Abstract

A Lie algebraic approach to the unitary transformations in Weyl quantization is discussed. This approach, being formally equivalent to the $\star$-quantization is an extension of the classical Poisson-Lie formalism which can be used as an efficient tool in the quantum phase space transformation theory.

The purpose of this paper is to show that the Weyl correspondence in the quantum phase space can be presented in a quantum Lie algebraic perspective which in some sense derives analogies from the Lie algebraic approach to classical transformations and Hamiltonian vector fields. In the classical case transformations of functions $f(z)$ of the phase space $z = (p, q)$ are generated by the generating functions $G_\mu(z)$. If the generating functions are elements of a set, then this set usually contains a subset closed under the action the Poisson Bracket (PB), so defining an algebra. To be more precise one talks about different representations of the generators and of the phase space algebras. The second well known representation is the so called adjoint representation of the Poisson algebra of the $G_\mu$’s in terms of the classical Lie generators $L_{G_\mu}$ over the Lie algebra. These are the Hamiltonian vector fields with the Hamiltonians $G_\mu$. By Liouville’s theorem, they characterize an incompressible and covariant phase space flow.

The quantum Lie approach can be based on a parallelism with the classical one above. In this case the unitary transformations are represented by a set of quantum generating functions $A_\mu(z)$ which are the quantum partners of the $G_\mu$’s. The non commutativity is encoded in a new multiplication rule, i.e. $\star$-product in $z$. The quantum Lie generators $\hat{V}_{A_\mu}$ over the Lie bracket are the adjoint representations of the generating functions $A_\mu(z)$ over the Moyal bracket and they correspond to quantum counterparts of the classical Hamiltonian vector fields $L_{G_\mu}$. They are represented by an infinite number of phase space derivatives. The only exception is the generators of linear canonical transformations defining the $sp_2(\mathbb{R})$ sub algebra. In this case the generators are given by the classical Hamiltonian vector fields generated by quadratic Hamiltonians and the classical and quantum generators are identical [see (46) below].

The classical Lie approach is sometimes referred to as the Poisson-Lie theory (PLT). This terminology is quite appropriate for generalizations as the algebraic representations that are relevant are written by using the Poisson and Lie product rules. For a similar reason we suggest that the quantum approach be referred to as the Moyal-Lie theory (MLT).
In section 1 we start with a brief textbook discussion of the PLT. The Lie algebraic treatment of the quantum transformation theory starts in section 2 with a discussion of Weyl correspondence (section 2.1) and the $\star$-product. The main results of this paper, the MLT and the $\star$-covariance are discussed at length in section 2.2. The associativity property is discussed comparatively with respect to Poisson-Lie and the Moyal-Lie algebras in section 3. In the light of the classical covariance versus $\star$-covariance of the phase space trajectories under canonical transformations the time evolution deserves a specific attention. The time evolution in the MLT and its extended $\star$-covariance property is examined in section 4. Finally, we discuss the equivalence of the MLT to the standard $\star$-quantization through the $\star$-exponentiation in section 5.

A. The Poisson-Lie Theory and the classical phase space

The classical Lie generators $L_{G^\mu}$ are given by

$$L_{G^\mu} = (\partial_z G^\mu)^T J \partial_z,$$  \hspace{1cm} (1)

where $G^\mu = G^\mu(z)$’s are in the set of phase space functions (generating functions) where $\mu = 1, \ldots, N$ describes the generator index, $N$ being the total number of generators, $z$ denotes the $2n$ dimensional phase space row vector $z = (z_1, \ldots, z_{2n}) = (q_1, \ldots, q_n; p_1, \ldots, p_n)$, $\partial_z = (\partial z_1, \ldots, \partial z_{2n})$. $T$ is the transpose of a row vector, and $J$ is the $2n \times 2n$ symplectic matrix with elements $(J)_{ij}$, $i, j = (1, \ldots, 2n)$

$$(J)_{ij} = \begin{cases} 1 & \text{if } j = i + n \\ -1 & \text{if } i = j + n \\ 0 & \text{all other cases} \end{cases}.$$  \hspace{1cm} (2)

The classical algebra of the phase space generating functions is defined over the Poisson bracket (PB)

$$\{G^\mu, G^\nu\}^{(P)} = (\partial_z G^\mu)^T J (\partial_z G^\nu)$$  \hspace{1cm} (3)

and that of the generators $L_{G^\mu}$ over the Lie Bracket (LB)

$$[L_{G^\mu}, L_{G^\nu}] \equiv L_{G^\mu} L_{G^\nu} - L_{G^\nu} L_{G^\mu} = L_{(G^\mu, G^\nu)^{(P)}}$$  \hspace{1cm} (4)

where the LB is defined by the first equality.

A classical canonical transformation (CCT) is considered to be a symplectic phase space map $M_\bar{\varepsilon} : z \mapsto Z_\varepsilon(z)$ with $Z = (Q_1, \ldots, Q_n; P_1, \ldots, P_n)$ describing the new set of canonical phase space pairs. The symplectic condition is the invariance of the PB given by

$$\{z_j, z_k\}^{(P)} = \{Z_j, Z_k\}^{(P)} = J_{jk}$$  \hspace{1cm} (5)

which implies that $M_\varepsilon$ is invertible. If the symplectic map is continuously connected to the identity within a domain $\varepsilon = 0$, i.e. $M_{\varepsilon=0} = I$, Lie’s first theorem states that the first order infinitesimal change in $z_j$ is

$$\delta_j(z, \delta \varepsilon^{(1)}) = \delta \varepsilon^\mu L_{G^\mu} z_j.$$  \hspace{1cm} (6)
where a summation over the generating function index \( \mu \) is assumed. Finite canonical transformations can be obtained by infinitely iterating Eq. (6) to an exponential operator as

