Abstract

Effective treatment of glioma still stands as a challenge in medical science. The work aims for the fabrication and evaluation of lipid based nanostructures for improved delivery of lomustine to brain tumor cells. Experimental formulations (LNLs) were developed by modified lipid layer hydration technique and evaluated for different \textit{in vitro} characteristics like particle size analysis, surface charge, surface morphology, internal structure, \textit{in vitro} drug loading, drug release profile etc. Anticancer potential of selected LNLs was tested \textit{in vitro} on C6 glioma cell line. Electron microscopic study depicted a size of less than 50 nm for the selected LNLs along with 8.8% drug loading with a sustained drug release tendency over 48 h study period. Confocal microscopy revealed reasonable internalization of the selected LNL in C6 cells. LNLs were found more cytotoxic than free drug and blank nanocarriers as depicted from MTT assay. The selected LNL showed improved pharmacokinetic profile both in blood and brain in the experimental mice models along with negligible hemolysis in mice blood cells. Further studies are warranted for the future translation of LNLs at clinics.

Keywords: Lomustine; lipid nanostructure; C6 glioma cells; cellular uptake; pharmacokinetic; hemolysis

1. Introduction

Effective treatment of brain tumor remains a challenge in medical science. Gliomas are the most common type of tumors of brain and central nervous system. Based on the type of primary cells along with molecular characteristics, gliomas can be of astrocytomas, ependymomas, oligodendrogliomas etc. Glioma is characterized by its uncontrolled cellular proliferation, diffused infiltration along with significant angiogenesis. Glioma at its fourth stage is referred to as glioblastoma multiforme, which is the most dangerous stage with poor prognosis and an average survival rate of 1–2 years. In spite of all the advanced medical strategies, death rate of glioma patients is increasing at an alarming rate all over the world. The treatment failures may be attributed to the delicate and sensitive characteristics of brain tissue, which limits effective application of surgery or radiation therapy; whereas presence of blood-brain barrier (BBB) further worsens the case. BBB is the most complex, tight endothelial barrier, which strictly checks the entry of therapeutic molecules into the brain and thus stands as a serious challenge for chemotherapy. Although, many conventional anticancer drugs are available in clinical practice, but majority of them fails to maintain the desired therapeutic concentration in the brain tissue for a sufficient period of time due to their inability to pass effectively through BBB. Some lipophilic drugs like carmustine, temozolomide, bevacizumab etc. are being claimed to cross BBB, but shorter half-life along with severe dose related toxic effects associated with them throw additional challenges to get desired treatment outcomes. In this context, novel drug delivery strategies like nanoliposomes, nanoparticles, polymeric micelles, niosomes, dendrimers etc. have been investigated
widely in past years to improve the efficacy of conventional chemotherapeutic agents for the treatment of glioma.\textsuperscript{10,11,12} However, till today, very few of them have been approved to be used in clinical practice. Among various types of nanocarrier platforms, nanosize lipid based vesicular carriers have been largely preferred for successful delivery of toxic chemotherapeutic drugs to brain.\textsuperscript{13,14} Due to high lipophilic nature as well as ultra small size, they fulfill the prime requisite criteria to overcome BBB to get into the brain. Phospholipid based nanostructures (NLs) are the ultra-micron size phospholipid vesicles consisting of self assembled lipid bilayers enclosing small aqueous phase in their core.\textsuperscript{15} Due to this architectural uniqueness, they act as dual platform for both hydrophobic and hydrophilic molecules.\textsuperscript{16} The hydrophobic/lipophilic agents get entrapped in the outer lipid bilayer, where as the hydrophilic agents remain encapsulated in the aqueous core.\textsuperscript{17} NLs owing to their lipophilicity, biodegradability, non-immunogenicity, bio-compatibility, sustained drug release property, ease of surface manipulation etc. have drawn the attention of formulation scientists as preferred drug delivery vehicles in nanomedicine based research.\textsuperscript{17,18} Due to sustained delivery of the loaded cargo as well as site-specific delivery, the dose of the cytotoxic anti-cancer drugs is expected to be reduced, which leads to better treatment outcome and fewer side effects.

Lomustine (LS) is a nitrosourea class of antineoplastic agent, which is used in the treatment of various types of malignancies, including glioma.\textsuperscript{19} It inhibits protein synthesis by causing alkylation and cross-linking in the nucleic acids (DNA/RNA). Being lipophilic in nature, it posses the capacity to cross BBB, however, its short half life and deadly side effects like severe bone marrow depression, leucopenia, etc. limits its effective use in the treatment of glioma.\textsuperscript{20,21} Thus, there is a need to develop novel strategies for the safer and effective delivery of LS to brain and thereby reducing the dose-related side effects associated with the conventional forms.

Kevin A. Harvey et al. studied anticancer properties of LS in conjunction with docosahexaenoic acid (DHA) in glioblastoma cell lines. They studied effects of LS, alone and in combination with DHA in C6 human glioblastoma cell line.\textsuperscript{19} In another study, LS nanoparticles prepared by molecular envelope technology was tested on C6 glioblastoma bearing animal model.\textsuperscript{21} Another work reported an optimized method of development of poly (dl-lactide-co-glycolide) based LS nanoparticles and investigated their anticancer potential in lung cancer cell line L132.\textsuperscript{22} However, to our knowledge, no reports are available on the anticancer potential of lomustine loaded lipid nanostructures (LNLS) on C6 glioma cells and also on their \textit{in vivo} plasma/brain pharmacokinetic (PK) profile. Haemolysis assay for LNLS in mice RBC further adds novelty to the work, which is an important piece of information for safe biomedical application.

