Abstract

Introduction: the association of Tuberculosis and Diabetes Mellitus is a cause of concern for the health sector. The coexistence of these two highly prevalent diseases has made the already existing treatments very complex. This issue is of particular significance to developing countries like India that bear a significant burden of these two diseases. Methods: retrospective analysis of 1000 consecutively admitted patients in a tertiary care hospital were analyzed for the coexistence of Tuberculosis and Diabetes Mellitus. Results: the study found that a significant proportion of diabetic patients had coexistent tuberculosis (65.5%). Rural population was predominantly affected in both the genders. The study observed that the coexistence of these two conditions increased with advanced age. Conclusion: the coexistence of Diabetes Mellitus with Tuberculosis needs to identified early and adequately addressed. The rural population needs to be educated about these two conditions and seek timely medical care.

Introduction

Tuberculosis and Diabetes Mellitus are the two main diseases that are widely prevalent in India. The convergence of these two conditions has led to increased rates of prolonged treatment, relapse and death. The Tuberculosis-Diabetes Mellitus (TB-DM) epidemic is a challenge for India and other developing countries that constitute a major global burden of these two diseases. More than 95% of the total deaths from Tuberculosis worldwide occur in low and middle income group countries. India reports more than two lakh deaths annually from Tuberculosis while the African continent alone reported more than 3,90,000 deaths related to this disease in the year 2009 [1]. With the implementation of Revised National Tuberculosis Control Programme (RNTCP), India has been able to reduce the prevalence of Tuberculosis to a great extent. According to a WHO report, the prevalence of Tuberculosis in India has reduced from 465 per 100,000 in 1990 to 230 per 100,000 in 2012 [2]. Still India reported around 2.3 million cases of Tuberculosis in 2013 of a total 9 million cases that occurred worldwide, thus constituted one fourth of the annual global burden of the disease [3]. On the other hand, the prevalence of Diabetes Mellitus is increasing globally. In the year 2013, there were more than 380 million diabetic patients in the world. Its prevalence is likely to cross 590 million by 2030. A vast majority of diabetics (more than 80%) belong to low-and middle-income countries and a majority of the patients are in their 5th and 6th decade of their lives. During 2013, there were around 65 million diabetic patients in our country and the number is likely to reach 109 million by 2035 [4-5]. The WHO reports that 11% urban and 3% of rural population in India above the age of 15 years have Diabetes Mellitus.

The tuberculosis-diabetes Mellitus epidemic

It is known that diabetics have a greater susceptibility to develop Tuberculosis as compared to non-diabetics. It is believed that the impairment of immunity in long term diabetics makes the patients prone to a number of microbial infections including Mycobacterium Tuberculosis. The hyperglycemia in Diabetes Mellitus is believed to favor the growth of the Tuberculosis bacilli. The association between Tuberculosis and Diabetes Mellitus is bidirectional. One of the first line anti tubercular drugs, Rifampicin, is known to interfere with the metabolism of oral hypoglycemic agents and hence affect glycaemic control [6]. The Diabetes Mellitus increases the chance of adverse treatment outcome, relapse and death in patients of Tuberculosis [7-9]. The patients with these two conditions coexisting are more likely to be sputum positive [10] and usually require longer time to be rendered sputum negative. In addition, such patients also have a much higher risk (about 4 times) of death during treatment of Tuberculosis. In our country, a substantial number of Tuberculosis patients have Diabetes Mellitus [11]. As the number of diabetics is rising worldwide, there are greater chances that Diabetes Mellitus will interfere with control and care of Tuberculosis [10,12]. The convergence of Diabetes Mellitus and Tuberculosis has increased the interest to study various aspects of human immunity in relation to Tuberculosis that can be helpful to provide better care to the general public.

Methods

The present retrospective study was conducted at Department of Tuberculosis and Chest Diseases, Government Medical College, Patiala, Punjab, India. A total of 1000 consecutively admitted cases for various respiratory diseases from April 2013 to August 2013 were subjected to detection of Tuberculosis and Diabetes Mellitus. Only those patients in whom these two conditions were confirmed to coexist were included in the study. The cases in which only one of the two conditions was present were excluded from the study. The detection of Tuberculosis was based on history, signs & symptoms (i.e. fever, cough, expectoration, loss of weight, loss of appetite, fatigue etc) and investigations (including Chest X rays, sputum examination for Acid Fast Bacilli, bronchoscopy etc). Then the diagnosed patients of Tuberculosis were asked of history of Diabetes Mellitus as these two conditions are known to coexist in the same individual. The patients of tuberculosis patients who confirmed their Diabetes Mellitus (i.e. already on medications for Diabetes mellitus) were included as such in the study. Those patients who did not know about their Diabetes Mellitus status were subjected to fasting blood glucose examinations. They were then either included or excluded from the study based on the presence or absence of Diabetes Mellitus. The patients of all age groups and both genders were included in the study. The patients with other medical conditions like COPD, asthma, heart diseases, HIV, long term use of corticosteroids, malignancies etc were excluded from the study.

