Exact Moment Representation in Polynomial Optimization

Lorenzo Baldi, Bernard Mourrain
Inria d’Université Côte d’Azur, Sophia Antipolis, France

Abstract
We investigate the problem of representing moment sequences by measures in the context of Polynomial Optimization Problems, that consist in finding the infimum of a real polynomial on a real semialgebraic set defined by polynomial inequalities. We analyze the exactness of Moment Matrix (MoM) hierarchies, dual to the Sum of Squares (SoS) hierarchies, which are sequences of convex cones introduced by Lasserre to approximate measures and positive polynomials. We investigate in particular flat truncation properties, which allow testing effectively when MoM exactness holds and recovering the minimizers.

We show that the dual of the MoM hierarchy coincides with the SoS hierarchy extended with the real radical of the support of the defining quadratic module \(Q\). We deduce that flat truncation happens if and only if the support of the quadratic module associated with the minimizers is of dimension zero. We also bound the order of the hierarchy at which flat truncation holds.

As corollaries, we show that flat truncation and MoM exactness hold when regularity conditions, known as Boundary Hessian Conditions, hold (and thus that MoM exactness holds generically); and when the support of the quadratic module \(Q\) is zero-dimensional. Effective numerical computations illustrate these flat truncation properties.

1 Introduction
Let \(f, g_1, \ldots, g_s \in \mathbb{R}[X_1, \ldots, X_n]\) be polynomials in the indeterminates \(X_1, \ldots, X_n\) with real coefficients. The goal of Polynomial Optimization is to find:

\[
f^* := \inf \left\{ f(x) \in \mathbb{R} \mid x \in \mathbb{R}^n, \ g_i(x) \geq 0 \ for \ i = 1, \ldots, s \right\},
\]

that is the infimum \(f^*\) of the objective function \(f\) on the basic, closed semialgebraic set \(S := \{x \in \mathbb{R}^n \mid g_i(x) \geq 0 \ for \ i = 1, \ldots, s\}\). This is a general problem, which appears in many contexts and with many applications. To cite a few of them: in graph theory [LV22], network optimization design [MH15], control [HK14]; see [Las10] for a more comprehensive list. Equality constraints are also allowed in this setting, since \(g(x) = 0\) if and only if \(g(x) \geq 0\) and \(-g(x) \geq 0\). We can then consider optimization problems on real algebraic varieties, i.e. common zero loci of finitely many real polynomials. Moreover, many famous NP-hard and NP-complete problems can be rephrased as polynomial optimization problems, see e.g. [Lau09, Sec. 1.1].

To (approximately) solve such problems, Lasserre [Las01] proposed to use two hierarchies of finite dimensional convex cones depending on an order \(d \in \mathbb{N}\), and he proved, for Archimedean quadratic modules, the convergence of the optima associated to these hierarchies to the minimum \(f^*\) of \(f\) on \(S\), when \(d \to \infty\). The first hierarchy replaces non-negative polynomials by Sums of Squares (SoS) and non-negative polynomials on \(S\) by polynomials of degree \(\leq d\) in the truncated quadratic module \(Q_{2d}(g)\) generated by the tuple of polynomials \(g = \{g_1, \ldots, g_s\}\).

The second and dual hierarchy replaces positive measures by linear functionals \(L_{2d}(g)\) which are non-negative on the polynomials of the truncated quadratic module \(Q_{2d}(g)\). We will describe these constructions more precisely in section 2.1.

This approach has many interesting properties (see e.g. [Las15; Lau09; Mar08]). It was proposed with the aim to recover the infimum \(f^*\), and if this infimum is reached, the set of minimizers
The extraction of minimizers is strongly connected to the so called flat truncation property, that will be the focus of the paper.

To tackle these challenges, one can first address the finite convergence problem, that is when the value $f^*$ can be obtained at a given order of the relaxation(s). The second problem is the exactness of the hierarchies: we call the Sum of Squares (SoS) hierarchy exact when the non-negative polynomial $f - f^*$ belongs to the truncated quadratic module $Q_{2d}(g)$ for some $d \in \mathbb{N}$; and we call the Moment Matrix (MoM) hierarchy exact when, for all $d \in \mathbb{N}$ big enough, any optimal linear functional $\lambda^* \in L_{2d}(g)$ is represented by a positive measure supported on $S$. We are going to investigate in detail this exactness property of the MoM hierarchy.

Several works have been developed over the last decades to address SoS representation problems. [Par02] observed that if the complex variety $V_C(I)$ defined by an ideal $I = (h)$ generated by real polynomials is finite and $I$ is radical, then $f - f^*$ has a representation as a sum of squares modulo $I$. [Lau07] showed the finite convergence property if the complex variety $V_C(I)$ is finite, and that the truncated moment sequence at some level of the hierarchy has a representing measure, if moreover the ideal $I$ is radical. [Nie13c] showed that if the semialgebraic set $S$ is finite, then the finite convergence property holds for a preordering defining $S$.

[Sch05a] proved that $f - f^*$ is in the quadratic module $Q$ defining $S$ modulo the ideal $(f - f^*)^2$ if and only if $f - f^* \in Q$, and then the SoS hierarchy is exact. [Mar06], [Mar09] proved that, under regularity conditions at the minimizers, known as Boundary Hessian Conditions (BHC), $f - f^*$ is in the quadratic module, i.e., the SoS exactness property holds. [NDS06], [DNP07] showed that, by adding gradient constraints when $S = \mathbb{R}^n$ or KKT constraints when $S$ is a general basic semialgebraic set, the SoS exactness property holds when the corresponding Jacobian ideal is radical. [Nie13a] showed that, by adding the Jacobian constraints, the finite convergence property holds under some regularity assumption. [Nie13b] showed that finite convergence and the flat truncation property are equivalent under generic assumptions, if the SoS hierarchy is exact and strong duality holds. In [Nie14], it is shown that BHC imply finite convergence and that BHC are generic. [KS19] showed the SoS exactness property if the quadratic module defining $S$ is Archimedean and some strict concavity properties of $f$ at the finite minimizers are satisfied.

Though many works focused on the SoS hierarchy and the representation of positive polynomials with Sums of Squares, the MoM hierarchy has been much less studied. We mention [LLR08] and [Las+13], which prove that if $S$ is finite, the value $f^*$, the minimizers and the vanishing ideal of $S$ can be recovered from moment matrices associated with the truncated preordering defining $S$.

From a methodological and practical point of view, flat truncation tests on moment matrices, see e.g. [CF98] and [LM09], are a way to decide finite convergence, i.e. whether the minimum $f^*$ is reached at some order of the hierarchy (another approach is the comparison of the lower bound obtained with an objective value at a local minimizer). But flat truncation also implies MoM exactness. Moreover, it allows extracting the finite minimizers from moment matrices (see [HL05], [Mou18]), whereas SoS exactness does not yield the minimizers. Therefore a natural question, of theoretical and practical importance, is:

When does flat truncation hold in a Polynomial Optimization Problem?

It is known that truncated minimizing pseudo-moment sequences are not always represented by measures, see Appendix A and thus flat truncation does not hold in general. But surprisingly, no algebro-geometric characterization of when flat truncation holds has been described in the last decades.

Contributions. Our main contribution is a complete characterization of flat truncation in terms of the zero-dimensionality of a natural ideal defining the minimizers of the Polynomial Optimization Problem. Furthermore, we show that flat truncation for generic minimizing linear functionals implies the flat truncation property for all minimizing linear functionals, and the exactness property.

**Theorem A** (see Theorems 4.1 and 4.4). Assume that we have MoM finite convergence. Then \( \dim_{\mathbb{R}[X]} \text{supp}(\mathcal{C}(g + (f - f^*)) = 0 \) if and only if there exists $d$ such that a generic $\lambda^* \in L_{2d}^\text{fin}(f; g)$ has flat truncation.
In this case, all \( \lambda \in \mathcal{L}_{2d}^{\min}(f;g) \) have flat truncation, and the MoM hierarchy is exact.

Above, \( \text{supp}(Q(g)) := (Q(g) + (f - f^*)) \cap - (Q(g) + (f - f^*)) \) is an ideal, associated with the quadratic module \( Q(g) + (f - f^*) \) which defines the minimizers \( S_{2d}^{\min} \); \( \mathcal{L}_{2d}^{\min}(f;g) \) is the face of the minimizers of the MoM relaxation of order \( d \); and linear functionals in the relative interior of \( \mathcal{L}_{2d}^{\min}(f;g) \) are generic (see Definition 3.11 for a precise definition).

Theorem A easily allows to conclude that flat truncation occurs when regularity conditions, known as Boundary Hessian Conditions (BHC) hold true, see Definition 4.6. This conditions hold for generic \( g \) and \( f \).

**Theorem B** (see Theorem 4.7 and Corollary 4.8). Let \( f \in \mathbb{R}[X] \), \( Q = Q(g) \) be an Archimedean finitely generated quadratic module and assume that the BHC hold at every minimizer of \( f \) on \( S = S(g) \). Then the SoS hierarchy is exact, the MoM hierarchy is exact, and the flat truncation holds for all \( \lambda \in \mathcal{L}_{2d}^{\min}(f;g) \) when \( d \) is big enough. Moreover, this condition occurs for generic \( f \) and \( g \) satisfying the Archimedean condition.

Theorem B extends the results on finite convergence, SoS exactness and flat truncation proved in \([Mar06, Mar09, Nie13b, Nie14]\). A detailed comparison with these references is technical and therefore developed to Section 4.

Another consequence of Theorem 4.4, shown in Theorem 4.10, is that when the set \( S \) is finite, flat truncation holds if the quotient by the support of the quadratic module \( Q \) is of dimension zero. This generalizes results of \([LLR08, Las+13]\) on semidefinite moment representations on finite sets.

To prove these results, we investigate in detail the properties of truncated moment relaxations and their duals, i.e. properties of truncated quadratic modules \( Q_d(g) \) and positive linear functionals \( \mathcal{L}_d(g) \). These properties are summarized in Theorem C.

**Theorem C** (see Theorems 3.14, 3.18 and 3.19). If \( d \) is big enough, then the kernel of the (truncated) moment matrix of a generic \( \lambda^* \in \mathcal{L}_d(g) \) generates the real radical of \( \text{supp} Q(g) \). Furthermore, if \( \lambda^* \) has flat truncation, then \( \text{supp} Q(g) \) is zero-dimensional, \( S(g) \) is finite and the flat truncation degree is at least the interpolation degree of \( S(g) \).

Conversely, if \( \text{supp} Q(g) \) is zero-dimensional and \( d \) is big enough, then all \( \lambda \in \mathcal{L}_d(g) \) have the flat truncation property.

When the quotient by the support of \( Q \) is of dimension zero, Theorem C shows that (truncated) linear functionals in \( \mathcal{L}_d(g) \) are all represented by measures supported on \( S \), or in other words they are represented by convex combinations of evaluations at the points of \( S \). This is therefore a particular solution of the moment problem, in the spirit of Curto-Fialkow’s flat extension \([CF98]\).

A detailed comparison with related results in the zero-dimensional case, such as \([LLR08, Las+13]\), is performed in Section 3. The characterization of the ideal generated by the kernel of the moment matrix for generic linear functionals is new in the positive dimensional case.

**Outline.** The paper is structured as follows. In the next section of the introduction, we define the algebraic objects that we will use and recall their main properties. In Section 2 we describe in detail the notions of finite convergence and exactness for the Sum of Squares (SoS) and Moment Matrix (MoM) hierarchies. We present several examples showing how these notions are related (these examples are detailed in Appendix A).

In Section 3 we investigate the properties of truncated moment sequences (Section 3.1), of their annihilators (Section 3.2) and we analyze when flat truncation holds and relate it with the interpolation degree (Section 3.3).

In Section 4, we apply these results to Polynomial Optimization Problems (POPs). In Section 4.1 we prove necessary and sufficient conditions for flat truncation and analyze at which degree flat truncation holds and yields the minimizers. We prove that exactness and flat truncation hold for POPs satisfying the Boundary Hessian Conditions (Section 4.2), and under a zero-dimensionality assumption, which implies that the underlying semialgebraic set is finite (Section 4.3).
We say that \( I \) is dual to \( \mathcal{A} \). The space of linear functionals on \( \mathcal{A} \) is the vector space of polynomials of degree \( \leq t \).

Let \( \mathbb{R}[X] := \mathbb{R}[X_1, \ldots, X_n] \) be the \( \mathbb{R} \)-algebra of polynomials in \( n \) indeterminates \( X_1, \ldots, X_n \). We denote \( (h_1, \ldots, h_r) \subset \mathbb{R}[X] \) the ideal generated by \( h_1, \ldots, h_r \in \mathbb{R}[X] \).

We recall here basic notation and definitions we need hereafter, which can be found e.g. in textbooks [CL05; Las10; Mar08].

### 1.1 Notation

We denote \( \text{cone}(A) \) the convex cone generated by \( A \), by \( \text{conv}(A) \) its convex hull and by \( \langle A \rangle \) its linear span.

