \) and \( x^{(2)} \) the state, and \( y \) the output of the system. The chosen ranking “<” is the elimination ranking with \( x^{(2)} > x^{(1)} > y > u \) for all \( i, j, k, l \in \mathbb{Z}_{\geq 0} \).

> L:=[x1[1]-u[0]*x2[0],x2[1]-x1[0]-u[0]*x2[0],y[0]-x1[0]]:
We follow (Diop, 1992, Ex. 1) and compute the external trajectories of a differential ideal generated by \( L \), i.e. intersect this differential ideal with \( \mathbb{Q}\{y, u\} \).

> res:=DifferentialThomasDecomposition(L,{});
res := [DifferentialSystem, DifferentialSystem]

We show the equations and inequations of the differential systems not involving \( x^{(1)} \) or \( x^{(2)} \). The chosen ranking guarantees that the systems shown determine the external trajectories of the system:

```maple
> PrettyPrintDifferentialSystem(res[1]):remove(a->has(a,[x1,x2]),%);
\[ -u(t) \left( \frac{d^2}{dt^2} y(t) \right) + \left( \frac{d}{dt} y(t) \right) u(t)^2 + \left( \frac{d}{dt} y(t) \right) \left( \frac{d}{dt} u(t) \right) + y(t) u(t)^2 = 0, u(t) \neq 0 \]
> PrettyPrintDifferentialSystem(res[2]):remove(a->has(a,[x1,x2]),%);
\[ \frac{d}{dt} y(t) = 0, u(t) = 0 \]

These systems, having disjoint solution sets, are identical to the ones found in Diop (1992).

4.5. Benchmarks

In this subsection, we compare our two MAPLE packages to the other implementations of triangular decompositions mentioned in §4.1 using benchmarks. Not all of the implementations compute equivalent results. This should be considered when comparing the timings. We omitted examples where all tested systems took less than one second to complete the computation or could not be computed by any software package.

All benchmarks have been performed with Linux x86-64 running on a third generation Opteron, 2.3 GHz. The time limit has been set to 3 hours and available memory is limited to 4 GB. All times are given in seconds. The polynomial multiplication in MAPLE 14 benefits from a new parallel implementation (cf. Monagan and Pearce (2009)). Nonetheless, we state the total CPU time in our benchmarks, as returned by MAPLE’s time command.

By default, both of our MAPLE packages behave as follows:

- Polynomials are factorized over \( \mathbb{Q} \).
- The content of polynomials is removed.
- The selection strategy is an “equations first” strategy, as described in §4.3.
- After reducing a polynomial, we always reduce its coefficients fully.
- Inequations in \( S_Q \) are reduced for early inconsistency checks.

See §4.2 for details.
4.5.1. Algebraic Systems

For testing the AlgebraicThomas package, we used two sets of examples, namely, the test examples from the polsys50 file in Wang’s epsilon package (Wang (2003)) printed in table 1 and the examples from Chen et al. (2007) as shown in table 2.

In contrast to Algorithm 2.25, the implementation in the AlgebraicThomas package inserts equations or inequations into \( S_T \) without making them square-free first. It delays this computation as long as possible, sometimes until the end of the decomposition. This avoids some expensive and unnecessary discriminant computations entirely.

We compared AlgebraicThomas with the RegularChains package from MAPLE 14 and epsilon. We also tested the AlgebraicThomas and RegularChains packages in different configurations. The timings in MAPLE 14 of the following procedures are being compared:

- (RC1) RegularChains[Triangularize].
- (RC2) RegularChains[Triangularize] with the 'output'=’lazard’ option set.
- (RC3) RegularChains[Triangularize] with the 'radical'=’yes’ option set.
- (DW1) epsilon[RegSer].
- (DW2) sisys[simser].
- (AT1) AlgebraicThomasDecomposition.
- (AT2) AlgebraicThomasDecomposition with factorization disabled.
- (AT3) AlgebraicThomasDecomposition with a “leader first” selection strategy (cf. §4.3).

