Abstract

This short paper should serve as basis for further analysis of a previously found new symmetry of the solutions of the wave equation in the gravitational field of a Kerr black hole. Its main new result is the proof of essential self-adjointness of the spatial part of a reduced normalized wave operator of the Kerr metric in a weighted $L^2$-space. As a consequence, it leads to a purely operator theoretic proof of the well-posedness of the initial value problem of the reduced Klein-Gordon equation in that field in that $L^2$-space and in this way generalizes a corresponding result of Kay (1985) in the case of the Schwarzschild black hole. It is believed that the employed methods are applicable to other separable wave equations.

1 General Introduction

The linearized stability of the Schwarzschild black hole follows by combination of the Regge-Wheeler-Zerilli-Moncrief decomposition of gravitational perturbations of the Schwarzschild metric \[15,18,12\] and a result by Kay and Wald \[11\] that proves the boundedness of all solutions of the wave equation corresponding to $C^\infty$-data of compact support. The proof of the last rests on the positivity of the conserved energy.

The question of the linearized stability of the Kerr black hole is still an open problem whose outcome is of major importance to General Relativity. In comparison to the case of the Schwarzschild black hole, the solution to this problem is considerably more complicated. Mainly, this is due to two facts. First, a decomposition comparable to that of Regge-Wheeler-Zerilli-Moncrief does not yet exist in this case, although the recent
finding of [5] gives hope that such a decomposition might exist. In contrast, a partial decomposition based on the Newman-Penrose formalism depends on the choice of a tetrad field, i.e., is gauge dependent even under ‘small’ coordinate transformations [1]. Second, a conserved energy for the solutions of the wave equation exists, but the energy density is negative inside the ergosphere. This fact excludes, at least a direct, application of the so-called ‘energy methods’ to a proof of stability of the solutions. The total energy could be finite while the field still may grow exponentially in parts of the spacetime. But recently a local stability result has been proved that the restrictions of the solutions to compact subsets \( K \) in space are elements of \( L^{\infty}_C(K) \) with a norm converging to zero for \( t \to \infty \) [8]. Because of the absence of a decomposition of the Regge-Wheeler-Zerilli-Moncrief type, the question of applicability of the last and similar other results to the question of linearized stability of the Kerr metric is still open.

As mentioned above, [5] contains the surprising find of a new symmetry operator that commutes with a normalized form of the wave operator in a Kerr background. Differently to previously known symmetry operators for the wave operator, this operator contains only a partial time derivative of the first order, but not of higher order. As a consequence, in formulations of the initial value problem for the wave equation in terms of first order systems of PDE and related formulations such as [3], this operator leads on an operator \( \hat{S} \) that formally commutes with the infinitesimal generator \( G \) of time evolution and therefore is a candidate for the generator of a strongly continuous semigroup or group of symmetries. In precise terms, \( \hat{S} \) should lead to an operator \( S \) that intertwines with the operators from the strongly continuous one-parameter group \( T : [0, \infty) \to L(Y,Y) \) generated by \( G \) [4], [9], i.e., which is such that

\[
ST(t) \supset T(t) S
\]

for all \( t \geq 0 \). Here \( Y \) denotes the space of data for the wave equation which is a complex Hilbert space [3]. The goal of the present note is to lay part of the foundation for a proof of the last in providing the new proof of the essential self-adjointness of the spatial part of the reduced normalized wave operator of the Kerr metric in a weighted \( L^2 \)-space. In addition, it is believed that the employed method in this might be applicable to other separable wave equations.

As a consequence, we also arrive at a purely operator theoretic proof of the well-posedness of the initial value problem of the reduced normalized Klein-Gordon equation in the gravitational field of a Kerr black hole in the weighted \( L^2 \)-space. The last space was already used in [3]. Also the last reference gives such a proof, but under the assumption that physical boundary conditions lead on the Friedrichs extension of the operator that is obtained from the spatial part of the reduced normalized wave operator of the Kerr metric by restriction to \( C^\infty \)-functions with compact support. In particular, the results in this note prove that this assumption is justified.