#### Polynomials

Let \( \mathbb{R}[X] := \mathbb{R}[X_1, \ldots, X_n] \) be the \( \mathbb{R} \)-algebra of polynomials in \( n \) indeterminates \( X_1, \ldots, X_n \). We denote \( (h_1, \ldots, h_r) \subset \mathbb{R}[X] \) the ideal generated by \( h_1, \ldots, h_r \in \mathbb{R}[X] \).

If \( A \subset \mathbb{R}[X] \) and \( t \in \mathbb{N} \), \( A_t := \{ f \in A \mid \deg f \leq t \} \). In particular \( \mathbb{R}[X]_t \) is the vector space of polynomials of degree \( \leq t \).

Given a finite set of polynomials \( g = \{ g_1, \ldots, g_r \} \), we define \( \Pi g := \{ \prod_{i \in J} g_i : \emptyset \neq J \subset \{1, \ldots, r\}\} = \{g_1, \ldots, g_r, g_1g_2, g_1g_3, \ldots, g_1 \cdots g_r\} \), the set of all the products of the \( g_i \)'s, and \( \pm g := \{g_1, -g_1, \ldots, g_r, -g_r\} \).

If \( A \subset \mathbb{R}[X] \) we define \( S(A) := \{ x \in \mathbb{R}^n \mid f(x) \geq 0 \forall f \in A \} \). In particular we denote \( S(g) = \{ x \in \mathbb{R}^n \mid g(x) \geq 0 \forall g \in g \} \) the basic, closed semialgebraic set defined by \( g \). If \( S \subset \mathbb{R}^n \), we denote \( \text{Pos}(S) = \{ f \in \mathbb{R}[X] : f(x) \geq 0 \forall x \in S \} \) the convex cone of nonnegative polynomials on \( S \).

Let \( \Sigma^2 = \Sigma^2[X] := \{ f \in \mathbb{R}[X] \mid \exists r \in \mathbb{N}, h_i \in \mathbb{R}[X] : f = h_1^2 + \cdots + h_r^2 \} \) be the convex cone of Sum of Squares polynomials (SoS), \( Q \subset \mathbb{R}[X] \) is called quadratic module if \( 1 \in Q \), \( \Sigma^2 \cdot Q \subset Q \) and \( Q + Q \subset Q \). If in addition \( Q \cdot Q \subset Q \), \( Q \) is a preorder. For a quadratic module \( Q \subset \mathbb{R}[X] \), we define \( \text{supp} Q := Q \cap -Q \). \( \text{supp} Q \) is an ideal of \( \mathbb{R}[X] \), see e.g. [Mar08, Prop. 2.1.2]. Given a finite set \( g = \{ g_1, \ldots, g_r \} \), we denote \( Q(g) \) the smallest quadratic module containing \( g \), i.e. \( Q(g) = \Sigma^2 + \Sigma^2 : g_1 + \cdots + \Sigma^2 : g_r \). Quadratic modules of the form \( Q(g) \) for finite \( g \subset \mathbb{R}[X] \) are called finitely generated. In a similar way, we denote \( T(g) = Q(\Pi g) \) the smallest preorder containing \( g \), also called finitely generated if \( g \) is finite.

We say that a quadratic module \( Q \) is Archimedean if \( 0 \leq r \in \mathbb{R} : r - \| Q \| \subset Q \). Notice that if \( Q \) is a finitely generated Archimedean quadratic module then \( \text{Supp}(Q) \) is compact, and these conditions are equivalent for finitely generated preorderings [Wor98, BW01]. We also recall that a finitely generated quadratic module \( Q \) is Archimedean if and only if there exists \( g \in Q \) such that \( S(g) \) is compact, see e.g. [Mar08, Th. 7.1.1].

For an ideal \( I \subset \mathbb{R}[X] \), the real radical of \( I \), denoted \( \sqrt{I} \), is the ideal:

\[
\sqrt{I} := \{ f \in \mathbb{R}[X] \mid \exists m \in \mathbb{N}, s \in \Sigma^2 \text{ with } f^{2m+s} \in I \}.
\]

We say that \( I \) is real or real radical if \( I = \sqrt{I} \).

Recall that \( \sqrt{I} = \text{supp} \text{supp}(I + \Sigma^2) \), see e.g. [Mar08, p. 23], and thus \( \sqrt{I} \) is a radical ideal. We are in particular interested in the case \( I = \text{supp} Q = Q \cap -Q \) for an arbitrary quadratic module \( Q \subset \mathbb{R}[X] \). In this case, the real radical and radical coincide: \( \sqrt{\text{supp} Q} = \sqrt{\text{supp} Q} \), see e.g. [Mar08, Note 2.1.4].

#### Linear functionals, truncations and moment matrices

For a \( \mathbb{R} \)-vector space \( V \), \( V^* \) is the dual space of linear functionals on \( V \). For \( \lambda \in V^* \), we denote \( (\lambda, v) = \lambda(v) \) the application of \( \lambda \) on \( v \in V \).

For \( A \subset V \), we define \( A_+ := \{ \lambda \in V^* \mid (\lambda, a) = 0 \forall a \in A \} \) and \( A_* := \{ \lambda \in V^* \mid (\lambda, a) \geq 0 \forall a \in A \} \).

Let \( (\mathbb{R}[X])^* \equiv \mathbb{R}[[Y]] := \mathbb{R}[[Y_1, \ldots, Y_n]] \), with the isomorphism given by \( (\mathbb{R}[X])^* \ni \lambda \mapsto \sum_{a \in \mathbb{N}^n} (\lambda, X^a) Y^a \in \mathbb{R}[[Y]] \), where \( Y^a \) is dual to \( [X]^a \), i.e. \( [Y]^a, [X]^a] = \delta_{a,b} \). When necessary, we will identify \( \lambda \in (\mathbb{R}[X])^* \) with its sequence of coefficients \( \lambda_a \) called pseudo-moments, in analogy to the case of a measure, where \( \lambda_a := (\lambda, X^a) \). See [Mou18] for more details on this approach, or [Las10, §3.2.1] for a classical presentation based on pseudo-moment sequences. Using linear functionals instead of pseudo-moment sequences allows us to treat dual elements, independently of any choice of basis in the primal space.

---

1[^1]: [https://github.com/AlgebraicGeometricModeling/MomentPolynomialOpt.jl](https://github.com/AlgebraicGeometricModeling/MomentPolynomialOpt.jl)
If \( t \leq s \in \mathbb{N} \) and \( \lambda \in (\mathbb{R}[X]_s)^* \) (or \( \lambda \in \mathbb{R}[X]_s^* \)), then \( \lambda^{[t]} \in (\mathbb{R}[X]_t)^* \) denotes its restriction to \( \mathbb{R}[X]_t \). Similarly if \( B \subset (\mathbb{R}[X]_t)^* \) then \( B^{[t]} := \{ \lambda^{[t]} \mid \lambda \in B \} \).

For \( t \leq r \in \mathbb{N} \), \( \lambda \in (\mathbb{R}[X]_r)^* \) and \( g \in \mathbb{R}[X]_r \), we define the convolution of \( g \) and \( \lambda \) as the element of \( (\mathbb{R}[X]_{r-t})^* \) defined by \( g \star \lambda : f \in \mathbb{R}[X]_{r-t} \mapsto \langle g \star \lambda, f \rangle = \langle \lambda, gf \rangle \). We denote \( \text{Ann}_t(\lambda) \) the annihilator of \( \lambda \) w.r.t. \( \star \) in degree \( \leq t \), that is \( \text{Ann}_t(\lambda) = \{ p \in \mathbb{R}[X]_t \mid p \star \lambda = 0 \} \). Given \( \lambda \in (\mathbb{R}[X]_r)^* \), \( r \geq 2t \), we define the Hankel operator:

\[
H_\lambda^t : (\mathbb{R}[X]_t) \to (\mathbb{R}[X]_t)^*
\]

\[
p \mapsto \langle p \star \lambda \rangle^{[t]}.
\]

The moment matrix of \( \lambda \) in degree \( t \) is the matrix \( H_\lambda^t = (\lambda_{\alpha,\beta})_{|\alpha| \leq t, |\beta| \leq t} \) of the Hankel operator \( H_\lambda^t \) with respect to the bases \( (X^\beta) \) and \( (Y^\alpha) \). Notice that the moment matrix \( H_\lambda^t \) can be also identified with the symmetric operator associated to the quadratic form \( p \in \mathbb{R}[X]_k \mapsto \langle \lambda, p^2 \rangle \). By definition, the kernel of the moment matrix \( H_\lambda^t \) is the annihilator of \( \lambda \) in degree \( \leq t \):

\[
\text{Ann}_t(\lambda) = \ker H_\lambda^t.
\]

If \( s \leq t \), we can identify the matrix of \( H_\lambda^t \) with the submatrix of \( H_\lambda^t \) indexed by monomials of degree \( \leq s \). The localizing matrix of \( \lambda \) at \( g \in \mathbb{R}[X] \) is the matrix \( H_{g^\star \lambda}^t = ((g \star \lambda)_{\alpha,\beta}) = (\Sigma_y g_y \lambda_{\alpha,\beta+y})_{\alpha,\beta} \) of the Hankel operator \( H_{g^\star \lambda}^t \). This coincides with the definition of localizing matrix used in the literature, see e.g. \([L10], \text{Eq. (3.14)}\).

## 2 Finite Convergence and Exactness

We describe now Lasserre SoS and MoM relaxations \([L10]\), and we define the exactness property. Hereafter we assume that the minimum \( f^* \) of the objective function \( f \) is always attained on \( S \), that is: \( S^{\min} := \{ x \in S \mid f(x) = f^* \} \neq \emptyset \).

### 2.1 Polynomial optimization relaxations

The construction of polynomial optimization relaxations relies on the approximation of the cone of positive polynomials by tractable convex cones, that we recall hereafter.

**Lasserre's SoS hierarchy.** For \( d \in \mathbb{N} \) let \( \Sigma^2_d \subset \mathbb{R}[X]_d \) be the finite dimensional convex cone of SoS of degree \( \leq d \). For \( d \in \mathbb{N} \) and \( g = \{ g_1, \ldots, g_r \} \subset \mathbb{R}[X] \), let

\[
Q_d(g) := \left\{ s_0 + \sum_{j=1}^r s_j g_j \in \mathbb{R}[X)_d \mid r \in \mathbb{N}, s_0 \in \Sigma^2_d, s_j \in \Sigma^2_{d - \deg g_j} \right\}
\]

be the truncated quadratic module generated by \( g \). For the applications in polynomial optimization, we are interested in quadratic modules truncated at even degrees.

We define the SoS relaxation of order \( d \) of problem \((1)\) as \( Q_d(g) \) and the supremum:

\[
f_{\text{SoS},d}^* := \sup \left\{ a \in \mathbb{R} \mid f - a \in Q_d(g) \right\}.
\]

### 2.2 Lasserre’s MoM hierarchy

To define the dual approximation of the polynomial optimization problem, we define for \( d \in \mathbb{N} \) and \( g = \{ g_1, \ldots, g_r \} \subset \mathbb{R}[X]_d \):

\[
L_d(g) := Q_d(g)^\vee = \{ \lambda \in (\mathbb{R}[X]_d)^* \mid \langle \lambda, q \rangle \geq 0 \ \forall q \in Q_d(g) \}
\]

the cone of positive linear functionals on \( Q_d(g) \), which is the dual convex cone to \( Q_d(g) \), see \([M08], \text{Sec. 3.6}\). By conic duality, \( Q_d(g) = L_d(g)^\vee \).

We have \( \lambda \in L_d(g) \) if and only if \( \langle \lambda, s \rangle \geq 0 \ \forall s \in \Sigma^2_d \) and \( \langle \lambda, sf \rangle \geq 0 \ \forall g \in g, \forall s \in \Sigma^2_d \) such that \( \deg gs \leq d \). Another equivalent way to describe \( L_d(g) \) is using positive semidefinite matrices or Linear Matrix Inequalities, since the \( L_d(g) \) are spectrahedra: \( \lambda \in L_d(g) \) if and only if the symmetric matrices \( H_{\lambda}^{[d-deg g]} \), \( H_{g_1^\star \lambda}^{[d-deg g]} \), \ldots, \( H_{g_r^\star \lambda}^{[d-deg g]} \) are positive semidefinite. As before, for the applications in
We easily verify that \( f \) (resp. \( f^* \)).

This will be the set of feasible pseudo-moment sequences of the MoM relaxation of order \( d \). With this notation we define the MoM relaxation of order \( d \) of problem (1) as:

\[
f_{\text{MoM},d}^* := \inf \{ \langle \lambda, f \rangle \in \mathbb{R} \mid \lambda \in \mathcal{L}^{(1)}_{2d}(g) \}.
\]

We easily verify that \( f_{\text{SoS},d}^* \leq f_{\text{MoM},d}^* \leq f^* \).