In the lieu of which, the present study aims to investigate the anticancer potential of optimized LNLS on rat glioma cells along with evaluation of both blood and brain PK profiles in experimental animal model. The LNLS were prepared by conventional method with optimization of critical manufacturing conditions to achieve the desired nanosize. Preferably, we wanted to keep the size of LNLS within a range of 50–100 nm to achieve effective permeation into brain as well as to escape from reticuloendothelial system. The experimental LNLS were evaluated by different \textit{in vitro} techniques and the optimized formulation was tested for its \textit{in vitro} anticancer effectiveness in C6 glioma cells. Further \textit{in vivo} blood and brain PK study was also carried out in experimental mice to estimate the potentiality of the optimized formulation both qualitatively and quantitatively for the treatment of glioma.

2. Materials & Methods

2.1. Materials

LS was obtained as a gift sample from Cipla laboratories (Goa, India). Cholesterol (CHL), soya-L-a-lecithin (SL), 1,2-distearyl-sn-glycero-3-phosphatidyethanolamine (DSPE) were procured from Merck (Mumbai, India). Chloroform, butylated hydroxyl anisole (BHA), fluorescein isothiocyanate (FITC), were purchased from Hi-media Laboratories Pvt. Ltd (Mumbai, India). 4’,6-Diamidino-2-phenylindole) (DAPI) and tetrazolium dye (Sigma-Aldrich (Banglore, India)). C6 glioma cells were procured from National Center for Cell Science (Pune, India). All other chemicals used in the experiment were of analytical grade.

2.1.1. Animals

For PK studies, healthy Swiss albino mice of either sex (male: female ratio 1:1) were used. All animal related experiments were in accordance with CPSCEA guidelines. Animals were kept in polipropylene cages and maintained in the Jadavpur university animal house at normal room temperature (20–25 °C), 55% relative humidity with normal day and night cycle. Before experiments, animals were properly fed standard diet and drinking water \textit{ad libitum}. The guidelines of Animal Ethical Committee, Jadavpur University were followed strictly during the entire study period. The animals were kept for three weeks in the animal house environment before study. A total number of 72 mice were used for plasma PK study, where as 56 animals were used for brain PK study. For hemolysis assay, total 30 animals were used.
2. 2. Methods

2. 2. 1. Method of Development of Experimental LNLs

The experimental LNLs were prepared by conventional thin film hydration method with necessary modification of process parameters. For the formulation development, soya-L-α-lecithin (SL) was used as the main phospholipid. Along with that, we used DSPE and CHL. Briefly, weighed amount of LS, SL, CHL along with DSPE were dissolved in a required volume of chloroform taken in a 250 ml round bottom flask. To this mixture, BHA (2% w/v) was added as an antioxidant, since all phospholipids are generally sensitive to oxidation. The prepared mixture was then subjected to gentle rotation along with evaporation of the solvent in a rotary vacuum evaporator (Rotavap, PBU-6, Superfit, Mumbai, India), connected with a water bath. The temperature of the water bath was kept at 40 °C. After, evaporation of chloroform, a thin film was formed along the inner wall of the round bottom flask. The flask was then kept in a dessicator overnight, which caused further removal of any residues of organic solvent still left in the thin film. On day 2, the formed thin film was hydrated with phosphate buffer saline (PBS), pH 7.4 for about an hour at a rotation of 130 rpm. During this period, the formed film was completely dispersed in the PBS. Following hydration, the mixture was subjected to sonication in a bath-type sonicator (Trans-o-sonic, Mumbai, India). Sonication helps the reduction of large size vesicles into desired ultra small size range. After sonication, the formulation was allowed to stand for 1 h at room temperature followed by storage in a refrigerator overnight at 4 °C. On next day (day 3), the sample was subjected to cold centrifugation at 15,000 rpm for 45 minutes (Sigma Lab Centrifuge, UK). After centrifugation, the supernatant was discarded and the sediments were collected, which was stored at –20 °C overnight. The pre-cooled samples were then lyophilized for 10 h (laboratory lyophilizer, Kolkata, India) to obtain dry powdered formulation and stored in a refrigerator (4 °C).

2. 2. 2. Development of Fluorescent LNLs

For cellular uptake study, fluorescent LNLs were prepared with FITC. For this, FITC at a concentration 0.4% w/v was dissolved in a required volume of chloroform and ethanol mixture. From this stock preparation, about 50 µl was used added during the first step of preparation of LNLs. All other steps mentioned above remained unchanged.

2. 3. In vitro Studies of Experimental LNLs

2. 3. 1. Determination of Average Vesicle Diameter (Z-average) and Surface Potential

For the determination of mean vesicle diameter (Z-average), polydispersity index (PDI) and surface charge (zeta potential) of the experimental formulations, a weighed amount of the formulation was dispersed in milli-Q water, sonicated for 5 minutes and observed under a dynamic light scattering (DLS) instrument (DLS-nano ZS, Zetasizer, Malvern Instrument Ltd, UK). The data was interpreted by instrument software.

2. 3. 2. Percentage of Drug Loading and Loading Efficiency

For the calculation of amount of LS loaded in the experimental NLs, about 2 mg of the lyophilized LNLs was dissolved in required volume of acetonitrile. The sample was then sonicated in a bath sonicator for 10 min. After that, it was vortexed for another 3 min followed by centrifugation at 15,000 rpm. After centrifugation, the sediments were discarded and the absorbance of the collected supernatant was measured at 230 nm in UV-visible spectrophotometer (Advanced Microprocessor UV-Visible single beam, Intech 295, India). The amount of LS loaded in the experimental LNLs was calculated by applying following formula

\[
\% \text{ LS loading} = \frac{\text{Amount of LS in LNLs}}{\text{Amount of LNLs obtained}} \times 100
\]

\[
\% \text{ LS loading efficiency} = \frac{\text{Practical \% LS loading}}{\text{Theoretical \% LS loading}}
\]

2. 3. 3. Yield Percentage

To determine the % yield of each formulation batch, the fully dried LNLs obtained after lyophilization was weighed after each batch run. The % yield was calculated by applying following equation.

\[
\% \text{ Yield} = \frac{\text{Amount of LNLs obtained after lyophilization}}{\text{Total amount of all components used in the formulation batch}} \times 100
\]

2. 3. 4. Surface Morphology Study by Field Emission Scanning Electron Microscopy (FESEM)

To obtain surface morphology of the experimental formulation, electron microscope was used (JSM 6100, JEOL, Japan). For the experiment, lyophilized LNLs was spread on a carbon tape, fixed over a stub. Platinum coating was applied on the tested sample for 5 min with a voltage of 10 kV by means of a platinum coater. Finally the samples were observed under FESEM under liquid nitrogen conditions.