---

1In the following, the term ‘normalized’ means multiplication from the left by the factor \( 1/\rho^{00} \) in Boyer-Lindquist coordinates. For instance, such a ‘normalization’ takes place if the Klein-Gordon equation is solved for the second order time derivative of the unknown.

2i.e., on the level of tuples of functions that are differentiable to sufficiently high order.
2 The mathematical setting

In Boyer-Lindquist coordinates\(^3\), \((t,r,\theta,\phi) : \Omega \to \mathbb{R}^4\), the Kerr metric \(g\) is given by

\[
g = \left(1 - \frac{2Mr}{\Sigma}\right) dt \otimes dt + \frac{2Mar \sin^2 \theta}{\Sigma} (dt \otimes d\varphi + d\varphi \otimes dt) - \frac{\Delta}{\Sigma} dr \otimes dr - \Sigma d\theta \otimes d\theta - \frac{\Delta \Sigma}{\Sigma} \sin^2 \theta d\varphi \otimes d\varphi,
\]

where \(M\) is the mass, \(a \in [0, M]\) is the rotational parameter and

\[
\begin{align*}
\Delta &:= r^2 - 2Mr + a^2, \quad \Sigma := r^2 + a^2 \cos^2 \theta, \\
\Sigma &:= (r^2 + a^2) \Sigma + 2Ma^2 r \sin^2 \theta = \frac{(r^2 + a^2)^2}{\Delta} - a^2 \sin^2 \theta, \\
r_+ &:= M + \sqrt{M^2 - a^2}, \quad \Omega := \mathbb{R} \times (r_+, \infty) \times (-\pi, \pi) \times (0, \pi).
\end{align*}
\]

In these coordinates, the reduced wave equation, governing solutions of the form \(\psi(t,r,\theta,\phi) = \exp(i m \phi) u(t,r,\theta)\), where \(m\) runs through all integers, is given by

\[
\frac{\partial^2 u}{\partial t^2} + \frac{1}{\Sigma} \left( i \frac{4mMar}{\Delta} \frac{\partial u}{\partial t} - \frac{\partial}{\partial r} \Delta \frac{\partial u}{\partial r} - \frac{m^2 a^2}{\Delta} - \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta} + \frac{m^2}{\sin^2 \theta} \right) u = 0. \tag{1}
\]

The spatial part of the reduced normalized wave operator is given by

\[
D_{r\theta}^2 f := \frac{1}{\Sigma} \left( - \frac{\partial}{\partial r} \Delta \frac{\partial f}{\partial r} - \frac{m^2 a^2}{\Delta} - \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta} + \frac{m^2}{\sin^2 \theta} \right) f \tag{2}
\]

for every \(f \in C^2(\Omega, \mathbb{C})\). In particular, \(D_{r\theta}^2\) is singular since the continuous extensions of the coefficients of its highest (second) order radial derivative vanish on the horizon \(\{r_+\} \times [0, \pi]\). We represent the operator \(D_{r\theta}^2\) as the operator \(A\) below in the weighted \(L^2\)-space \(X\) defined by

\[
X := L^2_{\Sigma} \left( \Omega, g^{00} \sqrt{-|g|} \right).
\]

Here \(|g|\) denotes the determinant of the matrix \(g_{ab}\). Note that

\[
g^{00} \sqrt{-|g|} = \Sigma \sin \theta
\]

is singular at the horizon. Hence the elements of \(X\) vanish there in the mean. In the limit \(a \to 0\), this weight reduces to the one that is commonly used in the stability discussion of the Schwarzschild metric \cite{18, 10}.