**Definition 2.1.** Consider the problem of minimizing \( f \in \mathbb{R}[X] \) on \( S(g) \). We define the set of minimizing linear functionals at relaxation order \( d \) as the linear functionals \( \lambda \) minimizing (3), i.e.

\[
\mathcal{L}^{\min}_{2d}(f; g) := \{ \lambda \in \mathcal{L}^{(1)}_{2d}(g) \mid \langle \lambda, f \rangle = f_{\text{MoM},d}^* \}.
\]

When \( Q(g) \) is Archimedean and \( d \) is big enough, the infimum \( f_{\text{MoM},d}^* \) is attained and \( \mathcal{L}^{\min}_{2d}(f; g) \) is nonempty, see [HH16] and [Bal22], p. 101. Geometrically, \( \mathcal{L}^{\min}_{2d}(f; g) \) is the exposed face of the minimizers of the MoM relaxation of order \( d \).

We now introduce two convergence properties that will be central in the article.

**Definition 2.2 (Finite Convergence).** We say that the SoS hierarchy \( (Q_{2d}(g))_{d \in \mathbb{N}} \) (resp. the MoM hierarchy \( (\mathcal{L}_{2d}(g))_{d \in \mathbb{N}} \)) has the Finite Convergence property for \( f \) if \( \exists d \in \mathbb{N} \) such that \( f_{\text{SoS},d}^* = f^* \) (resp. \( f_{\text{MoM},d}^* = f^* \)).

Notice that if the SoS hierarchy has finite convergence then the MoM hierarchy has finite convergence too, since \( f_{\text{SoS},d}^* \leq f_{\text{MoM},d}^* \leq f^* \). Moreover, if \( f_{\text{MoM},d}^* = f^* \) then \( \mathcal{L}^{\min}_{2d}(f; g) = \{ \lambda \in \mathcal{L}^{(1)}_{2d}(g) \mid \langle \lambda, f \rangle = f^* \} \).

**Definition 2.3 (SoS Exactness).** We say that the SoS hierarchy \( (Q_{2d}(g))_{d \in \mathbb{N}} \) is exact for \( f \) if it has the finite convergence property and \( \exists d \in \mathbb{N} \) such that \( f - f^* \in Q_{2d}(g) \) (in other words \( \sup = \max \) in the definition of \( f_{\text{SoS},d}^* \)).

Notice that, by definition, if the conditions for SoS and MoM finite convergence, and SoS exactness, hold true at order \( d \), then they hold true at order \( k \) for all \( k \geq d \).

For the moment hierarchy we can ask the property that every truncated functional minimizer is represented by a measure. This is the most natural condition which implies the finite convergence of the MoM hierarchy. We will show in Section 4 that flat truncation (the condition used in practice to verify the finite convergence and to extract the minimizers) implies that every truncated functional minimizer is represented by a measure.

In the following we denote \( \mathcal{M}(S) \) the finite positive Borel probability measure supported on \( S \), which are identified with the induced moment linear functionals \( f \mapsto \int f \, d\mu \) acting on polynomials. \( \mathcal{M}(S)^{[k]} \) denotes the restrictions of such linear functionals to polynomials of degree \( \leq k \).

**Definition 2.4 (MoM Exactness).** We say that the MoM hierarchy \( (\mathcal{L}_{2d}(g))_{d \in \mathbb{N}} \) is exact for \( f \) if:

* it has the finite convergence property, and
* for every \( k \in \mathbb{N} \), there exists \( d = d(k) \in \mathbb{N} \) such that every truncated functional minimizer is represented by a probability measure supported on \( S \), i.e. \( \mathcal{L}^{\min}_{2d}(f; g)^{[k]} \subset \mathcal{M}(S)^{[k]} \).

Notice that, in contrast with the previous definitions, in the definition of MoM exactness we require the property \( \mathcal{L}^{\min}_{2d(k)}(f; g)^{[k]} \subset \mathcal{M}(S)^{[k]} \) to hold for every \( k \), and in general the fact that the property is verified for particular \( k \) does not imply that it holds for every \( k \).

We show now an example where we investigate the properties of finite convergence and exactness.
Example 2.5. Consider the problem of minimizing \( f = X^2 \) on the semialgebraic set \( S = S(g) = S(1 - X^2 - Y^2, X + Y - 1) \subset \mathbb{R}^2 \) defined by \( g_1 = 1 - X^2 - Y^2 \) and \( g_2 = X + Y - 1 \). Clearly, the minimum is \( f^* = 0 \) and the only minimizer is \((0, 1)\). Notice that \( f - f^* = X^2 \in Q_2(1 - X^2 - Y^2, X + Y - 1) \) and therefore \( f_{\text{SoS}}^* = f_{\text{MoM}}^* = f^* = 0 \), we have finite convergence and the SoS hierarchy is exact.

We now investigate MoM exactness. If a truncated moment sequence \( \lambda \) is represented by a probability measure \( \mu \in \mathcal{M}^{(1)}(S) \) such that \( \int f\,d\mu = f^* \), then the support of \( \mu \) should be contained in the set of minimizers \( S_{\text{min}}^\mu = \{(0, 1)\} \) of \( f \). Thus \( \mu = e_{(0,1)} \) is the evaluation at \((0, 1)\) (or in other words, the Dirac measure concentrated at \((0, 1)\)). Its moments are easily computed: \( \mu_{00} = 1, \mu_{10} = 0, \mu_{01} = 1, \mu_{20} = 0, \mu_{11} = 0, \mu_{02} = 1 \).

Analyzing the constraints on the degree one and two moments of an optimal moment sequence \( \lambda \in L_2^{\text{min}}(f; g) \), where
\[
L_2^{\text{min}}(f; g) = \{ \lambda \in \mathbb{R}[X]_2 | H_1^0 \succeq 0, H_0^0 \succeq 0, H_0^0 \succeq 0, (\lambda, 1) = 1, (\lambda, f) = f^* = 0 \}
\]
we deduce that \( \lambda_{00} = 1, \lambda_{10} = 0, \lambda_{01} = 1, \lambda_{20} = 0, \lambda_{11} = 0 \) and \( \lambda_{02} = 1 \): this shows that the only element of \( L_2^{\text{min}}(f; g) \) is \( \lambda = e_{(0,1)}^{[2]} \). In particular notice that \( \langle \lambda, X^2 \rangle = (\lambda, Y - 1)^2 = 0 \).

For any order \( d \geq 1 \) and any element \( \lambda \in L_2^{\text{min}}(f; g) \), its truncation \( \lambda^{[2]} \) is in \( L_2^{\text{min}}(f; g) \) since \( \langle \lambda^{[2]}, X^2 \rangle = (\lambda, X^2) = 0 \). This implies that \( (\lambda, X^2) = (\lambda, Y - 1)^2 = 0 \) and thus \( \forall p \in \mathbb{R}[X], (\lambda, Xp) = (\lambda, (Y - 1)p) = 0 \), see e.g. [Las+13, Lem. 3.12]. We deduce from Proposition 3.15 that the moments of \( \lambda^{[d]} = e_{(0,1)}^{[d]} \) are represented by the Dirac measure \( e_{(0,1)}^{[d]} \). Therefore the MoM hierarchy is exact.

Another equivalent way to certify MoM exactness is to check flat truncation (see Definition 3.16).

We now investigate MoM exactness. If a truncated moment sequence \( \lambda \) is represented by a probability measure \( \mu \in \mathcal{M}^{(1)}(S) \) such that \( \int f\,d\mu = f^* \), then the support of \( \mu \) should be contained in the set of minimizers \( S_{\text{min}}^\mu = \{(0, 1)\} \) of \( f \). Thus \( \mu = e_{(0,1)} \) is the evaluation at \((0, 1)\) (or in other words, the Dirac measure concentrated at \((0, 1)\)). Its moments are easily computed: \( \mu_{00} = 1, \mu_{10} = 0, \mu_{01} = 1, \mu_{20} = 0, \mu_{11} = 0, \mu_{02} = 1 \).

Analyzing the constraints on the degree one and two moments of an optimal moment sequence \( \lambda \in L_2^{\text{min}}(f; g) \), where
\[
L_2^{\text{min}}(f; g) = \{ \lambda \in \mathbb{R}[X]_2 | H_1^0 \succeq 0, H_0^0 \succeq 0, H_0^0 \succeq 0, (\lambda, 1) = 1, (\lambda, f) = f^* = 0 \}
\]
we deduce that \( \lambda_{00} = 1, \lambda_{10} = 0, \lambda_{01} = 1, \lambda_{20} = 0, \lambda_{11} = 0 \) and \( \lambda_{02} = 1 \): this shows that the only element of \( L_2^{\text{min}}(f; g) \) is \( \lambda = e_{(0,1)}^{[2]} \). In particular notice that \( \langle \lambda, X^2 \rangle = (\lambda, (Y - 1)^2) = 0 \).

For any order \( d \geq 1 \) and any element \( \lambda \in L_2^{\text{min}}(f; g) \), its truncation \( \lambda^{[2]} \) is in \( L_2^{\text{min}}(f; g) \) since \( \langle \lambda^{[2]}, X^2 \rangle = (\lambda, X^2) = 0 \). This implies that \( (\lambda, X^2) = (\lambda, (Y - 1)^2) = 0 \) and thus \( \forall p \in \mathbb{R}[X], (\lambda, Xp) = (\lambda, (Y - 1)p) = 0 \), see e.g. [Las+13, Lem. 3.12]. We deduce from Proposition 3.15 that the moments of \( \lambda^{[d]} = e_{(0,1)}^{[d]} \) are represented by the Dirac measure \( e_{(0,1)}^{[d]} \). Therefore the MoM hierarchy is exact.

Another equivalent way to certify MoM exactness is to check flat truncation (see Definition 3.16).

For \( \lambda \in L_2^{\text{min}}(f; g) \) with \( d \geq 2 \), we have computed the moments of degree \( \leq 2 \). Since the moment matrices in degree \( \leq 2 \):
\[
H_1^0 = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad H_1^1 = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{pmatrix}
\]
have the same rank, the flat extension property is satisfied. This certifies that \( \lambda^{[2]} = e_{(0,1)}^{[2]} \) is represented by a measure supported at the minimizer of \( f \) on \( S \) and the MoM hierarchy is exact, see Theorem 4.1.

In practice, to check the finite convergence, one tests the flat extension or the flat truncation property (see [CF98, LM09, Nie13b]). But flat truncation certifies MoM exactness, and not only finite convergence. We will investigate flat truncation for POPs in Section 4, where it is also described in more detail its practical importance.

Notice that in the previous example the rank condition is satisfied by the full sequence of moments of \( \lambda \in L_2^{\text{min}}(f; g) \) (i.e. general this is not true, as the high degree moments may be increasing the rank of the moment matrix, see for in instance [Nie13b Ex. 1.1] and also [Qui21]). Therefore it is necessary to discard the high degree moments, i.e. to consider \( L_2^{\text{min}}(f; g)^{(t)} \), for some \( t \leq 2d \), instead of simply \( L_2^{\text{min}}(f; g) \). This implies that we look for rank conditions on the moment matrix of the truncated moment sequence (i.e. we use the flat truncation, see Definition 3.16). This point of view, of considering restrictions of linear functionals to a smaller degree, is a key concept in the manuscript, and it is ubiquitous in all our main results.

We finally recall that we are assuming \( S_{\text{min}} \neq \emptyset \) (and in particular \( f^* \) is finite). Notice also that if strong duality holds, then there is no duality gap and SoS finite convergence is equivalent to MoM finite convergence.

2.2 Examples and counterexamples

While for generic, regular polynomial optimization problems we expect both SoS exactness [Nie14]...
Table 1: Summary of convergence results.

| Expl. | SoS f. c. | SoS ex. | MoM f. c. | Flat tr. | MoM ex. | dim S |
|-------|-----------|---------|-----------|----------|---------|-------|
| A.1   | NO        | NO      | NO        | NO       | NO      | 0     |
| A.2   | NO        | NO      | NO        | NO       | NO      | 1     |
| A.3   | NO        | NO      | NO        | NO       | NO      | 2     |
| A.4   | NO        | YES     | NO        | NO       | NO      | ≥3    |
| A.5   | YES       | YES     | YES       | NO       | NO      | ≥3    |
| A.6   | YES       | YES     | YES       | NO       | NO      | 0     |
| A.7   | YES       | NO      | YES       | YES      | YES     | 0     |
| A.8   | YES       | NO      | YES       | YES      | YES     | 0     |

and MoM exactness with flat truncation (see Section 4.2 and [Nie13b]), these two notions are in general independent.

We collected and described in details known and new examples of these possible pathological behaviours in Appendix A. In particular, we produce new examples of optimization problems over finite semialgebraic sets, defined by Archimedean quadratic modules, where we do not have finite convergence and flat truncation, see Example A.1 and Example A.6. We summarize these examples in Table 1 in terms of the properties of finite convergence (SoS f. c. and MoM f. c.) exactness (SoS ex. and MoM ex.), flat truncation (Flat tr.) and the dimension of the semialgebraic set $S$.