2. 3. 5. Cryo-Transmission Electron Microscopy (Cryo-TEM)

For Cryo-TEM analysis, weighed amount of lyophilized LNLs was dispersed in milli-Q water. The disper-
sion was vortexed in a cyclomixture for 5 min and a minute quantity of the dispersed LNLS (4 µl) was taken on a clean grid. The sample was then immediately vitrified in liquid ethane followed by storage in liquid nitrogen condition until imaging. Images of the sample was taken with the help of a electron microscope (Tecnai Polora, version 4.6, Netherlands) equipped with an FEI Eagle 4K x 4K charge-coupled device (CCD) camera. During imaging, vitreous grids were transferred into the electron microscope with the help of a cryostage. Throughout the experiment, the temperature of the samples was maintained –170 °C to observe the LNLS in their native form without any damage to the internal structure.

### 2.3.6. In vitro Drug Release Study

For the in vitro drug release study of the optimized LNLS, dialysis bag method was employed. The study was conducted at both pH 5 and pH 7.4. For the experiment, a weighed amount of lyophilized sample was dispersed in PBS pH 7.4 containing sodium lauryl sulfate as a solubilizing agent (release medium). The dispersion was put inside a dialysis bag. The two ends of the dialysis bag were tied with the thread and the whole system was immersed in a beaker containing 100 ml of the above release medium. After that, the beaker was placed on a magnetic stirrer at a rotation of 300 rpm using a magnetic bead. At various time intervals for 24 h, 1 ml of sample was withdrawn from the beaker with simultaneous replacement of the fresh release medium to maintain the sink condition. Similar procedure was followed for drug release study at pH 5. Each set was repeated in triplicate. The samples after collection were filtered with the help of membrane filter followed by measurement of the absorbance at 229 nm with the help of High performance liquid chromatography system.

### 2.3.7. Estimation of Drug Release Kinetics

Release kinetics helps to predict the mechanism of drug release from the experimental LNLS. For this, the data obtained from the in vitro drug release studies were fitted in various kinetic models. We determined the release pattern of LNLS in five different models such as zero order (cumulative value of time), Hixson–Crowell (cube root of percentage amount of drug remained to be released Vs time), first order (logarithmic value of cumulative amount of drug released Vs time), Higuchi (cumulative amount of drug released Vs square root of time), Korsmeyer–Peppas (logarithmic value of cumulative amount of drug released Vs logarithmic value of time), Hixson–Crowell (cube root of percentage drug remained to be released Vs time). The linearity of the calculated R2 values were assessed from the calculated R2 values.

### 2.3.8. Assessment of in vitro Cytotoxicity

The in vitro cytotoxic effect of the LNLS was tested by MTT assay on C6 rat glioma cells and the effect was compared to that of free LS suspension at equivalent drug concentrations. For the experiment, the tested cell line was cultured in Dulbecco’s modified eagle’s medium containing 10% fetal bovine serum in a 96 well culture plate and maintained inside a CO2-incubator at 37 °C. After attaining required density of cells in the plates (5 × 103 cells per well), the cells were treated with varying concentrations of LNLS, free drug suspension along with blank NLs (without drug). As negative control, few of the wells were treated with equivalent volumes of pure culture medium. After 48 h, media in each well was discarded and about 100 ml of MTT solution (1 mg/ml) was added to each well. The plate was kept inside CO2-incubator for another 4 h. After incubation, MTT solution was removed out of the well followed by addition of dimethyl sulfoxide (100 µl) in each well. Addition of dimethyl sulfoxide caused solubilization of formazan crystals to produce a purple color. The intensity of the color is related to the number of viable cells present after treatment in the well. The optical density was measured at 560 nm by micro plate reader (Spectra Max, Molecular Devices Corporation, Sunnyvale, USA). Percentage cell viability was evaluated by following formula

\[
\% \text{ cell viability} = \frac{\text{Optical density of the sample at 560 nm of treated cells}}{\text{Optical density of the sample at 560 nm of untreated cells}} \times 100
\]

### 2.3.9. Assessment of Internalization Efficiency

The internalization capacity of the selected fluorescent lipid nanostructures (FITC-LNLs) was tested on the C6 cells with the help of fluorescence microscopy. For the experiment, the cells were seeded in six-well culture plates and allowed to grow on cover slips at a density of 10 4 cells per well. The volume of cell culture was taken as 3 ml per well and incubated at 37 °C in CO2-incubator for 24 h. FITC-LNL was then added to the culture wells at two different subinhibitory concentrations of 50 ng/ml and 100 ng/ml. After 0.5 h, cover slips were taken out and carefully washed with PBS. The treated cells were fixed with 4% paraformaldehyde solution. Following fixation, the cells were washed twice with fresh PBS and stained with DAPI. Cover slips were dried and mounted on glass slide for imaging by a fluorescence microscope (Carl Zeiss, Oberkothen, Germany).

### 2.4. In vivo Studies

#### 2.4.1. Plasma and Brain Pharmacokinetic Studies

Drug PK profile was studied both in plasma and brain tissue in healthy Swiss albino mice (body weight 20–25 g). For the PK study, animals were divided into three groups. Group I animals were intravenously administered LS suspension as per dose. Group II animals were intravenously (i.v.) administered LNLS, containing LS equivalent to 6.5 mg/kg. Group III animals received sa-
line (control group). At each time point of sample collection in Group I and II, 3 animals were taken for both plasma and brain PK studies, where as for Group III (control group) 2 animals were taken for each time point of the study.