\(^3\)If not otherwise indicated, the symbols \(t, r, \theta, \phi\) denote coordinate projections whose domains will be obvious from the context. In addition, we assume the composition of maps, which includes addition, multiplication and so forth, always to be maximally defined. For instance, the sum of two complex-valued maps is defined on the intersection of their domains. Finally, we use Planck units where the reduced Planck constant \(\hbar\), the speed of light in vacuum \(c\), and the gravitational constant \(\gamma\), all have the numerical value 1.
3 Properties of the spatial part of the reduced normalized wave operator

In the following, we prove that the operator $A_0$ defined below is linear, symmetric and essentially self-adjoint.\footnote{Note that the following operator $A_0$ corresponds to the operator $A_0 + C$ in [3].}

**Definition 1.**

(i) We define the domain of $A_0$ to consist of all $f \in C^2(\bar{\Omega}, \mathbb{C}) \cap X$ satisfying the conditions a), b) and c):

a) $D^2_{r\theta} f \in X$,

b) there is $R > 0$ such that $f(r, \theta) = 0$ for all $r > R$ and $\theta \in I_\theta := (0, \pi)$,

c) $\lim_{r \to r_+} \frac{\partial f}{\partial \theta}(r, \theta) = 0$

for all $\theta \in I_\theta$.

(ii) For every $f$ in the domain of $A_0$, we define

$$A_0 f := D^2_{r\theta} f.$$ 

**Lemma 2.** $A_0$ is a densely-defined, linear and symmetric operator in $X$. In addition, $A_0$ is semibounded from below with lower bound

$$\alpha := -\frac{m^2 a^2}{4M^2 r_+^2}.$$

**Proof.** In the following, $\langle \quad | \quad \rangle$ denotes the scalar product on $X$. Obviously, the domain of $A_0$ is a subspace of $X$ that contains $C^2_0(\Omega, \mathbb{C})$. Since the last is a dense subspace of $X$, that domain is a dense subspace of $X$. Further, $A_0$ is obviously linear. In particular, it follows for $f, g$ from the domain of $A_0$ that

$$\sum \sin \theta f^* A_0 g = \frac{\partial}{\partial r} \left\{ \Delta \sin \theta \left[ (\frac{\partial f}{\partial r})^* g - f^* \frac{\partial g}{\partial r} \right] \right\} + \frac{\partial}{\partial \theta} \left\{ \sin \theta \left[ (\frac{\partial f}{\partial \theta})^* g - f^* \frac{\partial g}{\partial \theta} \right] \right\}$$

and hence by Green’s theorem that

$$\langle f | A_0 g \rangle = \int_\Omega \sum \sin \theta f^* A_0 g \, dr d\theta = \int_\Omega \sum \sin \theta (A_0 f)^* g \, dr d\theta$$

$$= \langle A_0 f | g \rangle.$$ 

Hence, $A_0$ is symmetric. Further, it follows for $f$ from the domain of $A_0$ that

$$\sum \sin \theta f^*(A_0 - \alpha) f = -\frac{\partial}{\partial r} \left( \Delta \sin \theta f^* \frac{\partial f}{\partial r} \right) - \frac{\partial}{\partial \theta} \left( \sin \theta f^* \frac{\partial f}{\partial \theta} \right)$$

$$+ \sin \theta \left\{ \Delta \left| \frac{\partial f}{\partial r} \right|^2 + \left| \frac{\partial f}{\partial \theta} \right|^2 + \left( -\alpha \sum -\frac{m^2 a^2}{\Delta} + \frac{m^2}{\sin^2 \theta} \right) |f|^2 \right\}$$

$$\geq -\frac{\partial}{\partial r} \left( \Delta \sin \theta f^* \frac{\partial f}{\partial r} \right) - \frac{\partial}{\partial \theta} \left( \sin \theta f^* \frac{\partial f}{\partial \theta} \right),$$
where it has been used that
\[ \Sigma \geq \frac{4M^2r_+^2}{\Delta}. \]

Hence it follows by Green’s theorem that
\[ \langle f | (A_0 - \alpha) f \rangle = \int_\Omega \Sigma \sin \theta f^* (A_0 - \alpha) f \, drd\theta \geq 0 \]
and, finally, that \( A_0 \) is semibounded from below with lower bound \( \alpha \).