3 Geometry of Moment Representations

Determining whether a linear functional on the polynomial ring is represented by a measure is the so-called Moment Problem. By Haviland’s theorem (see e.g. [Mar08, Th. 3.1.2] and [Sch17, Th. 1.12]) an infinite pseudo-moment sequence or a linear functional $\lambda \in \mathbb{R}[X]^*$ is represented by a measure, if and only if $\lambda$ is takes nonnegative values when applied to nonnegative polynomials. Since checking this is a computationally hard task, a motivation supporting Sum of Squares relaxations is to find (proper) subsets of positive polynomials that have the same property, but chosen in such a way that checking this condition is easy. An important result in this direction is the theorem of Putinar, refining the result of Schmüdgen.

**Theorem 3.1** ([Put93]). Let $Q(g)$ be an Archimedean quadratic module and $S = S(g)$. Let $\lambda \in \mathbb{R}[X]^*$. If $\langle \lambda, q \rangle \geq 0$ for all $q \in Q(g)$, then $\lambda \in M(S)$ is represented by a measure.

Hereafter we analyze in detail the properties of finite dimensional cones of truncated pseudo-moment sequences, and we investigate the truncated moment problem. Section 3.1 and Section 3.2 contains the main technical tools of the paper. We provide a new and explicit description of the dual of the hierarchy of truncated moment sequences, in terms of a quadratic module (Theorem 3.4), and consequently prove properties of the cones $L_d(g)$ (Lemma 3.6) and of their generic elements (Theorem 3.14). Finally we apply these results to the zero-dimensional case (Theorem 3.19) and we investigate the connections with the flat truncation property (Section 3.3).

3.1 Truncated moment representations

For a finitely generated quadratic module $Q = Q(g) \subset \mathbb{R}[X]$, we have $L_k(g) = Q_k(g)^\vee = \overline{Q_k(g)}^\vee$ and $L_k(g)^\vee = \overline{Q_k(g)}$, where $^\vee$ denotes the dual cone and the closure is taken w.r.t. the euclidean topology on $\mathbb{R}[X]_k$. Thus the following definition is natural for the study of the MoM relaxations.

**Definition 3.2.** Let $Q = Q(g)$ be a finitely generated quadratic module. We define $\overline{Q} = \bigcup_d \overline{Q_d(g)}$. 
Notice that \( \overline{Q} \) depends a priori on the generators \( g \) of \( Q \). We will prove that \( \overline{Q} \) is a finitely generated quadratic module and that it does not depend on the particular choice of generators. Moreover notice that \( Q \subset \overline{Q} = \bigcup_d Q_d(g) \subset \bigcup_d Q_d(g) = \overline{Q} \subset \mathbb{R}[X] \), where the closure in \( \mathbb{R}[X] \) is taken with respect to the finest locally convex topology, see e.g. [Mar08, Sec. 3.6]. We also remark that these inclusions can be strict, as we will discuss in this section (see in particular Example 3.5).

Recall that \( \text{supp} \ Q = Q \cap -Q \) is an ideal if \( Q \) is a quadratic module. Recall also that, if \( f \subset \mathbb{R}[X] \), then \( J_k = f \cap \mathbb{R}[X]_k \) denotes the intersection with the space of polynomials of degree \( \leq k \). In this section, we also denote \( \text{supp} Q_k(g) = \{ g \in \mathbb{R}[X] : \deg g \leq k \} \). We will prove that \( \overline{Q} = Q + J \) and \( \text{supp} \ Q = J \). In particular, \( \overline{Q} \) is a finitely generated quadratic module and does not depend on the particular choice of generators of \( Q \).

**Lemma 3.3.** Let \( Q = Q(g) \) and \( J = \sqrt{\text{supp} \ Q} \). Then for every \( d \in \mathbb{N} \) there exists \( k \geq d \) such that \( J_d \subset \overline{Q_k}(g) \).

**Proof.** We denote \( Q_{[d]} := Q_d(g) \). Let \( m \) be big enough such that \( \forall f \in J = \sqrt{\text{supp} \ Q} = \sqrt{\text{supp} \ Q} \) we have: \( f^{2m} \in \text{supp} Q \) (if \( \sqrt{\text{supp} \ Q} = \{ h_1, \ldots, h_t \} \) and \( h_i^a \in \text{supp} Q \), we can take \( m \) such that \( 2^m \geq a_1 + \cdots + a_t \)). Let \( f \in J_d \) with \( \deg f \leq d \). Then \( f^{2m} \in \text{supp} Q_{[k]} \subset Q_{[k]} \) for \( k \in \mathbb{N} \) big enough. Using the identity [Sch05b, Rem. 2.2]:

\[
\frac{m - a}{2} = (1 - \frac{a}{2})^2 + (1 - \frac{a^2}{3})^2 + \cdots + (1 - \frac{a^{2^{m-1}}}{2^{2^{m-1}-1}})^2 - \frac{a^{2^m}}{2^{2^m-1} - 2},
\]

substituting \( a = \frac{m - f}{\epsilon} \) and multiplying by \( \frac{1}{m} \), we have that \( \forall \epsilon > 0, f + \epsilon \in Q_{[k]} \) for \( k = \max[k', 2^md] \) (the degree of the representation of \( f + \epsilon \) does not depend on \( \epsilon \)). This implies that \( f \in \overline{Q_k} \).

We can now describe \( \overline{Q} = \bigcup_d \overline{Q_d}(g) \).

**Theorem 3.4.** Let \( Q = Q(g) \) be a finitely generated quadratic module and let \( J = \sqrt{\text{supp} \ Q} \). Then \( \overline{Q} = Q + J \) and \( \text{supp} \ Q = J \). In particular, \( \overline{Q} \) is a finitely generated quadratic module and does not depend on the particular choice of generators of \( Q \).

**Proof.** We denote \( Q_{[d]} := Q_d(g) \). By [Mar08, Lem. 4.1.4] \( Q_{[d]} + J_d \) is closed in \( \mathbb{R}[X]_d \), thus \( \overline{Q_{[d]}} \subset Q_{[d]} + J_d \). Taking unions we prove that \( Q \subset Q + J \).

Conversely by Lemma 3.3 for \( d \in \mathbb{N} \) and \( k \geq d \) \( J_d \subset \overline{Q_k} \). Then, we have \( Q_{[d]} + J_d \subset Q_{[k]} + J_d \subset Q_{[k]} \subset Q_{[k]} \subset Q_{[k]} \). Taking unions on both sides gives \( Q + J \subset Q \).

Finally \( \text{supp} \overline{Q} = \text{supp} (Q + J) = J \) by [Sch05b, Lem. 3.16].

**Remark.** We proved that \( \overline{Q} = Q + \sqrt{\text{supp} \ Q} \). We also have \( \text{supp} \overline{Q} = \sqrt{\text{supp} \ Q} \) so that if \( \text{supp} Q \) is not real radical then \( Q \subsetneq \overline{Q} \). Example A.8 is such a case where \( \text{supp} Q \neq \sqrt{\text{supp} Q} \). We notice that, by Theorem 3.4 and [Sch05b, Th. 3.17], if \( Q \) is stable then \( \overline{Q} = \overline{Q} \). But the inclusion \( \overline{Q} = Q + \sqrt{\text{supp} Q} \subset Q \) can be strict, as shown by the following example.

**Example 3.5** (Sch05a, Ex. 3.2], [Sch05b, Rem. 3.15], Example A.1, Example A.6). Let \( Q = \mathbb{Q}(1 - X^2 - Y^2, -X, Y, Y - X^2) \subset \mathbb{R}[X, Y] \). Notice that \( S = S(Q) = \{ 0 \} \) and that \( Q \) is Archimedean. Therefore, by Theorem 3.1 \( \overline{Q} = \text{Pos}(\{ 0 \}) \). One can verify that \( \text{supp} Q = \{ 0 \} \) and that \( \mathcal{I}(S) = \text{supp} \overline{Q} = (X, Y) \). Thus we have \( Q + \sqrt{\text{supp} Q} = \overline{Q} \subsetneq \overline{Q} \).

Theorem 3.4 suggests the idea that, when we consider the MoM hierarchy, we are extending the quadratic module \( Q(g) \) to \( Q(g, \pm h) \), where \( h \) are generators of \( \sqrt{\text{supp} Q(g)} \). We specify this idea in Lemma 3.10 Proposition 3.11 and Theorem 3.14 investigating the relations between the truncated parts of \( L_d(g) \). In the following, we denote \( \langle h \rangle_t = \{ \sum_i p_i h_i : p_i \in \mathbb{R}[X], \deg(p_i h_i) \leq t \} \) the vector space of polynomials in the ideal \( \langle h \rangle \) generated in degree \( \leq t \).

\( Q(g) \) is stable if \( \forall d \in \mathbb{N} \) there exists \( k \in \mathbb{N} \) such that \( Q(g) \cap \mathbb{R}[X]_d \subset Q_k(g) \cap \mathbb{R}[X]_d \).
Lemma 3.6. Let \( J = \sqrt[2]{\text{supp}} Q(g) \). If \( (h) \subset J, \deg h \leq t, \) then \( \exists d \geq t \) such that \( (h)_t \subset Q_d(g) \). In this case:

\[
L_d(g)[(t)] \subset L_t(g) \subset L_t(h).
\]

and in particular \( L_d(g)[(t)] \subset L_t(h) \). Moreover, \( L_{d+2k}(g)[(t+k)] \subset L_{t+k}(h) \) for all \( k \in \mathbb{N} \).

Proof. Let \( (h)_t \) be the vector space of polynomials in the ideal \( (h) \) generated in degree \( \leq t \). By Lemma 3.3, \( (h)_t \subset (h) \subset Q_d(g) \) for some \( d \geq t \). Let \( h \in h \) and \( f \in \mathbb{R}[X]_{t-deg h} \). Then \( \pm fh \in Q_d(g) \), and for \( \lambda \in L_d(g) \), we have \( \langle \lambda^{(t)}, fh \rangle = \langle \lambda, fh \rangle = 0 \), i.e. \( L_d(g)[(t)] \subset L_t(h) \). The other inclusion \( L_t(h) \subset L_t(g) \) follows by definition.

For the second part, notice that \( (h)_{t+k} \subset Q_{d+2k}(g) \). Indeed, if \( p \in (h)_{t+k} \) then \( p = \sum_i X^{a(i)} p_i \), where \( p_i \in (h)_t \subset Q_d(g) \) and \( |a(i)| \leq k \). Writing \( X^{a(i)} = (X^{a(i)+1})^2 - (X^{a(i)-1})^2 \), we deduce that \( p = \sum_i ((X^{a(i)+1})^2 - (X^{a(i)-1})^2) p_i \in Q_{d+2k}(g) \), i.e. \( (h)_{t+k} \subset Q_{d+2k}(g) \). Then we can conclude the proof as in the first part.

Remark. Lemma 3.6 says that the MoM hierarchy \((L_d(g)(n))_{n \in \mathbb{N}}\) is equivalent to the MoM hierarchy \((L_d(g)(n))_{d \in \mathbb{N}}\), where \( (h) = \sqrt[2]{\text{supp}} Q(g) \). Lemma 3.6 is an algebraic result, in the sense that \( \text{supp} Q(g) \) may be unrelated to the geometry \( S(g) \) that \( g \) defines. If some additional conditions hold (namely if we have only equalities, or a preordering, or a small dimension), it can however provide geometric characterizations. Recall that we denote \( \Pi g \) all the products of the \( g_i \)’s.

Corollary 3.7. Suppose that \( S(g) \subset \mathcal{V}_k(h) \). Then for every \( t_0 \geq \deg h \) there exists \( t_1 \geq t_0 \) such that:

\[
L_{t_1}(\Pi g)[t_0] \subset L_{t_1}(h).
\]

In particular this holds when \( (h) = I(S(g)) \).

Moreover, \( L_{t_1}(\Pi g)[t_0+k] \subset L_{t_1+k}(h) \) for all \( k \in \mathbb{N} \).

Proof. Recall the Real Nullstellensatz, see e.g. [Mar08] Note 2.22 (vi): \( I(S(g)) = \sqrt[2]{\text{supp}} T(g) \). Then \( S(g) \subset \mathcal{V}_k(h) \) if and only if \( \sqrt[2]{h} = \sqrt[2]{(\mathcal{V}_k(h))} \subset I(S(g)) = \sqrt[2]{\text{supp}} Q(\Pi g) = \sqrt[2]{\text{supp}} T(g) \). We can then conclude applying Lemma 3.6.

Corollary 3.8. Let \( Q = Q(g) \). Suppose that \( S(g) \subset \mathcal{V}_k(h) \) and \( \frac{\|X\|}{\text{supp} Q} \leq 1 \). Then for every \( t_0 \geq \deg h \) there exists \( t_1 \geq t_0 \) such that \( (h)_{t_1} \subset Q_{t_1}(g) \). In this case:

\[
L_{t_1}(g)[t_0] \subset L_{t_1}(h),
\]

and in particular this holds when \( (h) = I(S(g)) \).