Result

Of a total of 1000 cases studied, the coexistence of tuberculosis with diabetes mellitus was found only in 76 cases. Out of these, 61 had pulmonary tuberculosis and 15 had extra pulmonary tuberculosis. All these cases were included in the study. Thus, only 76 cases out of a total of 1000 cases fulfilled the inclusion criteria. The study population included only the confirmed cases of tuberculosis. In 544 cases (54.4%) only tuberculosis (but not Diabetes mellitus) was present and therefore excluded from the study. There were 340 patients who were admitted with respiratory problems other than tuberculosis and hence also excluded from the study. The diabetes mellitus in association with other respiratory problems (but not tuberculosis) was present in 40 cases and hence excluded from the study. The males constituted a majority of cases in both Tuberculosis-Diabetes Mellitus group (56.5%) and in Tuberculosis only group (60.3% cases). The mean age of Tuberculosis-Diabetes Mellitus patients was found to be 56.67±12.24 years. The mean age of Tuberculosis only patients was 41.60 years ±18.66 years. The maximum number of cases of Tuberculosis-Diabetes Mellitus belonged to 51-60 years age group (35.5%) followed by above 60 years age group (30.1%). No case of Tuberculosis-Diabetes Mellitus was reported below the age of 30 years. In contrast, the maximum number of cases of Tuberculosis only group belonged to 21-30 years age group (21.3%) followed by 31-40 years age group (16% each). The least number of cases belonged to 0-10 year’s age group (0.9%) (Table 1). The present study observed that most of the Tuberculosis-Diabetes Mellitus patients belonged to rural areas (68.4%). Similar results were also obtained in Tuberculosis only group (72.2%) (Table 2). The examination of radiological investigations did not reveal any significant differences between the two groups (Table 3).

Discussion

The present study retrospectively analyzed 1000 consecutively admitted cases to a leading Tuberculosis and chest hospital of north India for the coexistence of Tuberculosis and Diabetes Mellitus. These cases constituted 11.6% of the total admitted cases during
the study period. The present study observed that males were the main victims in a majority of cases. Similar findings have been reported from other parts of India, Japan and Ethiopia [13-17]. Contrasting results (female preponderance) were reported from Iran [18]. The poor treatment results in males might be because of their non-adherence to treatment [19-21]. The male predominance can possibly be explained by their more frequent exposure to Tuberculosis patients due to greater involvement in outdoor activities. A number of studies have observed that Diabetes Mellitus is also more commonly associated with males. The greater stresses of life have also been observed in males and it could lead to overeating making them more susceptible to fluctuations in blood sugar levels. The mean age in the Tuberculosis-Diabetes Mellitus patients in the present study was found to be 56.67± 12.24 years while in cases of Tuberculosis only, it was 41.60 ± 18.66 years. Similar results were reported from Iran [22] and Ethiopia [17]. It has been reported that age above 46 years is associated with poor treatment results [23]. The decreased immunity and general decline of physical health and lesser ability to reach the health care centers that occur with advancing age might be the reasons for poor results in advanced ages [24-25]. In the age of 40 to 60 years, increased involvement with work related activities might be associated with poor adherence with treatment [20]. Most of the cases in the present study belonged to rural area. Concordant findings were found in Malaysia [20]. However, this study is in disagreement with other Indian studies that reported greater involvement of urban population in both Tuberculosis and Diabetes Mellitus as it is associated with increased crowding, sedentary life and urbanization [26]. Delay in seeking medical care and poor compliance with treatment might have contributed to greater incidence among the rural population in this region of the country. No statistical significance was observed among the distribution of different types of lesions in the lungs.

Conclusion

The present study concluded that early screening for Diabetes Mellitus in Tuberculosis patients is likely to increase the detection of Diabetes Mellitus. This will lead to an early recognition of the coexistence of these two conditions and therefore appropriate measures could be taken to simultaneously treat these conditions. Though RNTCP programme has been quite effective in India, it can be further improved to monitor and report such a coexistence of Tuberculosis with other conditions like Diabetes Mellitus and achieve a further fall in morbidity and mortality.

What is known about this topic

- Diabetes is important risk factor for Tuberculosis and might affect its presentation and treatment and outcome;
- Tuberculosis induces glucose intolerance and worsens the glycaemic control in Diabetic patients;
- Poorly controlled DM leads to multiple complications and increased susceptibility to infections. Diabetes leads to increased susceptibility to Tuberculosis via different mechanisms. One mechanism include those directly related to hyperglycemia and cellular insulinopenia, and other is effects on macrophage and lymphocyte function, leading to diminished ability to contain the organism. Altered immunity in DM leads to increased microbial burden which lead to longer time of conversion and higher rate of relapse.

What this study adds

- In the area of present study, there is a large population of diabetics and tuberculosis patients and there is increasing number of cases of multidrug resistance tuberculosis. The poorly controlled DM is an important factor that contributes towards drug resistance;
- We reviewed epidemiology of TB and DM and provided a synopsis of the evidence for the role of Diabetes mellitus in susceptibility to, clinical presentation of, and response to treatment for tuberculosis;
- There are only a few studies that have been conducted in this area of India and hence more research is essential to counter the coexistence of these two medical conditions