For the plasma PK study, post i.v. dosing, blood samples were collected from each set of animals at 0.5, 1, 2, 4, 6, 8, 10, 12, and 20 h intervals by heart puncture in heparinized tubes. A total number of 54 mice (27 each for Group I and II) were used in test groups and 18 mice were used for control groups. The blood samples were centrifuged using cold centrifuge at 5000 rpm for 10 min. Plasma was collected and stored at −40 °C till analysis.

For brain PK study, similar procedure as described above was followed. After i.v. injection, the animals were sacrificed at 0.5, 1, 2, 4, 8, 12 and 24 h intervals. Thus, a total number of 42 mice (21 each for Group I and II) were used in test groups where as 14 mice were used for the control group. Brains of each animal were removed. The whole brain was homogenized in a tissue homogenizer in PBS (pH 7.4). The homogenates were stored at −70 °C until further analysis.

For the determination of LS concentration in plasma samples, a Liquid chromatography with tandem mass spectrometry (LCMS/MS) technique was employed. The LCMS/MS Agilent C18 column was used. The mobile phase for the analysis was composed of acetonitrile, milli Q water along with formic acid (0.1%). The flow rate of mobile phase was kept as 0.4 ml/min. Sample volume for injection into chromatographic column was 20µl. The analyte was monitored using mass spectrometer equipped with a double quadruple along with electrospray ionization interface, operated in a positive mode (ESI+). To extract LS, samples were extracted with about three volume of methyl-tert-butyler ether. The mixture was then vortexed for 5 minutes followed by centrifugation at 3000 rpm for 10 min. After the process, the extracted LS present in the supernatant was collected. The organic solvent was allowed to dry under nitrogen atmosphere. For LCMS/MS analysis, the dried samples were then mixed in 100 ml of mobile phase (acetonitrile: water: formic acid). From the prepared stock, about 50 ml of reference standard solution was added in each sample. From the mixture, about 20 µl sample was injected into the LCMS/MS column (Agilent 6410, Triple Quad MS-MS, USA). The important PK parameters i.e. area under the curve (AUC), area under the first moment curve (AUMC), volume of distribution (Vd), mean residence time (MRT), total body clearance (Clt) etc. were determined using non-compartmental PK Solver software (Version 2.0).

2.4.2 Hemolysis Study

To check the biocompatibility and safety profile of the experimental lipid nanocarriers, hemolysis assay was carried out. For the study, blood samples were collected from Swiss albino mice. The samples were collected in pre-heparinized tubes, followed by centrifugation at 5000 rpm for 5–7 min. After that, the red blood cells (RBCs) were washed with PBS (pH 7.4). In a 96 well plate, a measured amount of RBC suspension (190 µl) was taken and treated with varying concentration of LNLs, free LS along with blank NLs (without drug). Double distilled water was used as the positive control. The samples were incubated for 1 h at 37 °C followed by centrifugation for 5 min at 5000 rpm to separate the un-lysed RBCs (as sediments). The supernatant was then taken and absorbance of the sample was measured at 570 nm. Percentage hemolysis was calculated as per the previously reported method.32

2.5. Statistical Analysis

All the experiments were carried out triplicate for accuracy and reproducibility. Data was expressed as the mean ± standard deviation (SD). One-way ANOVA was used to evaluate statistical followed by Tukey post hoc test with the help of Origin Pro 8 soft ware. Differences were considered statistically significant when p<0.05 at 95% confidence level.

3. Results

3.1. In vitro Studies

3.1.1. Formulation Optimization

By varying concentration of drug and lipids along with specific manufacturing parameters, we prepared several formulations. All the formulations were characterized

Table 1. Formulation components, % yield, % drug loading and % drug loading efficiency of selected experimental formulationsb

| Formulation code | SL:CHL:DSPE ratio (w/w) | Drug:Lipid ratio (w/w) | % yielda (%) | % drug loading (%) | % drug loading efficiency (%) |
|------------------|-------------------------|------------------------|--------------|-------------------|-----------------------------|
| LNL-1            | 50:50:8:1:2             | 58.3 ± 2.2             | 3.8 ± 1.4    | 57.8 ± 2.9        | 57.8 ± 2.9                  |
| LNL-2            | 225:75:8:1:5            | 76.6 ± 0.8             | 8.8 ± 1.5    | 87.4 ± 2.5        | 87.4 ± 2.5                  |
| LNL-3            | 250:50:8:1:10           | 63.5 ± 1.4             | 4.7 ± 0.8    | 69.3 ± 1.4        | 69.3 ± 1.4                  |

aData show mean ±SD (n =3). bAbbreviations: LNL, lomustine loaded lipid nanostructures; SL, soya-L-α-lecithin; CHL, cholesterol; DSPE, 1,2-distearoyl-sn-glycero-3-phosphatidylethanolamine

Satapathy et al.: Lomustine Incorporated Lipid Nanostructures...
by different in vitro techniques. Out of several formulations, here we report three formulations having desired in vitro properties (Table 1). We basically compared the formulations based on their drug loading capacity, % drug loading efficiency, as well as % yield. Out of the three, based on these characteristics, we finally selected LNL-2 as the optimized one for further works.

3.1.2. Determination of % Drug Loading, Loading Efficiency and Yield Percentage

The % drug loading for LNL-2 was 8.8 ± 1.5, whereas for LNL-1 and LNL-3, the values were 3.8 ± 1.4 and 4.7 ± 0.8 respectively. LNL-2 also showed higher loading efficiency (87.4 ± 2.5) and yield percentage (76.6 ± 0.8) than other two formulations (Table 1). Based on these parameters, we selected LNL-2 for all other studies.