Remark 3. We note that the domain of \( A_0 \) contains all products \( f \otimes (P^m_l \circ \cos) \) where \( f \in C^2_0(I_r, \mathbb{C}) \) and \( P^m_l : (-1, 1) \to \mathbb{R} \) is the generalized Legendre polynomial corresponding to \( m \in \mathbb{Z} \) and \( l \in \{|m|, |m| + 1, \ldots \} \).

Theorem 4. \( A_0 \) is essentially self-adjoint.

Proof. According to a well-known criterion for essential self-adjointness\(^5\), it follows that \( A_0 \) is essentially self-adjoint if there is \( \lambda < -\alpha \) such that the range of \( A_0 - \lambda \) is dense in \( X \). The existence of such \( \lambda \) will be shown in the following. For this, we note that the elementary inequalities
\[ \frac{r^4}{\Delta} \leq \Sigma \leq \frac{4M^2}{r_+^2} \frac{r^4}{\Delta}, \tag{3} \]
imply that the underlying sets \( X \) of \( L^2_{C}(\Omega, r^4 \sin \theta/\Delta) \) are equal and that the corresponding norms that are induced on that set are equivalent. These facts are basic for the following.

In a first step, we note that the following holds for arbitrary \( \lambda \in \mathbb{C} \) and arbitrary \( f \) in the domain of \( A_0 \)
\[ (A_0 - \lambda)f = T_{r^4/(\Delta \Sigma)} \left[ \frac{1}{r^4/\Delta} \left( -\frac{\partial}{\partial r} \Delta \frac{\partial}{\partial r} - \frac{m^2a^2}{\Delta} \right) - \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta} + \frac{m^2}{\sin^2 \theta} \right] f \tag{4} \]
where \( T_{r^4/(\Delta \Sigma)}, T_{(\Delta \Sigma/r^4) - 1} \) denote the maximal multiplication operators in \( X \) with the functions \( r^4/(\Delta \Sigma) \) and \( (\Delta \Sigma/r^4) - 1 \), respectively. As a consequence of (3), \( T_{r^4/(\Delta \Sigma)} \) is defined on the whole of \( X \) as well as bounded and bijective. In addition, as a consequence of
\[ 0 \leq \frac{\Delta \Sigma}{r^4} - 1 \leq \frac{a^2}{M^2}, \]
it follows that \( T_{(\Delta \Sigma/r^4) - 1} \) is a bounded positive self-adjoint operator on \( X \). Motivated by (4), we define an auxiliary operator \( H \) in \( L^2_{C}(\Omega, r^4 \sin \theta/\Delta) \) whose domain \( D(H) \) coincides with the domain of \( A_0 \) and that is defined by
\[ Hf := \frac{1}{r^4/\Delta} \left( -\frac{\partial}{\partial r} \Delta \frac{\partial}{\partial r} - \frac{m^2a^2}{\Delta} \right) - \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta} + \frac{m^2}{\sin^2 \theta} \right) f. \]
for every \( f \in D(H) \). Utilizing \( H \), the identity (3) is equivalent to
\[ (A_0 - \lambda)f = T_{r^4/\Delta \Sigma} \left( H - \lambda - \lambda T_{(\Delta \Sigma/r^4) - 1} \right) f \tag{5} \]

\(^5\)E.g., see Section X.1 in [14].
for every $f \in D(H)$. Note that, differently to $A_0$, $H$ can be obtained by ‘separation’ from an operator which is in a certain sense ‘spherically symmetric’. This fact significantly simplifies the study of the properties of $H$.