\[
Z_j = \exp \{ \epsilon_{\mu} L_{G_{\mu}} \} z_j
\]  

and following \([L_{G_{\mu_k}}, f] = \{G_{\mu_k}, f\}^{(P)}\) and considering \( f = z_j \),

\[
Z_j = z_j + \epsilon_{\mu} \{G_{\mu}, z_j\}^{(P)} + \frac{1}{2!} \epsilon_{\mu_1} \epsilon_{\mu_2} \{G_{\mu_1}, \{G_{\mu_2}, z_j\}\}^{(P)} + \ldots
\]

\[
+ \frac{1}{k!} \epsilon_{\mu_1} \ldots \epsilon_{\mu_k} \{G_{\mu_1}, \ldots, \{G_{\mu_k}, z_j\}\}^{(P)} + \ldots
\]  

where summations over the repeated indices are assumed. Let us consider the case \( N = 1 \). This allows us to simplify the notation and drop the index \( \mu \). In fact, the generalization for finite \( N \) is nontrivial because of the possibility of additional structures in the Poisson algebra, for instance, PB of the generators \( G_{\mu} \), where \( \mu = 1, \ldots, N \), may be closed under a specific algebra with \( N \) generators. For what we present here such algebraic generalizations will not be needed. It can be shown that, if \( f(z) \) has a convergent Taylor expansion in powers of \( z \) in some domain \( z \in D \), the transformation of \( f \) is

\[
f(Z) = \exp \{ \epsilon L_G \} f(z) \exp \{-\epsilon L_G\}
\]  

where it is to be noted that Eq. (9) is an operator relation, i.e. it can be multiplied on the left and/or right by any arbitrary function \( g(z) \) without changing its validity. The transformed variable \( Z \) and \( f(Z) \) must also be well defined in the same domain \( D \). From Eq. (9) it follows the remarkable manifest covariance property

\[
[\exp \{ \epsilon L_G \} f](z) \equiv f_\epsilon(z) = f(\exp \{ \epsilon L_G \} z) = f(Z(\epsilon, z)),
\]  

and the generalized Leibniz rule

\[
\exp \{ \epsilon L_G \} [f(z) g(z)] = [\exp \{ \epsilon L_G \} f] [\exp \{ \epsilon L_G \} g] = f(Z) g(Z)
\]  

which can be summarized in

\[
\exp \{ \epsilon L_G \} [f(z) \ldots] = [\exp \{ \epsilon L_G \} f(z)] [\exp \{ \epsilon L_G \} \ldots] = f(Z) [\exp \{ \epsilon L_G \} \ldots].
\]  

In Eq’s (10-12) the square brackets indicate that the operator on the left acts on the object within the brackets only. In (12) the dots indicate the possibility of further functions to be acted upon. Although Eq’s (10-12) are different ways of writing Eq. (9) we will keep them explicitly for that they facilitate a comparison with their quantum analogs.

The MLT is a generalization of the Poisson-Lie theory to the noncommutative phase space. It will be shown that, the Moyal-Lie generators can be uniquely derived in the quantum case with similar covariance properties when the role of the ordinary functional product is taken by the \( \star \)-product. As it turns out, the manifest covariance property in Eq. (10) is modified because of the non commutativity of the \( \star \)-product. As opposed to the standard covariance in (10) under ordinary multiplication the new covariance rule is manifest under the \( \star \)-multiplication of the functions of the phase space. The classical covariance is then recovered in the \( \hbar \to 0 \) limit of the \( \star \)-covariance.
B. Quantum Lie generators

The quantum mechanical results presented here are corollaries of a recent work of one of the present authors on the extended covariance in non commutative phase space under canonical transformations. Our formulation here is based on Weyl correspondence as a consistent and analytic principle between the classical and the quantum phase spaces.

1. The Weyl correspondence

Let \( \hat{z} = (\hat{z}_1, \ldots, \hat{z}_{2n}) = (\hat{q}_1, \ldots, \hat{q}_n; \hat{p}_1, \ldots, \hat{p}_n) \) describe the phase space operators satisfying, as usual, \([\hat{z}_i, \hat{z}_j] = i\hbar J_{ij}\) and zero for all other Lie Brackets (commutators). We adopt the same definitions for \( z \) and \( \partial z \) as in the classical case. The Weyl map is a correspondence rule between the operators described by \( \hat{F} = F(\hat{z}) \) and the functions \( f(z) \) denoted by \( \hat{F} \leftrightarrow f \)

and expressed as

\[
\hat{F} = \int d\mu(z) f(z) \hat{\Delta}(z), \quad f(z) = Tr\{\hat{F} \hat{\Delta}(z)\}
\]

where \( d\mu(z) = \prod_{k=1}^n [dq_k dp_k/(2\pi\hbar)] \). We adopt the same definitions for \( z \) and \( \partial z \) as in the classical case. Here \( \hat{\Delta}(z) \) describes a mixed basis for operators and functions in the phase space given by

\[
\hat{\Delta}(z) = \int d\mu(\omega) e^{-i\omega J z/\hbar} e^{i\omega J \hat{\Delta}/\hbar}
\]

where \( \omega = (\omega_1, \ldots, \omega_{2n}) \) is in the same domain as \( z \), i.e. \( \mathbb{R}^{2n} \), \( d\mu(\omega) = \prod_{k=1}^n [d\omega_k d\omega_{k+n}/(2\pi\hbar)] \). For details on the properties of the continuous \( \hat{\Delta}(z) \) basis we refer the reader to Ref. [4].