3.1.3. Determination of Average Vesicle Diameter (Z-average) and Surface Potential

The diffraction light scattering (DLS) data revealed that the experimental formulations were below 100 nm size range. The optimized formulation (LNL-2) showed an average vesicle size of 83.41 ± 1.3 nm (Table 2). The PDI value of LNL-2 was 0.42 ± 0.06. Zeta potential of LNL-2 was found to be –56.7 mV (Table 2). The lower PDI value suggested a narrow size distribution pattern of the experimental formulation. Higher negative value of zeta potential was reported for the optimized formulation, which indicates the formulation would be stable in the suspension stage due to strong repulsive force between individual particles.

3.1.4. Surface Morphology Study by FESEM

The FESEM image of the LNL-2 was reported here, which was taken at 60,000x magnification scale (Figure 1A). The FESEM data demonstrated the smooth surface morphology of LNL-2. All vesicles were found spherical in shape and within 30–50 nm size range. Though out the sample, there were no signs of any lumps or formation of big agglomerates, which justifies the good formulation characteristics.

3.1.5. Cryo-transmission Electron Microscopy (Cryo-TEM)

Cryo-TEM analysis revealed the internal architecture of the formed vesicles. Image showed formation of unilamellar vesicles with intact lamellarity. Though, experimental NLs sample was found as polydisperse, i.e. both larger and smaller size vesicles were found, however all the vesicles were well below 50 nm as we desired. The larger size vesicle was around 40 nm, whereas smaller ones were around 25–30 nm as depicted in the photograph (Figure 1B). This was in good agreement with the data obtained from FESEM study. All the vesicles were found distinctive-ly spread throughout the diluted sample without any damage to their native internal structure.

### Table 2. Determination of Z-average, Poly dispersive index (PDI) and zeta potential of the selected formulation

| Formulation code | Z-average (dnm.)* | PDI  | Zeta potential (mV) |
|------------------|------------------|------|---------------------|
| LNL-2            | 83.41 ± 1.3      | 0.42 ± 0.06 | –56.7 |

*Data show mean ± SD (n = 3)
3. 1. 6. In vitro Drug Release Study and Analysis of Drug Release Kinetics

For the in vitro drug release study of the optimized formulation (LNL-2) at pH 5 and pH 7.4, dialysis method was employed. Result showed a pH dependent sustained drug release pattern over 48 h experimental time period at pH 5 and 7.4 (Fig. 2). Initially, though the drug release increased with time, but after 10 h, a more sustained release pattern was observed for the experimental formulation. However, amount of drug release was higher at pH 5 (endoctyotic vesicular pH). A cumulative amount of 82.34 ± 2.71% LS was released from LNL-2 at pH 5 over the experimental study period. To determine the nature of drug release from the experimental formulation, release data was fitted in different kinetic equations. From the respective graphs, corresponding R² values were calculated (Table 3). For LNL-2, among all the tested models, Koresmeyer–Pep- pas model demonstrated good linearity than other models (R² = 0.988).

3. 1. 7. Assessment of in vitro Cytotoxicity

In vitro cytotoxic or anti-proliferative effect of LNL-2 was evaluated in C6 rat glioma cells. MTT assay demonstrated a lower IC₅₀ (inhibitory concentration causing 50% of cell death) for LNL-2 as compared to free LS (Fig. 3). The plot of % cell viability against the tested dose (µg/ml) showed that with increase in concentration of both LNL-2 and free drug, the death rate of C6 cells increased. However, LNL-2 was found more effective (IC₅₀ 9.4 ± 0.8 µg/ml) as compared to free LS (IC₅₀ 23.8 ± 1.3 µg/ml) at equivalent drug concentration. The results further showed that blank LNLs (without drug) were almost non-toxic to the experimental C6 cell line even at the highest tested concentration (Fig. 3). Percentage of viable cells treated with blank LNLs was much higher compared to free LS, LNL-2, justifying non-toxic nature of ingredients used for the formulation.

3. 1. 8. Assessment of internalization Efficiency

To estimate whether the optimized formulation possesses the ability to permeate into the cancer cells or not, we tested in vitro internalization capacity of the fluorescent optimized formulation (FITC-LNL-2) at two different subinhibitory concentrations in C6 cells by fluorescence microscopy (Fig. 4). Fluorescent images of the cell line clearly showed preferential internalization of FITC-LNL-2 into the cells. The fluorescent formulation could successfully penetrate into cell and distributed throughout the cytoplasm. However, no nuclear permeation by the formulation was visualized. The nuclei of the cells were stained by DAPI, which distinctly visualized in the image and thus confirmed that FITC-LNL-2 could not cross the nucleus. A higher amount of internalization was observed in C6 cells at 100 ng/ml than the cells treated with 50 ng/ml during 0.5 h study period. Thus, a concentration dependent uptake was clearly noticed for the experimental formulation.

| Kinetic Model          | LNL-2            |
|------------------------|------------------|
| Zero Order Kinetics     | y = 2.430x + 7.537 |
|                        | R² = 0.786       |
| First Order Kinetics    | y = -0.014x + 1.221 |
|                        | R² = 0.923       |
| Koresmeyer Peppas       | y = 0.915x + 0.224 |
|                        | R² = 0.977       |

3. 2. In vivo Studies

3. 2. 1. Plasma Pharmacokinetics Study

PK study was carried out to detect LS at different time points in blood of the experimental mice. From plasma PK study, a reasonable difference was observed in the important PK parameters between LNL-2 and free LS treatments (Table 4). From the graph between plasma drug concentration Vs time, a prolonged blood residence time for LNL-2 was clearly observed than free LS (Fig. 5A). After 8 h, the concentration of LS from conventional suspension was not detectable; but LS encapsulated in LNLs showed a much sustained release of the drug and even detectable at 20 h (21.33 ng/ml ± 1.41). However, at 24h, the LS concentration dropped beyond threshold identification limit of LCMS/MS, and thus was non-identifiable. AUC₀₋∞ value was 7214.32 ± 311.41 ng h ml⁻¹ for free LS administration, whereas it was 12451.1 ± 234.16 ng h ml⁻¹ for LNL-2 administration. Similarly other important parameters like AUMC, MRT also showed preferential enhancements for LNL-2 as compared to free LS injection. MRT was increased almost three fold for LNL-2 treated animals (9.31 h) than the animals treated with free LS (3.64 h).