Moreover, \( L_{t_1}(g)[t_0+k] \subset L_{t_1+k}(h) \) for all \( k \in \mathbb{N} \).

Proof. We prove it as Corollary 3.7 using [Mar08], cor. 7.4.2 (3):

\[
\dim \frac{\mathbb{R}[X]}{\text{supp} \mathcal{Q}(g)} \leq 1 \Rightarrow \mathcal{I}(S(g)) = \sqrt[2]{\text{supp} \mathcal{Q}(g)}
\]

instead of the Real Nullstellensatz.

We conclude this section discussing how the closure properties of truncated quadratic modules are related with strong duality for Lasserre’s hierarchies. We briefly recall existing results in this direction.

Theorem 3.9 (Strong duality). Let \( Q = Q(g) \) be a quadratic module and \( f \) the objective function. Then:

(i) if \( \text{supp} Q = \{0\} \) then \( \forall d: f_{\text{SoS,d}}^* \) is attained (i.e. \( f - f_{\text{SoS,d}}^* \in Q_{d}(g) \)) and \( f_{\text{SoS,d}}^* = f_{\text{MoM,d}}^* \) [Mar08, Prop. 10.5.1];

(ii) if for some \( r \in \mathbb{R}, r^2 - \|X\|^2 \in g \) then \( f_{\text{SoS,d}}^* = f_{\text{MoM,d}}^* \) for all \( d \) [H16].
Remark. [JH16] applies when the ball constraint $r^2 - \|X\|^2$ appears explicitly in the description of $S$. But if we consider a problem with MoM finite convergence and such that $Q(g)$ is Archimedean, then we can use [JH16] to prove that we have also SoS finite convergence. Indeed, if $Q(g)$ is Archimedean there exists $r, t$ such that $r^2 - \|X\|^2 \in Q_{2d}(g)$. This means that $Q_{2d}(g, r^2 - \|X\|^2) \subset Q_{2d+2d}(g)$. If we define:

\[
\begin{align*}
  f_{\text{SoS}, d} & = \sup \{ \lambda \in \mathbb{R} \mid f - \lambda \in Q_{2d}(g) \} \\
  f_{\text{SoS}, d}^* & = \sup \{ \lambda \in \mathbb{R} \mid f - \lambda \in Q_{2d}(g, r^2 - \|X\|^2) \}
\end{align*}
\]

and $f_{\text{MoM}, d}, f_{\text{MoM}, d}^*$ the corresponding MoM relaxations, then:

\[ f_{\text{MoM}, d} \leq f_{\text{MoM}, d}^* = f_{\text{SoS}, d}^* \leq f_{\text{SoS}, d+t} \leq f^*. \]

Then finite convergence of the MoM hierarchy implies finite convergence of the SoS one.

We now prove a strong duality result, that will be useful to analyze finite convergence and exactness in Appendix A. This result, very similar to a result in [Mar03], generalizes the condition $\text{supp } Q = (0)$ in Theorem 3.9.

For this generalization, we need the definition of graded basis. We say that $h$ is a graded basis of $I = (h)$ if $(h)_t = I_t \cap \mathbb{R}[X]$ for all $t \in \mathbb{N}$, where $(h)_t$ denotes the vector space of polynomials in $I = (h)$ generated in degree $\leq t$. For instance, any Groebner basis with respect to an ordering compatible with the total degree is a graded basis.

**Proposition 3.10.** Let $Q = Q(g)$ be a finitely generated quadratic module, and let $h$ be a graded basis of $\sqrt{\text{supp } Q}$. Then for any $d$ we have that $Q_d(g, \pm h) = Q_d(g, \pm h)$ is closed. Moreover, if $S(g) \neq \emptyset$ and we consider the relaxations $Q_{2d}(g, \pm h)$ and $L_{2d}(g, \pm h)$ (extensions of $Q_{2d}(g)$ and $L_{2d}(g)$ using the generators of $\sqrt{\text{supp } Q}$), then for any $f \in \mathbb{R}[X]$, there is no duality gap: $f_{\text{SoS}, d}^* - f_{\text{MoM}, d}^* = 0$. In this case, if $f_{\text{SoS}, d}^* > -\infty$, then $f_{\text{SoS}, d}^*$ is attained (i.e. $f - f_{\text{SoS}, d}^* \in Q_{2d}(g, \pm h)$).

**Proof.** Consider the quotient map $\phi: \mathbb{R}[X]_{2d} \to \mathbb{R}[X]_{2d}/I_{2d}$. By [Mar08] Lem. 4.1.4, the image of $Q_{2d}(g, \pm h)$ under $\phi$ is closed. Since $h$ is a graded basis, $\phi^{-1}(\phi(Q_{2d}(g, \pm h))) = Q_{2d}(g, \pm h) + I_{2d} = Q_{2d}(g) + (\pm h)_{2d}$. Therefore, $Q_{2d}(g, \pm h)$ is closed as well. Therefore we have $L_{2d}(g, \pm h) = (Q_{2d}(g, \pm h))_{\text{ext}} = Q_{2d}(g, \pm h)$, from which we deduce that there is no duality gap, by classical convexity arguments, as follows.

If $f \in \mathbb{R}[X]$ and $S(g) \neq \emptyset$, let $H = \{ a \in \mathbb{R} \mid f - a \in Q_{2d}(g, \pm h) \}$. By construction, $H$ is empty or an interval unbounded from below. We prove now that it is always bounded from above. Since $S(g) \neq \emptyset$ then $f^* < +\infty$, and for all $a > f^*$ there exists $x \in S(g)$ such that $f(x) < a$. Then $f(x) - a < f(x) - f^*$, and thus $f - a \notin Q_{2d}(g, \pm h)$ and $a \notin H$. Therefore $H$ is bounded from above.

If $H = \emptyset$, then $f_{\text{SoS}, d}^* = \sup H = -\infty$. If $f_{\text{MoM}, d}^* > -\infty$, then $\exists m \in \mathbb{R}$ such that $\langle \lambda, f \rangle \geq -m > -\infty$ for all $\lambda \in L_{2d}(g, \pm h)$. Using [Bal22] Lem. 1.3.9, we deduce that $\langle \lambda, f + M \rangle \geq 0$ for all $\lambda \in L_{2d}(g, \pm h)$, and thus $f + M \in L_{2d}(g, \pm h) = L_{2d}(g, \pm h)$, a contradiction to $H = \emptyset$. Therefore, $f_{\text{MoM}, d}^* = -\infty = f_{\text{SoS}, d}^*$.

If $H \neq \emptyset$, since $Q_{2d}(g, \pm h)$ is closed and $H$ bounded from above, $f_{\text{SoS}, d}^* = \sup H = \sup \{ a \in \mathbb{R} \mid f - a \in Q_{2d}(g, \pm h) \}$ is attained. If $f_{\text{SoS}, d}^* < f_{\text{MoM}, d}^*$, then $f - f_{\text{MoM}, d}^* \notin Q_{2d}(g, \pm h)$. Thus there exists a separating functional $\lambda \in L_{2d}(g, \pm h)$ such that $\langle \lambda, f - f_{\text{MoM}, d}^* \rangle < 0$, which implies that $\langle \lambda, f \rangle < f_{\text{MoM}, d}^*$ in contradiction with the definition of $f_{\text{MoM}, d}^*$. Consequently, $f_{\text{SoS}, d}^* = f_{\text{MoM}, d}^*$.

Finally, if $f_{\text{SoS}, d}^* > -\infty$ then $H \neq \emptyset$, and we can conclude as before that $f_{\text{SoS}, d}^*$ is attained. \qed
3.2 Annihilators of truncated moment sequences

Recall that the annihilator \( \text{Ann}_t(\lambda) \) is the kernel of the moment matrix of \( \lambda \) in degree \( \leq t \) (or of the Hankel operator). With the characterization of \( \mathcal{Q} \) we can now describe these kernels of moment matrices associated to truncated positive linear functionals.

We recall the definition of genericity in the truncated setting and equivalent characterizations.

**Definition 3.11.** Let \( C \subset \mathbb{R}[X]_d \) be a convex set. We say that \( \lambda^* \in C \) is generic in \( C \) if \( \text{rank} H_{\lambda^*}^\frac{d}{2} = \max \{ \text{rank} H_{\eta}^\frac{d}{2} \mid \eta \in C \} \).

In particular, we will consider generic \( \lambda^* \) in the following convex sets, which are used in polynomial optimization:

- \( C = \mathcal{L}_{2d}(g) \), the cone of positive linear functionals or feasible pseudo-moment sequences of Lasserre’s moment relaxation of order \( d \);
- \( C = \mathcal{L}_{2d}(1)(g) \), the convex set defined as the section of \( \mathcal{L}_{2d}(g) \) given by \( \langle \lambda, 1 \rangle = 1 \);
- \( C = \mathcal{L}_{2d}^{\min}(f; g) \), the exposed face of \( \mathcal{L}_{2d}(1)(g) \) defined by \( \langle \lambda, f \rangle = f^* \);
- \( C = \mathcal{L}_{2d}(g)^{2k}, \mathcal{L}_{2d}(1)(g)^{2k}, \mathcal{L}_{2d}^{\min}(f; g)^{2k} \), the restrictions of the positive linear functionals of the above sets to \( \mathbb{R}[X]_{2k} \).

We will use generic linear functionals to recover the minimizers when we have the flat truncation property. They can be characterized as follows, see [Las+13, Prop. 4.7] and [Bal22, Prop. 3.4.10].

**Proposition 3.12.** Let \( C \) be a convex subset of \( \mathcal{L}_d(g) \) and let \( \lambda \in C \). The following are equivalent:

(i) \( \lambda \) is generic in \( C \);

(ii) \( \text{Ann}_{\frac{d}{2}}(\lambda) \subset \text{Ann}_{\frac{d}{2}}(\eta) \forall \eta \in C \);

(iii) \( \forall k \leq d, \text{ we have: } \text{rank} H_{\lambda}^\frac{d}{2} = \max \{ \text{rank} H_{\eta}^\frac{d}{2} \mid \eta \in C \}, i.e. \lambda^k \) is generic in \( C^k \).

**Remark.** By Proposition 3.12 notice that \( \forall d' \leq d, \text{ if } \lambda^* \in \mathcal{L}_d(g) \) is generic then \( (\lambda^*)^{d'} \) is generic in \( \mathcal{L}_{d}(g)^{[d']} \). In particular, \( \text{Ann}_{\frac{d+1}{2}}(\lambda^*) \subset \text{Ann}_{\frac{d+1}{2}}(\eta) \forall \eta \in \mathcal{L}_d(g) \).

We can show that any convex linear functional in the relative interior is generic.

**Lemma 3.13.** Let \( C \) be a convex subset of \( \mathcal{L}_d(g) \). Then any linear functional \( \lambda \) in the relative interior of \( \mathcal{L}_d(g) \) is generic in \( C \).

**Proof.** Let \( \lambda \) be in the relative interior of \( C \). For any \( \lambda_1 \in C \), there exists \( \lambda_2 \in C \) and \( a_1, a_2 \in \mathbb{R}_{>0} \) with \( a_1 + a_2 = 1 \), such that \( \lambda = a_1 \lambda_1 + a_2 \lambda_2 \).

Denote \( k = [\frac{d}{2}] \). The inclusion

\[
\text{Ann}_k(\lambda) = \ker H_k^\lambda = \ker H_{a_1 \lambda_1 + a_2 \lambda_2} ^k \supset \ker H_{\lambda_1}^k \cap \ker H_{\lambda_2}^k = \text{Ann}_k(\lambda_1) \cap \text{Ann}_k(\lambda_2)
\]

is direct. Conversely, if \( f \in \text{Ann}_k(\lambda) \) then \( f \star \lambda = a_1 (f \star \lambda_1) + a_2 (f \star \lambda_2) = 0 \). In particular,

\[
0 = (f \star \lambda, f) = a_1 (f \star \lambda_1, f) + a_2 (f \star \lambda_2, f) = a_1 \langle \lambda_1, f^2 \rangle + a_2 \langle \lambda_2, f^2 \rangle
\]

Therefore \( \langle \lambda_1, f^2 \rangle = \langle \lambda_2, f^2 \rangle = 0 \), and from [Las+13, Lem. 3.12] we have \( f \in \text{Ann}_d(\lambda_1) \cap \text{Ann}_d(\lambda_2) \), proving the reverse inclusion. We deduce that \( \forall \lambda \in C \) we have \( \text{Ann}_k(\lambda) \subset \text{Ann}_k(\lambda_1) \), thus \( \lambda \) is generic from Proposition 3.12.