At a fundamental level the Weyl correspondence can be stated as

\[
e^{i(\omega J z)/\hbar} \leftrightarrow e^{i(\omega J z)/\hbar}
\]

for all real \( \omega \). From Eq. (15) the association for the identity, i.e. \( \mathbb{I} \leftrightarrow 1 \) is unique for \( \omega = 0 \). All other maps between the operators and the functions in the Hilbert space are derived from Eq. (15) by suitable differential operations. Eq. (15) is an explicit rule which leaves the algebraic properties of operators in the phase space invariant. Let \( \hat{F} \leftrightarrow f \) and \( \hat{G} \leftrightarrow g \) be associated by the Weyl correspondence. Then

\[
\hat{F} \hat{G} \leftrightarrow f \star g = f e^{i(\hat{\Delta} \to \partial z)} \hat{G} \quad (16)
\]

where \( \star \) is a non commutative, i.e. \( f \star g - g \star f \neq 0 \), and associative, i.e. \( f \star (g \star h) = (f \star g) \star h \) operation corresponding to the phase space symbol of the operator product. One way to define the \( \star \) product is by its action explicitly on the functions of the phase space by

\[
f \star = f(z + \frac{i\hbar}{2} J \to \partial z), \quad \star f = f(z - \frac{i\hbar}{2} J \to \partial z)
\]

(17)

where the arrows indicate the action of the derivatives. We explicitly write the correspondence for the LB as
\[ [\hat{F}, \hat{G}] \Leftrightarrow f \star g - g \star f = \{f, g\}^{(M)} \]  
(18)

where the superscript \( M \) denotes the Moyal Bracket (MB) defined by the well-known expression

\[ \{f, g\}^{(M)} = i\hbar \{f, g\}^{(P)} + \mathcal{O}(\hbar^k, \partial_z^{(k)}) \big|_{3 \leq k} . \]  
(19)

The first term is \( i\hbar \) times the PB as defined in Eq. (3). \( \mathcal{O}(\hbar^3, \partial_z^{(3)}) \) represents higher order terms which appear in infinitely odd powers of both \( \hbar \) and \( \partial_z \).

2. The Unitary transformations in phase space and quantum Lie generators

All invertible transformations (including non-unitary ones) can be formalized in the quantum phase space. In this paper we will only consider the unitary ones. Let \( \hat{F} \) be an operator and \( \hat{U}_A = e^{i\gamma A} \) a one parameter unitary transformation with \( \gamma \in \mathbb{R} \). In the following we prove that the unitary transformation of \( \hat{F} \) by \( \hat{U}_A \) in the operator space has a unique representation in the phase space given by

\[ \hat{F}' = \hat{U}_A^\dagger \hat{F} \hat{U}_A \Leftrightarrow f'(z) = e^{i\gamma \hat{V}_A} f(z) \]  
(20)

where, \( \hat{F} \Leftrightarrow f, \hat{F}' \Leftrightarrow f' \) as usual, and \( \hat{V}_A \) is a nonlinear and Hermitian generator associated with a real phase space generating function \( A(z) \) by \( \hat{V}_A = A \star - \star A \).

Since \( \hat{A} \) is considered to be Hermitian, it can be represented in a symmetrically ordered series in \( \hat{z} \) as,

\[ \hat{A} = A(\hat{z}) = \sum_{n,m,r} a_{n,m,r} \hat{p}^n \hat{q}^m \hat{p}^r \]  
(21)

where \( a_{n,m,r} \) are some real coefficients and we indicated the \( \hat{p}, \hat{q} \) dependence explicitly for clarity. In order to prove Eq. (20) we start with

\[ \hat{F}' = \hat{F} - i\gamma [\hat{A}, \hat{F}] + \ldots + \frac{(-i\gamma)^k}{k!} \left[ \hat{A}, \ldots, [\hat{A}, \hat{F}], \ldots \right] \]  
(22)

and calculate the commutator in the \( \mathcal{O}(\gamma) \) term. We use a particular phase space representation of \( \hat{z} \) known as the Bopp shifts and given by

\[ \hat{z}_L = \left( \hat{\rho}_L, \hat{\eta}_L \right) = \left( p + \frac{i\hbar}{2} \hat{\partial}_\eta, q + \frac{i\hbar}{2} \hat{\partial}_p \right), \quad \hat{z}_R = \left( \hat{\rho}_R, \hat{\eta}_R \right) = \left( p - \frac{i\hbar}{2} \hat{\partial}_\eta, q - \frac{i\hbar}{2} \hat{\partial}_p \right). \]  
(24)

It is readily verified that
\[ [\hat{z}_{JL}, \hat{z}_{kR}] = 0, \quad [\hat{z}_{JL}, \hat{z}_{kL}] = i\hbar J_{j_k} = [\hat{z}_{kR}, \hat{z}_{jR}] \, . \quad (25) \]

By repeatedly applying Eq’s (23) to the commutator of Eq. (21) with \( \hat{\Delta} \), one explicitly obtains

\[ [\hat{A}, \hat{\Delta}] = \hat{V}_A \hat{\Delta}, \quad \hat{V}_A = \sum_{n,m,r} a_{n,m,r} \left\{ \hat{P}_L^m \hat{q}_L^n \hat{P}_R^n \hat{q}_R^m \hat{P}_L^r \hat{q}_R^r \right\} . \quad (26) \]