In the next step, we show that $H$ is a densely-defined, linear, symmetric and essentially self-adjoint operator in $L^2_C(\Omega, r^4 \sin \theta/\Delta)$ which is semibounded from below with lower bound

$$\beta := - \frac{m^2 a^2}{r_+^2}.$$ 

In this, $\langle \cdot | \cdot \rangle$ denotes the scalar product of $L^2_C(\Omega, r^4 \sin \theta/\Delta)$. Indeed, it follows for $f, g \in D(H)$ that

$$r^4 \frac{\sin \theta}{\Delta} f^* H g = \frac{\partial}{\partial r} \left\{ \Delta \sin \theta \left[ \left( \frac{\partial f}{\partial r} \right)^* g - f^* \frac{\partial g}{\partial r} \right] \right\} + \frac{\partial}{\partial \theta} \left\{ \sin \theta \left[ \left( \frac{\partial f}{\partial \theta} \right)^* g - f^* \frac{\partial g}{\partial \theta} \right] \right\}$$

and hence by Green’s theorem that

$$\langle f | H g \rangle = \int_{\Omega} r^4 \frac{\sin \theta}{\Delta} f^* H g \, drd\theta = \int_{\Omega} r^4 \frac{\sin \theta}{\Delta} \langle H f | g \rangle \, drd\theta = \langle H f | g \rangle .$$

Hence, $H$ is symmetric. Further, it follows for $f \in D(H)$ that

$$r^4 \frac{\sin \theta}{\Delta} f^* (H - \beta) f = - \frac{\partial}{\partial r} \left( \Delta \sin \theta f^* \frac{\partial f}{\partial r} \right) - \frac{\partial}{\partial \theta} \left( \sin \theta f^* \frac{\partial f}{\partial \theta} \right)$$

and hence by Green’s theorem that

$$\langle f | (H - \beta) f \rangle = \int_{\Omega} r^4 \frac{\sin \theta}{\Delta} f^* (H - \beta) f \, drd\theta \geq 0$$

and, finally, that $H$ is semibounded from below with lower bound $\beta$. Hence it follows that $H$ is essentially self-adjoint if there is $\lambda < \beta$ such that the range of $H - \lambda$ is dense in $L^2_C(\Omega, r^4 \sin \theta/\Delta)$. This fact will be proved by application of the theory of Sturm-Liouville operators. For this, we define $I_r := (r_+, \infty)$,

$$X_r := L^2_C(I_r, r^4/\Delta)$$

and for every $l \in \{ |m|, |m| + 1, \ldots \}$ the Sturm-Liouville operators $A_{rml}, A_{rml0}$ in $X_r$ by

$$A_{rml0} f := - \frac{1}{r^4/\Delta} (\Delta f)'$$

$$A_{rml} f := \frac{1}{r^4/\Delta} \left\{ - (\Delta f)' + \left[ - \frac{m^2 a^2}{\Delta} + l(l+1) \right] f \right\}$$