\( \square \)
As any point in the relative interior of \( C \) is generic in \( C \) by Lemma 3.13 in practice generic linear functionals can be recovered from SDP solvers based on interior point methods. Indeed, these solvers approximately follow the central path to get an approximately optimal solution (possibly using a self-dual-embedding or facial reduction) of the original SDP problem, see e.g. [HKR02] and references therein. Therefore, using an SDP solver based on interior point methods we can approximately get a point in the relative interior (see also [LLR08, Sec. 4.4.1]). Notice also that there are examples of cones \( C \subset L_d(\mathbf{g}) \) where extreme points are generic in \( C \), see Example 4.2.

We are now ready to describe the annihilator of these generic elements.

**Theorem 3.14.** If \( d,t \in \mathbb{N} \) are big enough and \( \lambda^* \in L_d(\mathbf{g}) \) is generic, we have \( \sqrt{\text{supp} \mathbf{g}} = (\text{Ann}_t(\lambda^*)) \). Moreover if \( Q(\mathbf{g}) = T(\mathbf{g}) \) is a preordering, then \( (\text{Ann}_t(\lambda^*)) = \mathcal{I}(S(\mathbf{g})) \).

**Proof.** We denote \( J = \sqrt{\text{supp} \mathbf{g}} \). Let \( t \in \mathbb{N} \) be such that \( J \) is generated in degree \( \leq t \), by the graded basis \( h = h_1, \ldots, h_s \) (see above Proposition 3.10 for the definition). From Lemma 3.3 we deduce that there exists \( d \in \mathbb{N} \) such that \( J_d \subset Q_d(\mathbf{g}) \). Let \( \lambda^* \in L_d(\mathbf{g}) \) be generic.

We first prove that \( J \subset (\text{Ann}_t(\lambda^*)) \). By Proposition 3.12 we have \( \text{Ann}_t(\lambda^*) = \bigcap_{\lambda \in L_d(\mathbf{g})} \text{Ann}_t(\lambda) \). Then it is enough to prove that \( J \subset \text{Ann}_t(\lambda) \) for all \( \lambda \in L_d(\mathbf{g}) \).

By Lemma 3.6 \( L_d(\mathbf{g})^{[2]} \subset L_{2d}(\pm h) \subset (h)_{2d}^\perp \). Then \( \forall f \in J = \langle h_1 \rangle, \forall p \in \mathbb{R}[X]_l, \forall \lambda \in L_d(\mathbf{g}) \), we have \( \langle f, p \rangle = 0 \). This shows that \( H^t_j(f)(p) = \langle (f \star \lambda)^t, p \rangle = 0 \), i.e. \( \langle f, p \rangle = 0 \), for \( f \in \text{Ann}_t(\lambda) = \ker H^t_j \).

Conversely, we show that \( (\text{Ann}_t(\lambda^*)) \subset J \) for \( \lambda^* \) generic in \( L_d(\mathbf{g}) \). Since \( J = \sqrt{\text{supp} \mathbf{g}} = \text{supp} \cup_j Q_j(\mathbf{g}) \) (by Theorem 3.4) it is enough to prove that \( \text{Ann}_t(\lambda^*) \subset Q_d(\mathbf{g}) \) for all \( \lambda \in L_d(\mathbf{g}) \).

Let \( f \in \text{Ann}_t(\lambda^*) = \bigcap_{\lambda \in L_d(\mathbf{g})} \text{Ann}_t(\lambda) \) (we use again Proposition 3.12) and let \( \lambda \in L_d(\mathbf{g}) \). Then \( \langle \lambda, f \rangle = \langle (f \star \lambda)^t, 1 \rangle = H^t_j(f)(1) = 0 \). In particular \( f \in L_d(\mathbf{g})^\perp \). We prove that \( -f \in L_d(\mathbf{g})^\perp \) in the same way. Then \( f \in L_d(\mathbf{g})^\perp \). Then \( J = L_d(\mathbf{g})^\perp = \bigcap_{\lambda \in L_d(\mathbf{g})} \text{Ann}_t(\lambda) \), and we conclude from Definition 3.11 and Theorem 3.4 that \( \text{Ann}_t(\lambda^*) \subset \text{supp} \mathbf{g} = J \).

The second part follows from the first one and the Real Nullstellenatz. \( \square \)

Theorem 3.14 generalizes the results of [LLR08] for equations defining real algebraic varieties. In [LLR08], in the zero-dimensional case the flat truncation criterion is used to detect equality between the ideal generated by the annihilator (or by the kernel of the moment matrix) and the real radical of the equations. As explained in Theorem 3.18 we cannot use flat truncation to detect equality in the positive dimensional case. Other techniques to verify that \( t,d \) are big enough to generate the real radical of the support have been further investigated in [Bal22, Ch. 4] and [BM21].

Theorem 3.14 shows the possibilities and the limits of MoM hierarchies. For instance we cannot expect exactness of the MoM relaxation \( L_{2d}(\mathbf{g}) \) for any objective function \( f \) (i.e. \( L_{2d}(\mathbf{g})^{[k]} \subset \mathcal{M}(S)^{[k]} \)) if \( \sqrt{\text{supp} \mathbf{g}} / \mathcal{I}(S)\) see Example A.6.

### 3.3 Interpolation degree and flat truncation

In this section, we analyze the properties of moment sequences in \( L_d(\mathbf{g}) \) when \( S = S(\mathbf{g}) \) is finite. We will use the results in this section to study the case of finitely many minimizers in Polynomial Optimization Problems, and in particular the flat truncation property.

Let \( \Xi = \{ \xi_1, \ldots, \xi_r \} \in \mathbb{C}^n \) be a finite set of (complex) points and let \( \mathcal{I}(\Xi) = \{ p \in \mathbb{C}[X] | p(\xi_i) = 0 \ \forall i \in 1, \ldots, r \} \) be the complex vanishing ideal of the points \( \Xi \). It is well known (see e.g. [Eis05]) that \( \Xi \) admits a family of interpolator polynomials \( \{ u_i \} \subset \mathbb{C}[X] \) such that \( u_i(\xi_j) = \delta_{i,j} \), which form a basis \( \mathbb{C}[X] / \mathcal{I}(\Xi) \). The minimal degree of a family of interpolator polynomials is called the interpolation degree of \( \Xi \) and denoted \( \theta(\Xi) \).

A classical result states that \( \theta(\Xi) + 1 \) is the Castelnuovo-Mumford regularity of the ideal \( \mathcal{I}(\Xi) \) (see [Eis05, Th. 4.1]). This interpolation degree \( \theta(\Xi) \) is the minimal degree of a basis of \( \mathbb{C}[X] / \mathcal{I}(\Xi) \). It is also the minimal degree of a monomial basis \( B \) of \( \mathbb{R}[X] / \mathcal{I}(\Xi) \). Such a minimal degree basis \( B \) can be
We say that the flat truncation is the dual basis of \( \text{annihilator} \) (or, of the kernel of the moment matrix) as the full truncated vanishing ideal of the points, truncated above twice the interpolation degree are represented by (positive) measures. Recall that if \( I \) is an ideal we denote \( I_t = I \cap \mathbb{R}[X]_t \) and \( \langle \cdot \rangle \) denotes the linear span of a set.

**Proposition 3.15.** Let \( \Xi = \{\xi_1, \ldots, \xi_r\} \subset \mathbb{R}^n \), \( I = I(\Xi) \) its real vanishing ideal and let \( \theta = \theta(\Xi) \) the interpolation degree of \( \Xi \). Let \( t \geq \theta \) and \( \lambda \in \mathbb{R}[X]_t \). Then \( \lambda \in I_{t+2}^{1} \) if and only if \( \lambda \in \langle e_{\xi_1}^{[t]}, \ldots, e_{\xi_r}^{[t]} \rangle \). Moreover if \( t \geq 2\theta \) and \( \lambda \in \mathcal{L}_t(I_{t}) \), then \( \lambda \in \text{cone}(e_{\xi_1}^{[t]}, \ldots, e_{\xi_r}^{[t]}) \) and \( \text{rank } H_{\lambda}^{t+2} \leq r \).

**Proof.** Let \( u_1, \ldots, u_r \in \mathbb{R}[X]_t \) be interpolation polynomials of degree \( \theta \leq t \). Consider the sequence of vector space maps:

\[
0 \to I_t \to \mathbb{R}[X]_t \xrightarrow{\psi} \langle u_1, \ldots, u_r \rangle \to 0
\]

which is exact since \( \ker \psi = \{p \in \mathbb{R}[X]_t | p(\xi_i) = 0\} = I_t \). Therefore we have \( \mathbb{R}[X]_t = \langle u_1, \ldots, u_r \rangle \oplus I_t \).

Let \( \lambda \in I_{t+2}^{1} \). Then \( \tilde{\lambda} = \lambda - \sum_{i=1}^{r} (\lambda, u_i) e_{\xi_i}^{[t]} \in I_{t}^{1} \) is such that \( \langle \tilde{\lambda}, u_i \rangle = 0 \) for \( i = 1, \ldots, r \). Thus, \( \tilde{\lambda} \in \langle u_1, \ldots, u_r \rangle^{\perp} \cap I_{t}^{1} = (\langle u_1, \ldots, u_r \rangle \oplus I_t)^{\perp} = \mathbb{R}[X]_t \), i.e. \( \tilde{\lambda} = 0 \) showing that \( I_{t}^{1} \subset \langle e_{\xi_1}^{[t]}, \ldots, e_{\xi_r}^{[t]} \rangle \). The reverse inclusion is direct since \( I_t \) is the space of polynomials of degree \( \leq t \) vanishing at \( \xi_i \) for \( i = 1, \ldots, r \).

Assume now that \( t \geq 2\theta \) and \( \lambda \in \mathcal{L}_t(I_{t}) \). Then \( \lambda \in I_{t+2}^{1} \) and \( \langle \lambda, p^2 \rangle \geq 0 \) for any \( p^2 \in \mathbb{R}[X]_t \). By the previous analysis,

\[
\lambda = \sum_{i=1}^{r} \omega_i e_{\xi_i}^{[t]}
\]

As \( 0 \leq \langle \lambda, u_i^2 \rangle = \omega_i \) for \( i = 1, \ldots, r \), we deduce that \( \lambda \in \text{cone}(e_{\xi_1}^{[t]}, \ldots, e_{\xi_r}^{[t]}) \).

Let \( s = [\frac{1}{2}] \). We verify that the image of \( H_{\lambda}^{s} : p \in \mathbb{R}[X]_s \mapsto \sum_{i=1}^{r} \omega_i p(\xi_i) e_{\xi_i}^{[s]} \) is included in \( \langle e_{\xi_1}^{[s]}, \ldots, e_{\xi_r}^{[s]} \rangle \), computing \( H_{\lambda}^{s}(u_i) \) for \( i = 1, \ldots, r \). Thus \( \text{rank } H_{\lambda}^{s} \leq \text{dim}(e_{\xi_1}^{[s]}, \ldots, e_{\xi_r}^{[s]}) = r \) since \( e_{\xi_i}^{[s]} \) is the dual basis of \( (u_i)_{i=1, \ldots, r} \).

We describe now a property, known as flat truncation, which allows to test effectively if truncated moment sequences are represented by sums of point evaluations.

**Definition 3.16** (Flat truncation, [Lau09 Th. 6.18], [Nie13b Sec. 1.2]). Let \( d_g = [\frac{1}{2} \max_{i=1, \ldots, d} \deg(g_i)] \). We say that the flat truncation property holds for \( \lambda \in \mathcal{L}_d(g) \) at degree \( t \) if \( t \leq \frac{d}{2} - d_g \) and

\[
\text{rank } H_{\lambda}^{t} = \text{rank } H_{\lambda}^{t+4d_g}.
\]

This definition coincides with the definition of flat truncation given in [Nie13b], and previously exploited in [Lau09]. The flat truncation is a modification of the flat extension criterion by Curto and Fialkov (see e.g. [CF03]), and is very useful in polynomial optimization to certify the finite convergence and to extract the minimizers.

We now investigate in more detail this rank condition for the moment matrix of \( \lambda \in \mathcal{L}_d(g) \). In the following lemma, we reprove and extend known properties associated with flat truncation (see e.g. [Lau09 Th. 5.33] and references therein). Our improvements are the characterization of the annihilator (or, of the kernel of the moment matrix) as the full truncated vanishing ideal of the points, and a truncation degree for which all the linear functionals coincide with sums of point evaluations.

\[\text{i.e. if } m m' \in B \text{ then } m \in B \text{ and } m' \in B\]
Lemma 3.17. If \( \lambda \in \mathcal{L}_d(\mathfrak{g}) \) is such that \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+s} = r \) with \( t + 1 \leq t + s \leq \frac{d}{2} \), then
\[
\lambda^{[t+s+\frac{1}{2}]} = \omega_1 \mathbf{e}_{\xi_1}^{[t+s+\frac{1}{2}]} + \cdots + \omega_r \mathbf{e}_{\xi_r}^{[t+s+\frac{1}{2}]}
\]
for some points \( \xi_i \in \mathbb{R}^n \) and weights \( \omega_i > 0, \) \( i = 1, \ldots, r. \) Denoting \( \Xi = \{ \xi_1, \ldots, \xi_r \} \), we also have \( \text{Ann}_{t+s}(\lambda) = \mathcal{I}(\Xi)_{t+s} \) and \( \forall(\text{Ann}_{t+s}(\lambda)) = \Xi \) (or, in other words, \( \text{Ann}_{t+s}(\lambda) = \mathcal{I}(\Xi) \)).