Remembering that \( \hat{A} \) in Eq. (21) is symmetrically ordered, Eq. (24) implies for an arbitrary phase space function \( f(z) \)

\[ \hat{V}_A f = [\mathcal{A}(\hat{z}_L) - \mathcal{A}(\hat{z}_R)] f = \mathcal{A} * f - f * \mathcal{A} = \{ \mathcal{A}, f \}^{(M)} \, . \quad (27) \]

where Eq. (17) is used in the last part. Note that \( \hat{V}_A \) is an operator, composed of powers of \( z, \partial_z \) in the same way as \( \hat{A} \) depends on the Bopp operators \( \hat{z}_{L,R} \), reproducing the action of the commutator \( [\hat{A}, \hat{\Delta}] \) in the phase space. By recursive application of (26) the \( k \)’th order commutator in Eq. (22) is represented by

\[ [\hat{A}, \ldots, [\hat{A}, \hat{\Delta}], \ldots] = (\hat{V}_A)^k \hat{\Delta}, \quad \text{for all } 0 \leq k \, . \quad (28) \]

Exponentiating Eq. (28)

\[ \hat{U}_A^\dagger \hat{\Delta} \hat{U}_A = e^{-i\gamma \hat{V}_A \hat{\Delta}} . \quad (29) \]

We now use this result in the second equation in (13) for \( \hat{F}' \Leftrightarrow f' \)

\[ f'(z) = Tr\{ \hat{F}' \hat{\Delta} \} = Tr\{ \hat{U}_A^\dagger \hat{F} \hat{U}_A \hat{\Delta} \} = Tr\{ \hat{F} \hat{U}_A \hat{\Delta} \hat{U}_A^\dagger \} = e^{i\gamma \hat{V}_A} f(z) \, . \quad (30) \]

producing the correspondence in (20). Note that the unitary transformation of \( \hat{F} \) involves left and right multiplications by the transformation operator \( \hat{U}_A \) and its conjugate. Because of the underlying associativity these operations commute. The same is observed also with the exponential phase space operator in Eq. (30). Using Eq. (27) we write

\[ e^{i\gamma \hat{V}_A} = e^{i\gamma \{ \mathcal{A}((\hat{z}_L) - \mathcal{A}(\hat{z}_R)) \} = e^{i\gamma \mathcal{A}(\hat{z}_L)} e^{-i\gamma \mathcal{A}(\hat{z}_R)} e^{i\gamma \mathcal{A}(\hat{z}_L)} = e^{i\gamma \mathcal{A}(\hat{z}_R)} e^{-i\gamma \mathcal{A}(\hat{z}_L)} . \quad (31) \]

Eq. (30) is the simplest form of a canonical transformation acting on the functions of the phase space. Using Eq’s (17) and (27) it can be put in the form

\[ e^{i\gamma \hat{V}_A} f = e^{i\gamma \{ \mathcal{A}(\hat{z}_L) - \mathcal{A}(\hat{z}_R) \} f} = f + i\gamma (\mathcal{A} * f - f * \mathcal{A}) + \frac{(i\gamma)^2}{2!} (\mathcal{A} * \mathcal{A} * f + f * \mathcal{A} * \mathcal{A} - 2\mathcal{A} * f * \mathcal{A}) + \ldots = f + i\gamma \{ \mathcal{A}, f \}^{(M)} + \frac{(i\gamma)^2}{2!} \{ \mathcal{A}, \{ \mathcal{A}, f \} \} + \ldots + \frac{(i\gamma)^k}{k!} \{ \mathcal{A}, \ldots, \{ \mathcal{A}, f \} \ldots \} + \ldots = e^{i\gamma (\mathcal{A} * f)} f e^{-i\gamma (\mathcal{A} * f)} \, . \quad (32) \]

which can also be deduced from (31) using (24).

There is a unique correspondence between \( \hat{V}_A \) and the unitary transformation \( \hat{U}_A \) that it represents as illustrated by

6
\[
\begin{align*}
\left( e^{i\gamma V_A} f \right) \overset{Weyl}{\leftrightarrow} \hat{f} \\
\left( e^{i\gamma V_A} f \right) \overset{Weyl}{\leftrightarrow} \hat{f} \\
\left( e^{i\gamma V_A} f \right) \overset{Weyl}{\leftrightarrow} \hat{f} \\
\end{align*}
\]

In particular, if we consider two such transformations acting on the phase space, denoting the correspondence by \( A_1 \leftrightarrow \hat{V}_{A_1} \) and similarly for \( A_2 \), we find

\[
[\hat{V}_{A_1}, \hat{V}_{A_2}] = \hat{V}_{\{A_1, A_2\}(M)}.
\]

Furthermore, if the operators \( \hat{A}_k \) are the generators of an abstract Lie algebra the corresponding phase space operators \( \hat{V}_{A_k} \) generate the adjoint representation in the phase space of the same Lie algebra.

It is clear that \( \hat{V}_{A_k} \)'s are quantum analogs of the classical Lie generators \( L_{\hat{g}_k} \) of classical canonical transformations. To demonstrate this we examine the quantum analog of the classical covariance property in Eq. (9-10). Since the analog of \( M_\epsilon \) is the exponentiated generator in Eq. (30) we start with that equation. Using the correspondence in Eq. (16) we find

\[
\left( e^{i\gamma V_A} f \right) \ast \left( e^{i\gamma V_A} g \right) = \left( e^{i\gamma V_A} f \right) \ast \left( e^{i\gamma V_A} g \right).
\]

where the square brackets have the same role as in (10)-(12). Considering (36) for arbitrary \( g \) the analog of Eq. (12) is found as

\[
\left( e^{i\gamma V_A} f \right) \ast \left( e^{i\gamma V_A} g \right) = \left( e^{i\gamma V_A} f \right) \ast \left( e^{i\gamma V_A} g \right).
\]