$$= - \frac{1}{r^4/\Delta} (\Delta f)' + \frac{1}{r^4} \left[ l(l+1) \Delta - m^2 a^2 \right] f$$
for every \( f \in C^2_0(I_r, \mathbb{C}) \). Obviously, \( A_{rml0}, A_{rml} \) are both densely-defined, linear and symmetric. The equation \((\Delta f)' = 0\) has nonvanishing constants as solutions. Since these are not in \( X \), at both ends of \( I_r \), it follows that \( A_{rml0} \) is in the limit point case at \( r_+ \) and at \( + \infty \). Hence \( A_{rml0} \) is essentially self-adjoint (see, e.g., [17]). Further, since \([l(l + 1) \Delta - m^2 a^2]/r^4\) is bounded and real-valued, it follows from that by the Rellich-Kato theorem, e.g., see Theorem X.12 in Volume II of [14], that \( A_{rml} \) is also essentially self-adjoint and that the domains of the closures of \( A_{rml0} \) and \( A_{rml} \) and \( A_{rml} \), respectively, coincide. Obviously, \( \tilde{A}_{rml0} \) is semibounded from below with lower bound \( \beta \). Hence it follows that the range,
\[
\text{Ran}(A_{rml} - \lambda),
\]
of \( A_{rml} - \lambda \) is dense in \( X \), for \( \lambda < \beta \). In the following, we assume that \( \lambda < \beta \). We note that for every \( f \in C^2_0(I_r, \mathbb{C}) \) and \( l \in \{|m|, |m| + 1, \ldots\} \)
\[
(H - \lambda)[f \otimes (P^m_l \circ \cos)] = [(A_{rml} - \lambda)f] \otimes (P^m_l \circ \cos).
\]
Also, we denote the span of the elements of \( D(H) \) of the form
\[
f \otimes (P^m_l \circ \cos),
\]
where \( f \in C^2_0(I_r, \mathbb{C}) \) and \( l \in \{|m|, |m| + 1, \ldots\} \), by \( D \). That \((H - \lambda)D\), and hence also \( \text{Ran}(H - \lambda) \), is dense in \( L^2_\mathbb{C}(\Omega, r^4 \sin \theta/\Delta) \) can be concluded as follows. For this, let \( e_0, e_1, \ldots \) be some Hilbert basis of \( X_r \). Since \( P^m_{|m|} \circ \cos, P^m_{|m|+1} \circ \cos, \ldots \) is a Hilbert basis of \( L^2_\mathbb{C}(I_\theta, \sin) \), where \( I_\theta := (0, \pi) \), the family
\[
(e_k \otimes f_l)_{(k,l) \in \mathbb{N} \times \{|m|, |m| + 1, \ldots\}}
\]
is a Hilbert basis of \( L^2_\mathbb{C}(\Omega, r^4 \sin \theta/\Delta) \), where
\[
f_l := P^m_l \circ \cos
\]
for every \( l \in \{|m|, |m| + 1, \ldots\} \). Since \( \text{Ran}(A_{rml} - \lambda) \) is dense in \( X_r \), it follows by (6) that
\[
e_k \otimes f_l \in \text{Ran}(\lambda - \lambda D)
\]
for every \((k, l) \in \mathbb{N} \times \{|m|, |m| + 1, \ldots\} \). Since the span of the last family is dense in \( L^2_\mathbb{C}(\Omega, r^4 \sin \theta/\Delta) \), this implies that \((H - \lambda)D\) is dense in \( L^2_\mathbb{C}(\Omega, r^4 \sin \theta/\Delta) \). Hence \( H \) is also essentially self-adjoint.

In the final step, we use (5) to prove that
\[
\text{Ran}(A_0 - \lambda)
\]
is dense in \( X \). Since \( H - \lambda \) is essentially self-adjoint such that \( \bar{H} - \lambda \) is bijective and since
\[
-\lambda \bar{T}_{(\Delta \Sigma/r^4)}^{-1}
\]
is a positive bounded self-adjoint operator, it follows by the Rellich-Kato theorem that densely-defined, linear and symmetric operator
\[
H - \lambda - \lambda \bar{T}_{(\Delta \Sigma/r^4)}^{-1}
\]
is essentially self-adjoint and that the closure of this operator is bijective. Hence the range of this operator is dense in \( L^2_\mathbb{C}(\Omega, r^4 \sin \theta/\Delta) \) as well as in \( X \). Finally, since \( T_{r^4/(\Delta \Sigma)} \) defines a bijective bounded linear operator in \( X \), it follows by help of (5) that
\[
\text{Ran}(A_0 - \lambda)
\]
is dense in \( X \). Since \( \lambda < \beta \leq \alpha \), the last implies that \( A_0 \) is essentially self-adjoint. \( \square \)
4 The case of the Klein-Gordon equation

In the case of a Klein-Gordon field of mass \( \mu \geq 0 \), the equation corresponding to (1) is given by

\[
\frac{\partial^2 u}{\partial t^2} + \frac{1}{\Sigma} \left( i \frac{4mMar}{\Delta} \frac{\partial u}{\partial t} - \frac{\partial}{\partial r} \Delta \frac{\partial}{\partial r} - \frac{m^2a^2}{\Delta} - \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta} + \frac{m^2}{\sin^2 \theta} + \mu^2 \Sigma \right) u = 0.
\]