3. 2. 2. Brain Pharmacokinetics Study

Brain PK data showed increased brain availability of LS from LNL-2 than LS suspension (Fig. 5B). The AUC₀₋∞

| Pharmacokinetic Parameters | Plasma  | Brain  |
|----------------------------|---------|--------|
|                            | free LS | LNL-2  | free LS | LNL-2  |
| AUC₀₋∞ (ng h ml⁻¹)         | 7214.32 ± 311.41 | 12451.1 ± 234.16* | 3302.635 ± 138.6 | 15113.77 ± 221.4* |
| AUMC₀₋∞ (ng h² ml⁻¹)       | 31541.11 ± 1541.15 | 91322.42 ± 6561.25* | 41505 ± 231.66 | 87657 ± 172.62* |
| Cl (L h⁻¹)                 | 0.072 ± 0.04 | 0.211 ± 0.31 | 0.013 ± 0.06 | 0.531 ± 0.32* |
| MRT₀₋∞ (h)                | 3.64 ± 0.32 | 9.31 ± 0.22* | 5.61 ± 1.21 | 12.49 ± 3.21* |
| Vss (ml)                  | 0.039 ± 2.31 | 0.151 ± 0.13 | 2.431 ± 0.03 | 4.311 ± 1.76* |

*Data show mean ±SD (n = 6). AUC: area under the plasma concentration time curve; AUMC: area under the first moment curve; Cl: clearance; MRT: mean residence time; t₁/₂, plasma half life; Vss: steady state volume of distribution. * Data were significantly different (p < 0.05) where free LS and LNL-2 were compared. It was assessed by one-way analysis of variance (ANOVA) through Tukey-Kramer’s multiple comparisons test.

Satapathy et al.: Lomustine Incorporated Lipid Nanostructures ...
value of LS from selected formulation (LNL-2) (15113.77 ± 221.4 ng h ml⁻¹) was significantly higher than that from LS suspension (3302.63 ± 138.6 ng h ml⁻¹). A significant difference was also found in AUMC₀–∞ values in between LNL-2 and LS suspension treated groups (87657 ± 172.62 Vs 41505 ± 231.66). Data showed a higher volume of distribution and a lower rate of clearance (Cl) of drug from LNL-2 than that from LS suspension (Table 4). A 2.5 fold enhancement in the mean residence time of the drug in LNL-2 treated group was reported as compared to free LS treated group. Higher value of AUC, MRT, Vss along with lower value of Cl signifies higher bioavailability and prolonged retention of drug from LNL-2 in the brain tissue. Brain PK data further provided quantitative assessment of the superiority of the experimental formulation in crossing BBB than conventional free LS.

4. Discussion

The present study was intended to develop an optimized method for formulation of LS loaded NLs and to evaluate its potentiality in glioma cells. LS is a FDA approved established anticancer drug used for the treatment of different types of cancers including glioma. However it is associated with severe side effects like bone marrow depression along with shorter plasma half life. Thus, it is hypothesized that phospholipid based nanostructures may improve the delivery of LS to glioma cells and maintain desired therapeutic concentration in brain tissue over a period of time due to sustained drug release. Further, it would reduce the dose related severe toxicity of the conventional dosage forms. During product development, we found that specific formulation composition and critical in-process parameters have significant impact on the formation of nanosize LNLs and to produce desired in vitro properties. Initially we varied amount of SL, CHL (at a fixed LS concentration) to develop different batches of formulations and tested in vitro drug loading, loading efficiency, yield percentage etc. in each batch. However, amount of DSPE was kept constant. DSPE is the type of sphingo lipid, which is present abundantly in brain tissue. Thus, brain tissue-mimicking nature of DSPE is expected
to increase the accumulation and retention the experimental formulation in brain tissue. Reports from our previous work also ustified this hypothesis.\(^4\)

In the present work, percentage drug loading was initially increased with increase in the amount of drug. However, beyond certain amounts, percentage loading was not increased in direct proportion with the amount of drug. That indicates % drug loading was independent on amount of drug in the formulation. Thus, higher amount of drug does not guarantee higher drug loading in NLs. This was also in good agreement with the previous reports.\(^24,28\) Further, different process parameters, such as duration of hydration, temperature, sonication time, speed and time of centrifugation etc. affected the morphology, average vesicle size as well as drug loading capacity of the formulations. In our work, we have therefore standardized critical in-process parameters to obtain NLs with desired physicochemical properties. At a fixed ratio of 1:5 drug:lipid (w/w) along with specific manufacturing parameters such as 45 min hydration in PBS at 140 rpm, 40 min sonication in a bath type sonicator, 45 min ultra centrifugation at 15,000 rpm etc. the obtained formulation showed satisfactory characteristics in terms of % yield, % drug loading and loading efficiency and thus taken for further studies throughout the work.

The selected formulation (LNL-2) showed a satisfactory percentage of drug loading. For nanosize vesicular carriers, it has always been a problem to achieve higher drug loading. However, in our case, a reasonable drug loading of 8.8% was reported, which may be attributed to the standardized formulation composition and in-process parameters selected in our study.