Eq. (37) is converted into

\[
f' \ast = e^{i\gamma V_A} f \ast e^{-i\gamma V_A}
\]

which is the quantum analog of Eq. (3). We now examine the covariance properties under the action of \( e^{-i\gamma \hat{V}_A} \) in analogy with Eq. (40). Suppose that \( f(z) \) is expanded in terms of binomials \( p^m q^n \) as

\[
f(z) = \sum_{0 \leq (m,n)} f_{m,n} \ p^m q^n
\]

We use in (39) the fact that \( p^{n+m} = p^n \ p^m = [p^n \ast p^m] \) for all \( m, n \) and similarly for powers of \( q \). Hence \( f \) in Eq. (39) is equivalently expressed as

\[
f(p, q) = \sum_{0 \leq (m,n)} f_{m,n} \left[ p \ast \ldots \ast p \right] \left[ q \ast \ldots \ast q \right].
\]

Note that, in (40), the ordinary product is neither commutative nor associative with the \( \ast \)-product. It can now be checked by using Eq’s (30) and (38) that classical covariance described by Eq. (10) is violated.
\[ f' = [e^{i\gamma} \hat{V}_A f](z) \neq f(Z) \]  
(41)

where \( Z = Z(z) \) are the new canonical coordinates given by

\[ Z = [i^{\gamma} \hat{V}_A z]. \]  
(42)

We now trace back to the origin of the violation of the classical covariance in Eq. (11). To illustrate the point we adopt two distinct and simple cases. As the first example let us consider \( f = pq \). Our goal is to look for what causes the effect \( f' \neq PQ \). By using the properties of the \( \ast \)-product we first write \( f = p \ast_q g + ih/2 \). We now apply the transformation in Eq. (30). By Eq’s (35-38) we find \( f' = P \ast_q Q + ih/2 \). The only way in which \( pq \mapsto PQ \) under all such transformations as in (42) is when \( \ast_q = \ast_{Q,P} \). If this was true the covariance would have been manifest, since we would have had \( P \ast_q Q = P \ast_{Q,P} Q = PQ - ih/2 \). Then inserting this in \( f' \), we would have found \( f' = PQ \). As the second example we consider \( f(p, q) = p^2 = [p \ast p] \). Repeating the same calculation here we find that \( f' = P \ast_q p \neq P^2 \). The equality, which indicates covariance, would have been obtained for all transformations \( Q = Q(z) \) and \( P = P(z) \) if and only if \( \ast_q = \ast_{Q,P} \).

These two typical examples demonstrate that the very intrinsic property of the \( \ast \) operation, non invariance under a general canonical transformation, i.e. \( \ast_q \neq \ast_{Q,P} \), is responsible for the loss of classical covariance in the quantum case. One exceptional case in which \( \ast_q = \ast_{Q,P} \) can be identified corresponds to the group of linear canonical transformations, i.e. \( Sp_2(\mathbb{R}) \) as given by

\[ \begin{pmatrix} p \\ q \end{pmatrix} = g \begin{pmatrix} p \\ q \end{pmatrix}, \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in Sp_2(\mathbb{R}) . \]  
(43)

By conjugation,

\[ \left( \frac{\partial_p}{\partial_q} \right) = (g^T)^{-1} \left( \frac{\partial_p}{\partial_q} \right), \quad (g^T)^{-1} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} . \]  
(44)

By direct inspection of Eq. (14), and (11), the invariance of the \( \ast \) product, i.e. \( \ast_q = \ast_{Q,P} \), is guaranteed by the constant coefficients. We now demonstrate, for the linear canonical transformations, the manifestation of the classical covariance in Eq. (11) and for a more general case \( f(p, q) = p^m q^n \). By using the associativity property of \( \ast_q \) we note that \( p^m q^n = [p^m] [q^n] \) where \( [x^k] = [\ast \ast \ast \cdots \ast] \) with \( \ast = \ast_q \). Since mixtures of the \( \ast \) and the ordinary product is not associative, one must perform them in the order which is denoted by the square brackets above. Namely, we first perform the calculations within each square bracket and then multiply them by using the ordinary multiplication. Denoting a generator of the linear canonical transformation \( \Omega \) by \( \hat{V}_Q \), we find that \( f' = P_m \ast_q \{ e^{i\gamma} \hat{V}_0 \} \ast^{-1} \{ e^{-i\gamma} \hat{V}_0 \} Q^n \) where we have \( \ast = \ast_{q,p} \). Since \( \ast_q = \ast_{Q,P} \) we have \( \ast \{ e^{i\gamma} \hat{V}_0 \} \ast^{-1} \{ e^{-i\gamma} \hat{V}_0 \} = 1 \). Here \( \ast^{-1} \) is defined as the inverse of the star product which is well defined and corresponds to the complex conjugate of \( \ast \). We therefore have \( f' = [P_m] [Q^n] = P_m Q^n \) for all nonnegative \( m, n \). Hence, under linear canonical transformations we have the desired covariance

\[ [e^{i\gamma} \hat{V}_n f](z) = f(Z) \]  
(45)
and all other classical properties in Eq’s (10-9) can be easily derived for the linear canonical transformations here.