Moreover, if \( t \leq \frac{d}{2} + s - \text{deg}(\mathfrak{g}) \), where \( \text{deg}(\mathfrak{g}) = \max_{i=1,\ldots,s} \text{deg}(g_i) \), the inclusion \( \Xi \subset S(\mathfrak{g}) \) holds true.

Proof. From [Lau09, Th. 5.29], there exists unique \( \lambda \in \{ \xi_1, \ldots, \xi_r \} \subset \mathbb{R}^n \) and \( \omega_1, \ldots, \omega_r > 0 \) such that \( \lambda^{[2(t+s)]} = \omega_1 \mathbf{e}_{\xi_1}^{[2(t+s)]} + \cdots + \omega_r \mathbf{e}_{\xi_r}^{[2(t+s)]} \), \( \text{Ann}_{t+s}(\lambda) = \mathcal{I}(\Xi) \) and \( \forall(\text{Ann}_{t+s}(\lambda)) = \Xi \). In particular \( \text{Ann}_{t+s}(\lambda) \) is a zero-dimensional ideal and \( \text{Ann}_{t+s}(\lambda) \subset \mathcal{I}(\Xi)_{t+s} \). Conversely, for any \( h \in \mathcal{I}(\Xi)_{t+s} \), we have
\[
\langle \lambda, h^2 \rangle = \langle \lambda^{[2(t+s)]}, h^2 \rangle = \sum_{i=1}^r \omega_i \langle \mathbf{e}_{\xi_i}^{[2(t+s)]}, h^2 \rangle = \sum_{i=1}^r \omega_i h^2(\xi_i) = 0.
\]
Thus \( h \in \text{Ann}_{t+s}(\lambda) \) (see [Las+13, Lem. 3.12]) and \( \mathcal{I}(\Xi)_{t+s} = \text{Ann}_{t+s}(\lambda) \).

As \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+s} = r \), we deduce from above, that \( \text{Ann}_{t+s}(\lambda) = \mathcal{I}(\Xi) \) is generated in degree \( t + 1 \) and that \( \theta(\Xi) \leq t \). Therefore \( \Xi \) has an interpolar polynomials \( u_1, \ldots, u_r \) of degree \( \leq t \).

Let us show that the description of \( \lambda \) on polynomials of degree \( \leq 2(t+s) \) can be extended to higher degree. For any \( h \in \text{Ann}_{t+s}(\lambda) = \mathcal{I}(\Xi)_{t+s} \), \( \mathfrak{g} \) i.e. such that \( \langle \lambda, h^2 \rangle = 0 \), and any \( p \in \mathbb{R}[X]_{\frac{d}{2}} \), we have \( \langle \lambda, hp \rangle = 0 \). This shows that \( \lambda \in (\mathcal{I}(\Xi)_{t+s+\frac{1}{2}})^\perp \). We deduce from Proposition 3.15 that \( \lambda^{[t+s+\frac{1}{2}]} \in \text{cone}(\mathbf{e}_{\xi_1}, \ldots, \mathbf{e}_{\xi_r})_{t+s+\frac{1}{2}} \). This implies that \( \lambda^{[t+s+\frac{1}{2}]} = \omega_1 \mathbf{e}_{\xi_1}^{[t+s+\frac{1}{2}]} + \cdots + \omega_r \mathbf{e}_{\xi_r}^{[t+s+\frac{1}{2}]} \), evaluating \( \langle \lambda, u_i \rangle = \langle \lambda^{[t+s+\frac{1}{2}]}, u_i \rangle = \omega_i \) at the interpolar polynomials \( u_1, \ldots, u_r \) of \( \Xi \) of degree \( \leq t \).

We show now that \( \Xi = \{ \xi_1, \ldots, \xi_r \} \subset S(\mathfrak{g}) \) if \( t \leq \frac{d}{2} + s - \text{deg}(\mathfrak{g}) \). For \( i = 1, \ldots, r \) and \( j = 1, \ldots, m \) the polynomial \( u_i^2 g_j \) has degree \( 2t + \text{deg}(\mathfrak{g}) \leq t + s + \frac{d}{2} \). Then we obtain:
\[
0 \leq \langle \lambda, u_i^2 g_j \rangle = \langle \lambda^{[t+s+\frac{1}{2}]}, u_i^2 g_j \rangle = \langle \omega_1 \mathbf{e}_{\xi_1}^{[t+s+\frac{1}{2}]} + \cdots + \omega_r \mathbf{e}_{\xi_r}^{[t+s+\frac{1}{2}]}, u_i^2 g_j \rangle = \omega_i g_j(\xi_i),
\]
showing that \( g_j(\xi_i) \geq 0 \) for all \( i \) and \( j \), i.e. \( \Xi \subset S(\mathfrak{g}) \).

Remark. Lemma 3.17 can be used to test flat truncation in a simpler way when \( d \) is big, as we explain in the following. Assume for simplicity that \( 2d_\mathfrak{g} = \text{deg}(\mathfrak{g}) \). Then, if \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+s} \) with \( t \leq \frac{d}{2} + s - \text{deg}(\mathfrak{g}) \), we have \( 2(t + d_\mathfrak{g}) = 2t + \text{deg}(\mathfrak{g}) \leq t + s + \frac{d}{2} \). Then from Lemma 3.17 we deduce that \( \lambda \) restricted to polynomials of degree \( \leq 2(t + d_\mathfrak{g}) \) is equal to a sum of evaluations at points of \( S \) with positive weights, and the flat truncation is satisfied: \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+d_\mathfrak{g}} \). In particular, when \( s = 1 \) and \( d \geq 2t - 2 + 2 \text{deg}(\mathfrak{g}) \), \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+1} \) implies \( \text{rank } H_\lambda^t = \text{rank } H_\lambda^{t+d_\mathfrak{g}} \).

We now show that we can use flat truncation for generic linear functionals to describe semialgebraic sets with a finite number of points. Results similar to Theorem 3.18 and Theorem 3.19 have been already studied in [LLR08, Las+13]: we discuss in detail the differences with previous results after Theorem 3.19.

Theorem 3.18. If a positive linear functional \( \lambda^* \in \mathcal{L}_d(\mathfrak{g}) \) is such that \( (\lambda^*)^{[2(t+d_\mathfrak{g})]} \) is generic in \( \mathcal{L}_d(\mathfrak{g})^{[2(t+d_\mathfrak{g})]} \) (that is \( \text{Ann}_{t+d_\mathfrak{g}}(\lambda^*) \subset \text{Ann}_{t+d_\mathfrak{g}}(\lambda) \) for all \( \lambda \in \mathcal{L}_d(\mathfrak{g})^{[2(t+d_\mathfrak{g})]} \)) and \( \lambda^* \) satisfies the flat truncation property at degree \( t \leq \frac{d}{2} - d_\mathfrak{g} \), then:

(i) \( S = S(\mathfrak{g}) = \{ \xi_1, \ldots, \xi_r \} \) is non-empty and finite;

(ii) \( \mathcal{L}_d(\mathfrak{g})^{[t+d_\mathfrak{g}+\frac{1}{2}]} = \text{cone}(\mathbf{e}_{\xi_1}, \ldots, \mathbf{e}_{\xi_r})^{[t+d_\mathfrak{g}+\frac{1}{2}]} \);

(iii) \( t \geq \theta(\xi_1, \ldots, \xi_r) \) and \( \text{Ann}_{t+1}(\lambda^*) = \mathcal{I}(\xi_1, \ldots, \xi_r)_{t+1} = \mathcal{I}(S)_{t+1} \) is the vanishing ideal of \( S \) truncated in degree \( t + 1 \).
Theorem 3.19. Suppose that \( \dim \frac{\mathbb{R}[X]}{\text{supp}\, Q(g)} = 0 \). Then \( S = S(g) \) is finite and there exists \( d \geq 2(\theta + d_g) \) such that \( I(S)_{2(\theta + d_g)} \subset \text{supp}\, Q(g) \), where \( \theta = \theta(S) \) is the interpolation degree of \( S \), and for any \( \lambda \in L_d(g) \) the flat truncation property holds at degree \( \theta \).

Proof. Let \( I = \text{supp}\, Q(g) \) and \( J = \frac{\mathbb{R}[X]}{\text{supp}\, Q(g)} \), and recall that \( J = \sqrt{I} \), see e.g. \cite{Mar08}. We deduce that \( \dim \frac{\mathbb{R}[X]}{J} = \dim \frac{\mathbb{R}[X]}{I} = 0 \) and by 4 we have \( I(S(g)) = \sqrt{\text{supp}\, Q(g)} = J \). Then \( V_\mathbb{R}(J) = V_\mathbb{R}(I(S(g))) = S(g) = \{\xi_1, \ldots, \xi_r\} \) is finite.
We choose a graded basis $\mathbf{h}$ of $J$ with $\deg \mathbf{h} \leq \theta + 1$. By Corollary 3.18 there exists $d \in \mathbb{N}$ such that $I(S)_{2(\theta + d_g)} \subset \supp \overline{Q}_d(g)$. From Corollary 3.18 and Proposition 3.15 we deduce that positive linear functionals in $L_d(g)$ restricted to degree $\leq 2(\theta + d_g)$ are conical sums of evaluations at $\xi_1, \ldots, \xi_r$:

$$L_d(g)^{[2(\theta + d_g)]} \subset L_2(\theta + d_g)(\pm \mathbf{h}) = L_2(\theta + d_g)(I_2(\theta + d_g)) = \text{cone}(e_{\xi_1}, \ldots, e_{\xi_r})^{[2(\theta + d_g)]},$$

and for all $\lambda \in L_d(g)$, we have $\text{rank} H_\lambda^{\theta + d_g} = \text{rank} H_\lambda^{\theta + d_g}$, since

$$\lambda^{[2(\theta + d_g)]} = \sum_{j=1}^{\text{rank} H_\lambda^{\theta + d_g}} \omega_{\xi_j} e_{\xi_j}^{[2(\theta + d_g)]}$$

with $\omega_{\xi_j} > 0$.

Theorem 3.19 says that if $\dim \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(g)} = 0$ then the minimal order for which we have flat truncation is not bigger than $d \geq 2(\theta + d_g)$ such that $I(S)_{2(\theta + d_g)} \subset \supp \overline{Q}_d(g)$. This degree is related to the minimal $d$ for which $I(S) = \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(g)}$ is generated by $\supp \overline{Q}_d(g)$, that is, the minimal degree $d$ such that $I(S)^{\theta + d_g} \subset \text{Ann}_{d}((\lambda^*)^t)$ for a generic $\lambda^* \in L_d(g)$. Moreover, as in the remark after Lemma 3.17 we can replace $\theta + d_g$ with $\theta + 1$ if $d$ is big enough.

Theorem 3.18 and Theorem 3.19 show that if $\dim \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(g)} = 0$ then $S$ is a finite set of points and for a high enough degree $d$, all moment sequences in $L_d(g)$, truncated in degree twice the interpolation degree are represented by a weighted sum of Dirac measures at these points. In particular, it is possible to recover all the points in $S$ from a generic truncated moment sequence, see [HL05], [ABM15] and [Mou18].

Results related to Theorem 3.19 and Theorem 3.18 were obtained in [LLR08] and [Las+13], where they focus on the case of equations $\mathbf{h}$ defining a finite real variety. They prove that, for $d$ big enough and for every positive linear functional $\lambda \in L_d(\pm \mathbf{h})$, the flat truncation property holds for $H_\lambda$ and that $\lambda^{[2d]}$ is a conic combination of evaluations at the points of $\bigcap_{\mathbf{g}} \mathcal{H}(\mathbf{g})$. This can be deduced from Theorem 3.19 since in the case where $\bigcap_{\mathbf{g}} \mathcal{H}(\mathbf{g}) = \{\xi_1, \ldots, \xi_r\}$ is non-empty and finite, $\dim \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(\mathbf{h})} = 0$. Theorem 3.18 generalizes [LLR08] Prop. 4.5, since our result does not assume any explicit equality constraints, emphasizes the role of the support of the quadratic module and the interpolation degree, and provides better degree bounds for the flat truncation degree. Theorem 3.19 analogously generalizes [LLR08] Prop. 4.6. These generalizations are crucial for the characterization of flat truncation in Theorem 4.4, and for Corollary 4.8.