\[\text{Table 1: Comparison of algebraic decompositions 1: polsys50 from Wang (2003)}\]

| Name | RC1 | RC2 | RC3 | DW1 | DW2 | AT1 | AT2 | AT3 | AT4 |

| 29   | 0.3 | 0.5 | 0.4 | 0.3 | 0.3 | 0.3 | 55.2 | 0.3 | 0.3 |
| 30   | > 4GB | > 4GB | > 4GB | > 4GB | > 4h | 45.3 | 42.9 | 40.8 | > 4GB |
| 31   | > 4GB | > 4GB | > 4GB | > 4GB | > 4h | > 4h | > 4h | > 4h | > 4h |
| 33   | 3.4 | 3.6 | 3.2 | 1.3 | 1.3 | 3.5 | 66.9 | 15.2 | 1.1 |
| 34   | 911.5 | 916.9 | 926.5 | > 4h | > 4GB | > 4GB | > 4GB | > 3h | > 4GB |
| 35   | 1.5 | 1.5 | 1.6 | 1.2 | 1.3 | 1.7 | 4.9 | 7.3 | 0.5 |
| 39   | 0.6 | 0.7 | 0.8 | 1.2 | 1.9 | 0.6 | 1.0 | 8.0 | 0.5 |
| 41   | 1.5 | 1.5 | 1.6 | 1.5 | 1.7 | 7.0 | 1.4 | 0.6 | 114.5 |
| 43   | 0.7 | 0.7 | 0.7 | 3.1 | 4.4 | 0.2 | 1.0 | 0.2 | 0.2 |
| 44   | 24.5 | 17.2 | 24.1 | 3.4 | 4.2 | 1.2 | 1.7 | 0.8 | > 4GB |
| 47   | 1.3 | 1.7 | 1.4 | 2.8 | 6.6 | 13.0 | > 3h | 11.1 | 92.4 |
| 49   | 0.3 | 0.3 | 0.3 | 610.2 | 32.1 | 0.5 | > 3h | 0.5 | 0.5 |
We compare table 1 and 2 within our own implementation. We observe, that (AT2) is much slower than (AT1) and, thus, conclude that factorization is vital to make many computations feasible. In a few examples, we see the relative advantage of the default selection strategy compared to the one used in (AT3). Generally speaking, disabling coefficient reduction increases computation time for (AT4), but there are some strong counterexamples to this observation. This indicates that different strategies for coefficient reduction, as seen in (AT1) and (AT4), should be investigated further.

The programs sisys[simser] (DW2) and AlgebraicThomasDecomposition (AT1-4) are the only ones that compute a Thomas decomposition. All test examples that could be computed by (DW2) could also be computed by (AT1). However, there are some examples that RegularChains (RC1) or epsilon (DW1) could treat, but we could not decompose into simple systems. Moreover, the test examples indicate that (RC1) is in general faster than (AT1) in the positive-dimensional case. Our evaluation suggests that this is due to the strict square-free property of simple systems. In the zero-dimensional case, however, the situation is less clear, since there are examples where (RC1) is faster than (AT1) and vice versa.

### 4.5.2. Differential Systems

We compared DifferentialThomas with the packages diffalg and DifferentialAlgebra. Finding a suitable set of benchmark examples for the differential case was more difficult. We are not aware of any sets of standard benchmarks. Thus, we used a collection of examples, which we came across in our work. These examples are published on our homepage (Bächler and Lange-Hegermann (2008-2011)).

The timings of the following procedures are being compared:

- (DA) DifferentialAlgebra[Rosenfeld_Grobner].