Note that, the three quantum generators of the linear canonical algebra $sp_2(\mathbb{R})$ are given by

$$A_1 = -\frac{1}{4}(\hat{p}^2 - \hat{q}^2), \quad \hat{V}_{A_1} = \frac{i\hbar}{2}(p\partial_q + q\partial_p)$$

$$A_2 = \frac{1}{4}(\hat{p}^2 + \hat{q}^2), \quad \hat{V}_{A_2} = -\frac{i\hbar}{2}(p\partial_q - q\partial_p)$$

$$A_3 = \frac{1}{4}(\hat{p}\hat{q} + \hat{q}\hat{p}), \quad \hat{V}_{A_3} = \frac{i\hbar}{2}(p\partial_p - q\partial_q).$$

The corresponding classical generators $L_{G_k}$ are generated by the same quadratic polynomials $A_k$ in (46). It is observed that the quantum generators are identical to the classical generators (up to an $i\hbar$ factor), i.e. $\hat{V}_{A_k} = i\hbar L_{G_k}$. In ref. [4] three types of quantum phase space generators, i.e. the generators of $sp_2(\mathbb{R})$, the gauge and the contact transformations, have been studied. For all three cases exact solutions are possible and the quantum generating functions are identical to the classical ones. These three generators therefore generate the same canonical algebra and the group of transformations in the classical and quantum phase spaces. No other class of transformations have been found yet having this universal property between the classical and quantum cases. In the light of these possibilities, it was suggested that the canonical algebra is spanned solely by these three classes of generators which is an important issue yet to be settled.

The time evolution as a canonical transformation, can also be represented in terms of the MLT. Like in the classical case, the Hamiltonian function is the generator of time translations in the phase space. This will be examined in section 4. We now examine the question of associativity in the classical and the quantum phase space algebras.

C. Associativity and classical phase space

The Poisson bracket as an algebraic extension of the abstract Lie bracket is not associative. One way to understand this is to construct a Poisson product $\times$ which can be defined as

$$\times = \frac{1}{2} \frac{\partial}{\partial z} J \frac{\partial}{\partial z}$$

so that the Poisson bracket is represented as

$$\{g, f\}^{(P)} = g \times f - f \times g.$$ 

The $\times$-product satisfies the left and right distributive and the scalar laws. Hence it is a linear algebra. Nevertheless it is non associative, i.e. $g \times (f \times h) \neq (g \times f) \times h$ which can be checked quite easily.

Why is associativity so important in classical phase space? In pre quantum mechanical times the answer to this question would be in order to understand the classical phase space as a group manifold on which a theory of Lie transformations can be established. A number of attempts in this direction have been made in the past but the most serious considerations started after the advent of quantum mechanics and were inspired by it.
From the classical point of view, the quantum mechanical $\star$-product can be realized as an associative non-commutative and $\hbar$ parameterized deformation of the $\times$-product in Eq. (47).

We may write the $\star$ product in terms of the Poisson product as,

$$\star = \exp\{i\hbar \times\}.$$  (49)

The associativity of the $\star$-product is clear by its analytic correspondence with the Lie bracket. It can be illustrative to demonstrate how associativity is manifested in the phase space directly. Using Eq. (25) we note that, the left and right multiplication in $\star$-product defined by Eq. (17) commute as

$$[f \star g]_\star = f(\hat{z}_R) g(\hat{z}_L) - g(\hat{z}_L) f(\hat{z}_R) = 0$$  (50)

for any two functions $f$ and $g$. Now consider three such functions $f, g, h$ as

$$[f \star h]_\star g = g(\hat{z}_L) f(\hat{z}_R) h = f(\hat{z}_R) g(\hat{z}_L) h$$  (51)

where we used (50) in the last step in (51). The last equality implies that the differential operator $f(\hat{z}_R)$ acts on all functions on its right

$$f(\hat{z}_R) g(\hat{z}_L) h = f(\hat{z}_R) [g(\hat{z}_L) h] = f(\hat{z}_R) [h \star g] = [h \star f]_\star g$$  (52)

Associativity of the $\star$-product is then proved by a comparison of Eq’s (51) and (52). However in the case of Poisson product the classical version of (50) is given by $[f \times, g] \neq 0$ for arbitrary $f, g$ causing Eq’s (51) and (52) to be invalid.

The associativity of the $\star$-product, combined with its manifest covariance under unitary transformations described by Eq. (35) demonstrates that the $\star$-product is the algebraic partner in the quantum phase space of the ordinary functional product in the classical phase space. The coexistence of the $\star$ and ordinary products such as in (10) is very commonly encountered when the unitary transformation of a function $f(z)$ is to be calculated. It was proved in Eq’s (13) that, with the exception of $sp_2(\mathbb{R})$ an arbitrary transformation does not preserve the classical covariance property. Here, we have an example of that from time evolution.

**D. $\star$-covariant time evolution in the phase space**

In the standard formulations of the quantum mechanics the transformations can be represented by their actions on the states or on the operators or some consistent mixture of both. For the specific case of the time evolution these are known as the Schrödinger, Heisenberg and interaction pictures respectively. We argue in the following in favor of adding to this gallery the phase space picture. One distinction of the phase space picture with respect to the other pictures is that it is essentially an operator picture. In this operator picture the quantum states in the Hilbert space that the phase space operators act on are represented by the density operator. The second distinction is that every admissible phase space operator (see section 2.1) is uniquely mapped onto an admissible phase space function and the operator product is uniquely mapped onto the $\star$-product. In this scheme, the density operator is uniquely mapped to a Wigner function. In the positivist point of view, the second
present in the Hamiltonian and/or in oscillator high orders can, in principle, be performed numerically for the binomials computations imported by the new rule of functional multiplication, i.e. is also possible. A negativist view can be based upon concentrating on the difficulties in the nonlinear polynomials in increasing power of the phase space trajectories generated by Eq. (56). The series expansion generates highly distanced greatly facilitates the use of the conceptual tools to see the quantum dynamics as a classical dynamics on a deformed phase space. On the other hand, the opposite view is also possible. A negativist view can be based upon concentrating on the difficulties in the computations imported by the new rule of functional multiplication, i.e. the classical and quantum cases significantly differ. A typical example is the time evolution.