Hence in this case, the operator corresponding to \( A_0 \) is defined by

\[
A_{0\mu} := A_0 + T_h,
\]

where \( T_h \) denotes the maximal multiplication operator in \( X \) by the real-valued function \( h \) defined by

\[
h := \mu^2 \frac{\Sigma}{\Sigma}.
\]

Since the last is also bounded, \( T_h \) is a bounded self-adjoint operator on \( X \). Hence it follows by the Rellich-Kato theorem that \( A_{0\mu} \) is essentially self-adjoint if and only if \( A_0 \) is essentially self-adjoint. Since the last is the case, \( A_{0\mu} \) is essentially self-adjoint, too.

5 Consequences

As a consequence of the essential self-adjointness of \( A_{0\mu} \), the objects \( X, A_{\mu,-\alpha+\varepsilon} := A_{\mu} - \alpha + \varepsilon \), \( B \) and \( C : -(-\alpha + \varepsilon) \) are easily seen to satisfy Assumptions 1 and 4 of [2]. Here \( A_{\mu} \) denotes the closure of \( A_{\mu0} \) and \( \varepsilon > 0 \) is assumed to have the dimension \( l^{-2} \). The exact value of \( \varepsilon \) does not influence the results in any essential way. In addition, \( B \) denotes the maximal multiplication operator in \( X \) by the function multiplying \( i\partial u/\partial t \) in (7). Since that function is bounded and positive real-valued, \( B \) is a bounded linear and positive self-adjoint operator on \( X \) given by

\[
Bf = \frac{4mMar}{\Delta \Sigma} f
\]

for every \( f \in X \). Hence, application of the results of [2] give, in particular, the following well-posed formulation of the initial value problem for (7).

Theorem 5.

(i) By

\[
Y := D(A^{1/2}_{\mu,-\alpha+\varepsilon}) \times X
\]

and

\[
(\xi|\eta) := \langle A^{1/2}_{\mu,-\alpha+\varepsilon} \xi_1 | A^{1/2}_{\mu,-\alpha+\varepsilon} \eta_1 \rangle + \langle \xi_2 | \eta_2 \rangle
\]

for all \( \xi = (\xi_1, \xi_2), \eta = (\eta_1, \eta_2) \in Y \), there is defined a complex Hilbert space \( (Y, (\cdot|\cdot)) \).

(ii) The operators \( G \) and \( -G \) defined by

\[
G(\xi, \eta) := (-\eta, A_\mu \xi + iB\eta)
\]

for all \( \xi \in D(A_\mu) \) and \( \eta \in D(A^{1/2}_{\mu,-\alpha+\varepsilon}) \) are infinitesimal generators of strongly continuous semigroups \( T_+: [0, \infty) \to L(Y,Y) \) and \( T_-: [0, \infty) \to L(Y,Y) \), respectively.

\[6\]See also the Section 5.1 on 'Damped wave equations' in [4].
(iii) For every \( t_0 \in \mathbb{R} \) and every \( \xi \in D(A_\mu) \times D(A^{1/2}_{\mu,-\alpha+\varepsilon}) \), there is a uniquely determined differentiable map \( u : \mathbb{R} \to Y \) such that

\[
u(t_0) = \xi
\]

and

\[
u'(t) = -Gu(t)
\]

for all \( t \in \mathbb{R} \). Here ‘\( \cdot \)’ denotes differentiation of functions assuming values in \( Y \). Moreover, this \( \nu \) is given by

\[
u(t) := \begin{cases} T_+(t)\xi \quad &\text{for } t \geq 0 \\ T_-(t)\xi \quad &\text{for } t < 0 \end{cases}
\]

for all \( t \in \mathbb{R} \).