The experimental lipid nanostructures (LNL-2) had a nanosize range as depicted from DLS study with a narrow distribution pattern. A lower PDI value of LNL-2 (0.42 ± 0.06) signifies homogenous distribution pattern of nanostructures in the formulation. It is known that smaller size nanodrug carriers remain suspended for a longer period of time as compared to larger size carriers, since the rate of sedimentation of suspended particles is mostly governed by stoke's law. According to stoke's law, rate of sedimentation of suspended particles are directly proportional to the diameter of the suspended particles. Again, a higher value of zeta potential on the experimental formulations (−56.7 mV) would help them to remain separated from each other due to higher repulsive force between individual vesicles. It has been reported that a zeta potential of more negative than −30 mV or more positive than +30 mV is taken as critical to form stable suspensions.\(^24,27\) Thus, in our case, ultra micron size (below 100 nm) and higher negative surface charge of selected formulation would help to form stable suspension.

FESEM images demonstrated smooth surface morphology, nanosize range (30–40 nm) and a clear homogenous nature of the experimental lipid nanostructures. It was observed that size of lyophilized LNL-2 found in the FE-SEM image was less than those detected by DLS method. It is because the DLS method mostly measures average hydrodynamic diameter of the vesicles in aqueous phase, whereas in FESEM dried powdered samples (lyophillized) are analysed. The formed vesicles while dispersed for a reasonable time period in milli Q water during sample preparation for DLS measurement might swell and increase in size than their native form. We found similar observations in some of the previous reports also.\(^24,25,31\) However, size of the sample observed by cryo-TEM was in good agreement with that of FESEM. Cryo-TEM method actually maintains the LNls in their native form where they are observed under liquid nitrogen environment. Thus, the delicate nature of lipid vesicles is well maintained in cryo-TEM method than normal TEM. In our study, cryo-TEM images showed intact bilayer of the formed vesicles without any damage to their native structure. We have taken experimental LNls at a diluted state so that the vesicles could be distinctively visualized. Cryo-TEM thus confirmed satisfactory production of LNls by the standardized process as well as maintenance of their internal architecture.

In vitro drug release study was carried out at physiological pH of blood (i.e. pH 7.4) as well as endocytotic vesicular pH (pH 5) to simulate different in vivo environments. Drug release though found to be sustained nature for both the pH, however, a higher cumulative percentage of drug was released at pH 5, than at pH 7.4. For both cases, initially, the amount of drug release was increased with time, but after 10 h, a more sustained release pattern was observed. A comparatively lower cumulative drug release at pH 7.4 signifies reduced loss of the drug at physiological condition and more specific to targeted site. As tumor microenvironment has reduced pH (pH 5–5.5) due to anaerobic respiration of malignant cells, higher drug release from the optimized formulation at pH 5 would enhance its therapeutic action at tumor area. Further, the sustained release behavior of the formulation would reduce dose, dosing frequency as well as associated toxic effects of LS. The pattern of drug release when fitted to different kinetics models, the formulation was best fitted with the Korsmeyer–Peppas kinetics model. Adherent to this model signifies that the drug release pattern from LNL-2 might follow complex mechanisms and include both diffusion and erosion. In case of the Korsmeyer–Peppas model, the fraction of drug release with time is generally represented as Mt/M∞ = Kt^n, where the release mechanism is governed by ‘n’.

The drug release is said to follow Fickian diffusion mechanism, when n ≤ 0.45. Similarly, when value of ‘n’ lies in between 0.45–0.89, the drug release is said to follow non-Fickian diffusion mechanism and when n remains ≥ 0.89, it is considered Case II (relaxational) transport.\(^28\) In our case, ‘n’ value was found as 0.724, which suggests that the drug release from LNL-2 might follow non-Fickian diffusion mechanism.

The in vitro cytotoxicity data demonstrated higher death rate of C6 cells treated with LNL-2 as compared to
free LS suspension at equivalent drug concentration. Data clearly revealed better antitumor efficacy of the tested formulation than free drug. LS delivered through LNLs was more cytotoxic to the glioma cells with lower IC\text{50} value (9.4 μg/ml) as compared to free LS (23.8 μg/ml). The blank formulation (without drug) showed no significant impact on the cell death rate even at highest tested concentrations. Clearly, it suggests the biocompatible and non-toxic nature of excipients used in the formulation development, which is a good sign for in vivo applications.

In order to visualize the internalization of LNL-2 by C6 cells, FITC was used as a fluorescent marker. The FITC-LNL-2 produced green fluorescence while visualized under fluorescence microscope. Further, DAPI was used as coloring agent to stain nucleus, which produces blue fluorescence. In the study, we have chosen two different concentrations of the LNL-2, which are subinhibitory concentrations, i.e. quite less than the reported IC\text{50} value. Thus, at these concentrations, no damage to the normal cellular architecture could be there and the cells were visualized in their native form. Confocal images depicted a preferential uptake of FITC-LNL-2 by C6 cells. The formulation was predominantly spread throughout the cytoplasm, around the nucleus. Higher cellular internalization of the optimized formulation could be attributed to the ultra micron size range. It may be possible that due to much smaller size as well as higher lipophilic property, the experimental LNls could sufficiently permeate through the cancer cells, which is again a good finding towards successful application of the experimental formulation for the treatment of glioma.

The PK parameters of LNL-2 treated mice demonstrated a higher value of AUC, AUMC, V\text{ss}, and MRT in comparison to animals treated with free LS suspension. The plasma drug concentration for LNL-2 treated group at 24 h was reasonably higher than that of LS treated groups. The drug concentration for free LS treated groups was not detectable after 10 h, since it dropped beyond the minimum detectable limit (10ng/ml) of our LCMS/MS system, whereas LS from LNL-2 showed its presence up to 20 h study period. The data justified the potential of the optimized formulation to remain circulated for prolonged period of time in blood. Further, due to longer blood residence profile, the formulation would get sufficient time to reach into brain tissue by crossing BBB. Owing to its extreme small size, and higher negative surface charge, the experimental LNls might escape from the trap of reticuloendothelial cells successfully and could maintain a longer presence in blood.