The time evolution in the phase space is a clear picture allowing a comparative analysis of the classical and quantum dynamics given by the same Hamiltonian \( H_t(z) \). In the quantum case we assume that \( H_t(z) \) can be mapped to a quantum mechanical Hamiltonian operator \( \hat{H}_t \) through the Weyl correspondence, i.e. \( H_t(z) \leftrightarrow \hat{H}_t \). An arbitrary function \( f \) of the dynamical variables \( z \) will be denoted by \( f^{(c)}_t(z) \) and \( f^{(q)}_t(z) \) as the classical and quantum solutions corresponding to \( f \). To facilitate the comparison further, we also assume that at a certain initial time \( t_0 = 0 \), \( f^{(c)}_0(z) = f^{(q)}_0(z) = f_0(z) \). The classical time evolution can be calculated as

\[
f^{(c)}_t(z) = \mathcal{T} e^{\int_0^t dt' L_{H_t'}} f^{(c)}_0(z) .
\]

where \( \mathcal{T} \) is the time ordering operator defined in the standard way by

\[
\mathcal{T} e^{\int_0^t dt' L_{H_t'}} = 1 + \epsilon \int_0^t dt' L_{H_t'} + \frac{1}{2!} \epsilon^2 \int_0^t dt' L_{H_t'} \int_0^{t'} dt'' L_{H_{t''}} \ldots
\]

If Eq. (20) is considered for the quantum time evolution generated by \( \hat{U}_{H_t} \), then by Eq’s (26)-(29), the finite time evolution is represented in the phase space by

\[
f^{(q)}_t(z) = \mathcal{T} e^{-\frac{i}{\hbar} \int_0^t dt' \hat{V}_{H_t'}} f_0(z) , \quad \hat{V}_{H_t'} = H_{t'} \star - \star H_{t'} .
\]

For Hamiltonians quadratic in \( z \) Eq’s (53) and (55) yield identical results. For such quadratic Hamiltonians \( L_{H_t} = i\hbar \hat{V}_H \) and hence the time evolution is covariant, i.e. \( f_t(z) = f_0(\mathcal{T} e^{-\frac{i}{\hbar} \int_0^t dt' \hat{V}_{H_t'}} z) \). The difference arises when the third and higher order terms in \( z \) are present in the Hamiltonian and/or in \( f_0 \). For example consider the typical case of the quartic oscillator \( H = H_0 + \frac{\lambda}{4} q^4 \) where \( H_0 = (p^2 + q^2)/2 \). Using (55) we have

\[
\hat{V}_H = -i\hbar (p \partial_q - q \partial_p) + i\hbar \lambda \left[ q^3 \partial_p - \left( \frac{\hbar}{2} \right)^2 q \partial_p \right]
\]

There is no known method of calculating the exact analytic forms of the time dependence of the phase space trajectories generated by Eq. (56). The series expansion generates highly nonlinear polynomials in increasing power of \( z \) at each order. A finite series of arbitrarily high orders can, in principle, be performed numerically for the binomials \( p^m q^n \). Exact results can be achieved for the type of Hamiltonians \( H = p^2/2 + V(q) \) if a periodic kick is introduced in the interaction \( V(q) \). The model we consider is the periodically kicked Hamiltonian

\[
H(z) = \frac{p^2}{2} + \lambda V(q) \delta_T(t)
\]

where \( \delta_T(t) \) is the periodic delta-kick function with the period \( T \). The quantum case for (57) is exactly solvable for arbitrary potentials \( V(q) \) and the solution is identical to the classical
case. We start with the classical one. The transformation induced by Eq. (57) in one full step is given in terms of a time ordered product of two unitary Lie generators as

\[
f_{n+1}^{(-)}(z) = e^{T L_{V}/2} e^{\lambda L_{V}} f_n^{(-)}(z) \\
= f(e^{T L_{V}/2} e^{\lambda L_{V}} z) = f(z_n^{(-)})
\]  

(58)

where the classical covariance condition is explicitly stated in the second part of the equation. The minus sign in the superscript indicates that the value of \( f_n \) is calculated infinitesimally before the \( n \)’th kick. The time dependence for \( z_n \) is given by the standard result

\[
\tilde{p}_{n+1}^{(-)} = \tilde{p}_n^{(-)} + \kappa \mathcal{V}(q_{n+1}) , \quad q_{n+1} = q_n - \tilde{p}_n^{(-)},
\]

(59)

with \( \tilde{p}_n = T p_n \) and \( \kappa = T \lambda \).

The quantum analog of Eq. (58) in the operator space is the time ordered quantum evolution operator

\[
\hat{U}_H = e^{-\frac{i}{\hbar} \hat{p}^2/2} e^{-\frac{i}{\hbar} \lambda \mathcal{V}(\hat{q})},
\]

(60)

where \( \mathcal{V}(\hat{q}) \) is the operator corresponding to the potential \( \mathcal{V}(q) \). The unitary Lie generators are determined by Eq. (53). Time ordering brings complications and therefore we explicitly derive \( \hat{V}_H \) from Eq. (20) and Eq. (29). Consider Eq. (30) and section 2.2 that such transformations create an equivalence class maintaining the covariance under time evolution. The analogy with the classical trajectories is limited to Eq’s (59) and (63) or to those obtained from Eq’s (59) and (63) by linear canonical transformations. It was discussed in section 2.2 that such transformations create an equivalence class maintaining the covariance under time evolution.