Table 3: Benchmarks for ODE systems

| Name                    | DA  | da  | DT1  | DT2  | DT3  | DT4  |
|-------------------------|-----|-----|------|------|------|------|
| Diffalg1                | 2.9 | 2.9 | 832.5 | 8932.4 | 30.0 |
| LLG3                    | 0.5 | > 3h | 5.4  | 5.6  | 4.4  | 4.9  |
| LLG4                    | 0.3 | 19.1 | 2.6  | 37.4 | 20.3 | 4.0  |
| ODE1                    | 2.4 | 3.7  | 0.6  | 0.3  | 0.6  | 0.8  |
| ODE6                    | 2.3 | 1.5  | 0.8  | 1.2  | 0.6  | 0.8  |
| ODE7                    | > 3h | > 3h | 3.2  | 60.8 | 47.2 | 5.4  |
| kepler vs newton        | 0.7 | 0.9  | 1.4  | 2.8  | 0.8  | 2.0  |
| kepller1                | 0.1 | 0.2  | 1.1  | 0.6  | 0.8  | 1.1  |
| kepller2                | 0.1 | 0.1  | 1.3  | 1.5  | 1.1  | 0.8  |
| kepller3                | 0.1 | 0.2  | 1.1  | 0.6  | 0.7  | 1.1  |
| murray1                 | 0.1 | 0.4  | 1.9  | 2.4  | 1.7  | 2.2  |
| murray2                 | 0.1 | 0.1  | 0.7  | 1.4  | 0.8  | 0.6  |

Table 4: Benchmarks for PDE systems

| Name                    | DA  | da  | DT1  | DT2  | DT3  | DT4  |
|-------------------------|-----|-----|------|------|------|------|
| Cyclic 5 variant1       | > 3h | 2.9  | 1.3  | 1.5  | 1.4  | 1.2  |
| Cyclic 5 variant2       | > 3h | > 3h | 2.3  | 2.6  | 0.7  | 2.3  |
| Diffalg2                | 0.5 | 0.3  | 1.4  | 1.5  | 41.5 | 1.2  |
| Diffalg3                | 0.2 | 0.5  | 0.9  | 0.6  | 1.6  | 0.7  |
| Ibragimov 2, 17.9c      | > 3h | > 3h | 18.4 | > 3h | 40.8 | 12.3 |
| PDE6                    | > 4GB | > 4GB | 11.1 | 23.0 | > 4GB | 16.5 |
| PDE7                    | > 4GB | 116.7 | 91.3 | 83.3 | > 4GB | 41.4 |
| PDE8                    | > 4GB | > 4GB | 6.8  | > 4GB | 14.2 | 7.5  |
| Riquier 1b              | 0.1 | 0.1  | 1.9  | 1.9  | 1.9  | 2.0  |
| Riquier 3a              | 0.3 | 0.2  | 0.8  | 1.1  | 0.5  | 0.6  |
| Riquier 3b              | 0.6 | 0.6  | 1.4  | 1.7  | 1.4  | 1.2  |
| boulier                 | > 3h | 546.4 | 2.5  | 1690.9 | 2.6  | 1.5  |
| cyclic 6                | > 4GB | 571.9 | 160.7 | 159.8 | 349.6 | 154.1 |
| noon6                   | > 4GB | 72.6  | 40.6 | 36.8 | 63.7 | 31.0 |

- (da) diffalg[Rosenfeld_Groebner]\(^{12}\).
- (DT1) DifferentialThomasDecomposition.
- (DT2) DifferentialThomasDecomposition with factorization disabled.
- (DT3) DifferentialThomasDecomposition with a “leader first” selection strategy (cf. §4.3)
- (DT4) DifferentialThomasDecomposition with coefficient reduction disabled.

We want to mention one further example not included in the benchmark table. It is the test example 5 of diffalg. None of the packages in their default setting could compute this example. Still, diffalg and DifferentialAlgebra were able to do so instantaneously by a change of ordering strategy.

The comparison between (DT1), (DT2) and (DT3) is similar to the algebraic case. In particular, factorization should be enabled and the default selection strategy should be preferred. In contrast to the algebraic implementation, the comparison of (DT1) and (DT4) is less conclusive.

All test examples which could be computed by DifferentialAlgebra or diffalg could also be computed by our default strategy (DT1). For ODEs, the three packages show similar timings, but for PDEs, DifferentialThomasDecomposition appears to be faster. This might be explained by the involutive approach, which we utilize to make the subsystems coherent. A similar result can be found for the GINV-project (cf. Blinkov et al. (2010a), Blinkov et al. (2010b)).

\(^{12}\)with \_env\_diffalg\_uses\_DifferentialAlgebra:=false
5. Acknowledgments

The contents of this paper profited very much from numerous useful comments and remarks by Wilhelm Plesken. The authors thank him as well as Dongming Wang, François Boulier and François Lemaire for fruitful discussions. The second author (V.P.G.) acknowledges the Deutsche Forschungsgemeinschaft for the financial support that made his stay in Aachen possible. The presented results were obtained during his visits. The contribution of the first and third author (T.B. and M.L.-H.) was partly supported by Schwerpunkt SPP 1489 of the Deutsche Forschungsgemeinschaft.

Finally, our gratitude goes to the anonymous referees for valuable comments, for pointing out informative references and for taking the time to verify the results of our benchmarks.