A similar observation was found in case of brain PK parameters in mice treated with LNLV-2/free LS. The LS incorporated in lipid nanostructures showed a much sustained release up to 24 h than LS suspension. Initially, LS concentration was higher in case of plain suspension than LNL-2. Interestingly, at 2 h post i.v. injection, drug concentration was almost similar for both LNL-2 and free LS suspension. However, after 4 h, drug level was drastically reduced in case of free LS, whereas it dropped in a much controlled manner for LSNL-2 till 24 h of study period. After 10h, the drug level from free LS reduced beyond the threshold limit of detection of LCMS/MS and thus could not be detected. Even at 24 h, 13.76 ng/ml of drug was detected from LNL-2, which signifies the sustained release and prolonged residence time of LNL-2 in brain tissue. The significant enhancements in AUC and AUMC in the LNL-2 treated group signified higher bioavailability of the drug from LNL-2 than free LS. Brain PK results further confirmed the potentiality of optimized lipid nanostructures to cross BBB and enter into brain for a reasonable time period, which is very crucial data for successful in vivo applications in glioma.

Though application of LS for the treatment of brain and intracranial tumors are not new, but development of novel strategies to enhance its efficacy and to reduce the associated toxic effects have been tried in recent times only. Funmilola A. F. et al., 2016 reported the development of LS loaded nanoparticles for improved brain delivery and to check the dose-related myelosuppression. The in vivo efficacy of the selected LS loaded nanoparticles was assessed in orthotopic U87 MG glioblastoma animal model. Results showed that LS delivered through nanoparticle system improved the survival of intracranial tumour bearing mice and also did not produce no additional myelosuppressive effects. Another work reported by Salman J. et al showed efficacy of LS loaded superparamagnetic iron oxide nanoparticles on U87 MG cancer cell line. The encapsulation efficiency for the LS loaded nanoformulation was 46 ± 6.8%. The experimental nanostructures were found cytotoxic on U87 MG cancer cells at concentration above 100 μg/mL. Further, they did not report PK studies or any other related animal experiments to justify the suitability of the experimental nanoparticle formulations for in vivo applications.

We must say that the present work will be quite different from all such reported works, since till now LS loaded LNls have not been evaluated for their in vitro efficacy on C6 glioma cells. Further, no study has been reported so far both the plasma and brain PK profile of LS encapsulated in LNls. Hemolysis assay further adds novelty to the work. The simple formulation technique used for the study along with clear optimization of critical manufacturing parameters would be beneficial for furthering its research towards technology transfer. Higher encapsulation efficiency of the optimized formulation adds value to the work. Overall the data presented in FESEM, cryo-TEM, confocal microscopy, PK profile etc. stands unique in their parts.

For the desired in vivo applications, blood compatibility of the nanodrug formulations is an essential criterion. Hemolysis assay of the selected formulation in the experimental mice RBCs depicted an excellent blood compatibility nature of LNL-2 since a very low hemolysis (up to 7.1%) was observed for the optimized formulation even...
at highest tested concentration. The haemolytic effect for the free LS was also less than LNL-2. From the negligible hemolysis activity, it may be concluded that LNL-2 could be employed as a safe, non-toxic and effective nanocarrier platform for its future clinical investigations.

5. Conclusion

The study reported an optimized and easily controllable method for the development of lipid based nanostructures for sustained delivery of LS for the treatment of glioma. The selected formulation (LNL-2) showed a preferable nanosize (within 50 nm) as depicted from FESEM and cryo-TEM study. A reasonable drug loading (8.8%) was reported for LNL-2 along with a sustained in vitro drug release profile during a 48 h study period. Owing to its ultra small size and high lipophilic nature, LNL-2 showed preferential internalization in C6 glioma cells. MTT assay showed a higher toxicity of LNL-2 on the tested cancer cells than free LS. The formulation showed improved PK profile both in blood and brain in experimental mice models than free drug suspension. A higher mean residence time of LNL-2 in blood signifies its higher in vivo stability. Significant increase in important brain PK parameters like AUC and MRT for LNL-2 justified its higher bioavailability and prolonged retention in brain tissue. Further negligible hemolysis in mice RBCs justified the non-toxic and biocompatible nature of LNL-2 for safe in vivo application. The formulation development steps were simple and well standardized, which would be helpful during technology transfer. Results of the study overall suggest the potential application of LNL-2 for sustained delivery of LS for glioma treatment. However, further in vivo testing on various pharmacological and toxicological aspects of LNL-2 is warranted for its future clinical application.

Povzetek

Učinkovito zdravljenje gliomov v medicini še vedno predstavlja izziv. Namen dela je izdelati in ovrednotiti nanostrukture na osnovi lipidov za izboljšano dostavo lomustina v možganske tumorske celice. Poskusne formulacije (LNL) so bile razvite s spremenjeno tehniko hidracije lipidne plasti in njihove značilnosti ovrednotene z in vitro metodami, ki vključujejo analizo velikosti delcev, površinskega naboja, površinske morfologije, notranje strukture, in vitro nalaganja učinkovine, profil sproščanja učinkovine itd. Protirakavi potencial je bil testiran in vitro na glioma celični liniji C6. Elektronsko-mikroskopska študija je prikazala velikost manj kot 50 nm za izbrane LNL pri 8.8 % vključitvi učinkovine s težnjo po podaljšanem sproščanju učinkovine v obdobju 48 h. Konfokalna mikroskopija je pokazala obsežno internalizacijo izbranih LNL v celice C6. S testom MTT je bilo ugotovljeno, da so LNL bolj citotoksični kot prosta učinkovina in prazni nanonosilci. Izbrani LNL so izkazovali izboljšan farmakokinetični profil v krvi in možganih pri poskusnih modelih miši skupaj z zanemarljivim hemolizo mišjih krvnih celic. Za prenos LNL v klinično uporabo so v prihodnosti upravičene nadaljnje študije.