It is expected that the time evolution is non-covariant for a general function of phase space. By direct inspection it is observed that polynomials \( P_r(z) \) of degree \( r \leq 2 \) evolve identically
in the classical and quantum cases. As a specific example we calculate the one time step quantum evolution of \( f = p^3 q \) which is of order \( r = 4 \) in \( z \). We find \( \mathcal{O}(\hbar^2) \) difference between the non-covariant full quantum solution and the covariant classical part indicated by \((q)\) and \((c\ell)\) respectively. The difference is

\[
[p^3 q]_{n+1}^{(q)} - [p^3 q]_{n+1}^{(c\ell)} = [p^3 q]_{n+1}^{(q)} - p_{n+1}^3 q_{n+1} = -\frac{3}{2} \lambda \hbar^2 \partial_q^3 V(q) \bigg|_{q=q_{n+1}}
\]

where use have been made of \([p^3 q]_{n+1}^{(c\ell)} = (p_{n+1})^3 q_{n+1} \) where the latter are, i.e. \( p_{n+1}, q_{n+1} \) the same for the classical and the quantum cases. It turns out that a generic difference between the \((q)\) and \((c\ell)\) transformations of any function is always \( \mathcal{O}(\hbar^2) \) or higher. One immediate observation in Eq. (64) is that it is no longer possible, even after suitable normalizations, to express \([p^3 q]_{n+1}^{(q)}\) by the parameter \( \kappa \). The reason is the broken classical covariance under the time evolution. The second observation in Eq. (64) is that, depending on the shape of the potential \( V(q) \), the long time behavior of the classical and quantum solutions can be very different. If the third derivative of the potential is oscillatory, like in the standard map, the difference between the long time averages of the classical and quantum solutions in Eq. (64) vanishes. For polynomial potentials the right hand side in Eq. (64) is unbounded. In this case, and for sufficiently large \( n \), the classical and the quantum solutions can differ significantly.

Another feature of non covariance is about the time evolution of dynamical systems that are related to each other by nonlinear canonical transformations. Such transformations may help in understanding fundamentally different quantum behavior of the classically equivalent systems. As a typical case under the evolution by the Hamiltonian in (57) consider the gauge transformation

\[
q \mapsto Q = q + a p^3, \quad p \mapsto P = p
\]

where \( a \) is a real parameter. Because of the nonlinear momentum dependence the quantum evolution of the new pair described by \( P_n, Q_n \) differs from its classical partner. For (65) only the transformation of \( Q \) is nontrivial. It can be calculated as

\[
Q_{n+1}^{(q)} - Q_{n+1}^{(c\ell)} = a \left( [p^3 q]_{n+1}^{(q)} - [p^3 q]_{n+1}^{(c\ell)} \right) = a \left( [p^3 q]_{n+1}^{(q)} - p_{n+1}^3 \right) = -\hbar^2 a \lambda \frac{3}{4} \partial_q^3 V(q) \bigg|_{q=q_{n+1}}.
\]

What (66) says is that not only the classical and the quantum solutions, but also the transformed and untransformed quantum solutions differ under Eq. (53).

### E. Equivalence to the \( \star \)-exponential formalism

The quantum Lie generator formalism as outlined in section 2.2 can become an indispensable tool in the quantum phase space. The equivalence of the Lie generators to the quantization by the \( \star \)-exponential can be easily demonstrated.

Consider the unitary transformation \( \hat{U}_A = e^{i V_A} \). Expanding \( \hat{U}_A \) in power series of \( \hat{A} \) and applying the Weyl map \( \hat{A}^r \iff \underbrace{\hat{A} \star \cdots \star \hat{A}}_{r} \) we find that
\( \hat{U} \iff \ U = e^{i\gamma A} = 1 + i\gamma A + \frac{(i\gamma)^2}{2!} A \star A + \frac{(i\gamma)^3}{3!} A \star A \star A + \ldots \) \hspace{1cm} (67)

Eq. (67) is the well known \( \star \)-exponential. The \( \star \)-exponential can be used in the transformation of \( f \) as

\[
f'(z) = u^{(-1)} \star f \star u = e^{-i\gamma A} \star f(z) \star e^{i\gamma A}, \quad \star = \star_z \equiv \star_{q,p}
\]

(68)

This equation involves the \( \star \)-product of the \( \star \)-exponential and it’s direct calculation is notoriously difficult in yielding analytically closed forms. It is already difficult to calculate the \( \star \)-exponential and it is proven so at the most basic level, the harmonic oscillator. Using the MLT approach the harmonic oscillator solution can be derived quite effortlessly. The calculation can be found in Ref. [4]. By using (67) and the results in section C.2 \( e^{i\gamma A \star} \) in (68) can be expressed as

\[
e^{i\gamma A \star} = e^{-i\gamma (A \star)} = e^{-i\gamma (\hat{z}_R)}
\]

\[
\star e^{i\gamma A} = e^{i\gamma (\star A)} = e^{i\gamma (\hat{z}_L)}
\]

(69)

If we further use Eq. (25) we observe that Eq. (69) is equivalent to \( f' = e^{i\gamma \hat{V}_A} f \) as given by (30).

**F. Conclusion**

In this paper, we have introduced a new phase space approach to Weyl quantization referred to as the Moyal-Lie theory. MLT is basically a corrected Poisson-Lie theory by the manifestation of associativity by the \( \star \) product. The new approach is equipped with all other features of classical Hamiltonian vector fields. An exceptional case is the need for a new concept of covariance. It is shown here that the covariance is equipped in the non commutative phase space with a star product. This suggest that one may still be able to define trajectories in the non commutative (quantum) sense.

The new theory is formally equivalent to the \( \star \)-quantization of Flato et al. and Bayen et al. and it may be more appealing from the physical point of view. This is partially due to its aspect which has to do with the algebraic similarities with the classical Hamiltonian vector fields and the phase space Lie transformations. The second aspect is the connection with the theory of quantum canonical transformations in the phase space which is reported elsewhere.