In [LLR08, Rem. 4.9] the authors also mention that their results can be proved for a preordering defining a finite semialgebraic set. This result can be deduced directly from Theorem 3.19 since when $S = S(\mathbf{g}) = \{\xi_1, \ldots, \xi_r\}$ is non-empty and finite, we have by the Real Nullstellensatz, $\dim \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(\mathbf{g})} = \dim \frac{\mathbb{R}[X]}{\supp \overline{Q}_{d}(\mathbf{g})} = \dim \frac{\mathbb{R}[X]}{I(S(\mathbf{g}))} = 0$.

But Theorem 3.19 is even more general, as shown by the following example of a quadratic module, whose support is zero-dimensional, but it is not a preordering.

**Example 3.20 ([Mar08, Ex. 7.4.5 (1)])**. Let $Q = Q(X, Y, 1 - X, 1 - Y, -X^4, -Y^4) \subset \mathbb{R}[X, Y]$. In this case $\supp Q$, which contains $X^4$ and $Y^4$, is zero-dimensional and $Q$ is not a preordering since $XY \not\in Q$. Theorem 3.19 applies in this case, but the results cannot be deduced from [LLR08] or [Las+13].

As we will see, in Polynomial Optimization Problems, flat truncation implies MoM exactness and thus finite convergence. Moreover, it allows extracting the minimizers from an optimal sequence.

## 4 Flat truncation in polynomial optimization problems

In this section, we analyze when flat truncation occurs in the Polynomial Optimization Problem, which consists of minimizing $f \in \mathbb{R}[X]$ on the basic semialgebraic set $S = S(\mathbf{g})$ where $\mathbf{g} = \{g_1, \ldots, g_s\}$ are finitely many real polynomials.
Recall that we denote $f^*$ the minimum of $f$ on $S$. In the following, we will consider the semialgebraic set $S^\text{min} = S(g, \pm (f - f^*)) = S(g) \cap \{x \in \mathbb{R}^n \mid f(x) = f^*\}$ and assume that it is nonempty.

The interest in flat truncation properties in polynomial optimization arises from two aspects. First, in such a case we can certify finite convergence and exactness of the MoM hierarchy, see Theorem [4.1]. Second, if we have a flat moment matrix we can recover the global minimizers of the problem. For more details on the algorithm to extract the minimizers, we refer the reader to [HL05, ABM15, Mou18].

In the following, we adapt the results of Section 3 to the quadratic module $Q(g, \pm (f - f^*))$ defining the minimizers $S^\text{min}$.

4.1 Flat truncation degree

In the following, we aim at analyzing the degree at which flat truncation holds using the interpolation degree, and we provide the first necessary and sufficient condition for flat truncation (Theorem 4.4). But first, we describe the consequences of flat truncation for generic minimizing linear functionals in Theorem 4.1. This theorem extends related results, e.g. in [Lau09, Nie13b]: we perform a detailed comparison with the existing literature after the proof.

**Theorem 4.1.** Consider the problem of minimizing $f$ on $S(g)$. If the flat truncation property holds for a generic $\lambda^* \in \mathcal{L}^\text{min}_2(f; g)$ at a degree $t$ such that deg($f$) - $d_g - d$ \(\leq d - d_g\), then:

(i) $f^* = f^*_{\text{MoM,d}}$ (i.e. we have MoM finite convergence);

(ii) the set of minimizers $S^\text{min} = \{\xi_1, \ldots, \xi_r\}$ is non-empty and finite;

(iii) $\ker H^{t+1}_\lambda = \text{Ann}_{t+1}(\lambda^*) = \mathcal{I}(S^\text{min})_{t+1}$ (i.e. the kernel of the truncated moment matrix equals the truncated ideal of the minimizers) and $V(\text{Ann}_{t+1}(\lambda^*)) = S^\text{min}$;

(iv) $\mathcal{L}^\text{min}_2(f; g)^{[t+d_g+d]} = \text{cone}(e_\xi_1, \ldots, e_\xi_r)^{[t+d_g+d]}$ (i.e. all the minimizing truncated feasible moment sequences are conic sums of evaluations at the minimizers) and all $\lambda \in \mathcal{L}^\text{min}_2(f; g)$ have flat truncation at degree $t$;

(v) the MoM hierarchy is exact.

**Proof.** Let $\lambda^* \in \mathcal{L}^\text{min}_2(f; g)$ be generic such that rank $H^t_{\lambda^*} = \text{rank} H^{t+d_g}_\lambda \leq t + d_g + d$ and $t + d_g \leq d$. Then by Lemma 3.17, $(\lambda^*)^{[t+d_g+d]} = \sum_{i=1}^r \omega_i e_{\xi_i}^{[t+d_g+d]}$ with $\xi_i \in S = S(g)$, $\omega_i > 0$, $\text{Ann}_{t+1}(\lambda^*) = \mathcal{I}(\xi_1, \ldots, \xi_r)_{t+1} = \mathcal{I}(\Xi)_{t+1}$ and $V(\text{Ann}_{t+1}(\lambda^*)) = \Xi$. Notice that $f(\xi_i) \geq f^*$ since $\xi_i \in S$.

We show now that $S^\text{min} = \Xi$. As $\langle \lambda^*, 1 \rangle = 1$ we have $\sum_{i=1}^r \omega_i = 1$. Moreover $f^*_{\text{MoM,d}} = \langle \lambda^*, f \rangle \leq f^*$ and since deg($f$) $\leq t + d_g + d$ we obtain:

$$f^* \geq \langle \lambda^*, f \rangle = \langle (\lambda^*)^{[t+d_g+d]} f \rangle = \sum_{i=1}^r \omega_i (e_{\xi_i}^{[t+d_g+d]} f) = \sum_{i=1}^r \omega_i f(\xi_i) \geq f^*.$$  

This implies that $f(\xi_i) = f^*$ for $i = 1, \ldots, r$. Therefore $f^* = f^*_{\text{MoM,d}}$ and $S^\text{min} \subseteq \Xi$.

From Proposition 3.12, we have that $\lambda^* \in \mathcal{L}^\text{min}_2(f; g)$ being generic implies that $(\lambda^*)^{[2(t+d_g)]}$ is generic in $\mathcal{L}^\text{min}_2(f; g)^{[2(t+d_g)]}$. Moreover $(\lambda^*)^{[2(t+d_g)]} = \sum_{i=1}^r \omega_i e_{\xi_i}^{[2(t+d_g)]} \in \mathcal{L}^{(1)}_{2d}(g, \pm (f - f^*))^{[2(t+d_g)]}$ since $\Xi \subset S^\text{min} = S(g, \pm (f - f^*))$. Then, as $\mathcal{L}^{(1)}_{2d}(g, \pm (f - f^*)) \subset \mathcal{L}^\text{min}_2(f; g)$ and $(\lambda^*)^{[2(t+d_g)]}$ is generic in $\mathcal{L}^\text{min}_2(f; g)^{[2(t+d_g)]}$, we have

$$\forall \lambda \in \mathcal{L}^{(1)}_{2d}(g, \pm (f - f^*)) \text{ Ann}_{t+d_g}(\lambda^*) \subset \text{Ann}_{t+d_g}(\lambda),$$

i.e. $(\lambda^*)^{[2(t+d_g)]}$ is generic in $\mathcal{L}^{(1)}_{2d}(g, \pm (f - f^*))^{[2(t+d_g)]}$. We can then conclude from Theorem 3.18 that:

- $S^\text{min} = \Xi$;
• \( L_{2d}^{\min}(f; g)[t+d_4+d] = \text{cone}(e_{\xi_1}, \ldots, e_{\xi_r})[t+d_4+d] \);
• \( t \geq \theta(\xi_1, \ldots, \xi_r) \);
• \( \text{supp}(Q(g, \pm(f-f^*)) \) is zero dimensional, since \( \sqrt{\text{supp}(Q(g, \pm(f-f^*)) = \sqrt{\text{supp}(Q(g, \pm(f-f^*))} \) is zero-dimensional.

From Theorem 3.19 applied to \( Q(g, \pm(f-f^*)) \), we deduce that all \( \lambda \in L_{2d}^{\min}(f; g) \) have flat truncation at degree \( t \).

Finally we show MoM exactness. For every \( d' \geq d \) and \( \lambda \in L_{2d}^{\min}(f; g) \), we have \( \lambda[2d] \in L_{2d}^{\min}(f; g) \) since \( \langle \lambda, f \rangle = f^* \). Therefore \( \lambda \) has flat truncation in degree \( t \) and by Lemma 5.17, \( \lambda[t+d_4+d] \) is represented by a convex sum of Dirac measures at points in \( S \) (that are the minimizers \( \xi_1, \ldots, \xi_r \)). This shows that the moment hierarchy is exact, since increasing \( d' \) we increase also the truncation degree where \( \lambda \) coincides with a weighted sum of evaluations at the minimizers, i.e., setting \( k = t + d_g + d' \), we have \( L_{2d}^{\min}(f; g)^[k] \subset M^{(1)}(S(g))[k] \) for all \( d' \). As increasing \( d' \) in the previous inclusion we also increase \( k \), this proves MoM exactness and concludes the proof.

Theorem 4.1 relaxes previous degree conditions. In [Lau09, Th. 6.18], the degree condition to deduce (i) and (ii) in Theorem 4.1 is \( \deg(f) \leq 2t + 2d_g \), which is in general a stronger condition than \( \deg(f) \leq t + d_g + d \) in Theorem 4.1. Theorem 4.1 also shows that the kernel of the moment matrix of a generic truncated moment sequence, \( \text{Ann}_{\lambda^*} \), is the truncated vanishing ideal of the minimizers and that the hierarchy is exact. This means that any element in \( L_{2d}^{\min}(f; g) \) truncated in any degree \( t \) is represented by a measure, provided \( d \geq t \) is big enough. Recall from Section 3 that the points in the relative interior of \( L_{2d}^{\min}(f; g) \) are generic in this convex cone, and thus interior point SDP solvers in practice return approximations of generic linear functionals in \( L_{2d}^{\min}(f; g) \). Theorem 4.1 shows that, if any generic minimizing linear functional has flat truncation at degree \( t \), then all minimizing linear functional have flat truncation at degree \( t \). Similar results have been described in [LLR08, Las+13], but only for the feasibility problem in the zero-dimensional case. This result was not previously described in the general polynomial optimization case (e.g. this statement cannot be found in [Lau09, Th. 6.18]). In [Nie13], it is shown that finite convergence of the hierarchies and flat truncation for all minimizing linear functionals are generically equivalent conditions, but the special properties of generic minimizing linear functionals are not considered (see also the discussion after Theorem 4.4).

A key ingredient in this analysis is Lemma 3.17. From Lemma 3.17 and the remark after it, if \( d \) is big enough the results of Theorem 4.1 hold true, if we replace the condition \( H_{\lambda^*} = \text{rank} H_{\lambda^*} \) with \( \text{rank} H_{\lambda^*} = \text{rank} H_{\lambda^*}^{d_4+1} \).

However, we show in Example 4.2 that the condition \( \text{rank} H_{\lambda^*} = \text{rank} H_{\lambda^*}^{d_4+1} \) is in general not sufficient to conclude that the points extracted from the moment matrix are inside the semialgebraic set. This is the first example where such a pathological behaviour is explicit.

Example 4.2. We consider the problem of minimizing \( f = (1 + X)(X-1)^2 \) on \( S(1 - X^2, -X^3) = [-1, 0] \). Notice that the SoS hierarchy is exact, since \( f^* = 0 \) and:

\[(1 + X)(X-1)^2 = \frac{1}{2}((1 + X)^2 + 1 - X^2)(X-1)^2 \in Q_4(1 - X^2, -X^3).\]

This implies that \( f_{\text{SoS,2}} = f_{\text{MoM,2}} = f^* \). The only minimizer of \( f \) on \( S \) is \( -1 \), and \( I(-1) = (X + 1) \): therefore we would expect to get flat truncation at degree zero for a generic element, and in particular \( \text{rank} H_{\lambda^*}^0 = \text{rank} H_{\lambda^*}^1 = 1 \). But this is not the case if we consider the MoM relaxation of order 2. Indeed an explicit computation shows that \( \lambda = \frac{1}{2}(e_{-1}^{[4]} + e_1^{[4]}) \in L_{4}^{\min}(f; g) \), and \( \text{rank} H_{\lambda}^1 = \text{rank} H_{\lambda}^2 = 2 \). Therefore a generic \( \lambda^* \in L_{4}^{\min}(f; g) \) cannot satisfy flat truncation at degree \( t = 0 \). More precisely, it is possible to show that \( L_{4}^{\min}(f; g) = \text{conv}\left(e_{-1}^{[4]}, \frac{1}{2}(e_{-1}^{[4]} + e_1^{[4]})\right) \). Therefore a generic \( \lambda^* \in L_{4}^{\min}(f; g) \) will also satisfy \( \text{rank} H_{\lambda^*}^1 = \text{rank} H_{\lambda^*}^2 = 2 \).
We confirm numerically the computation above, using the package MomentPolynomialOpt.jl to compute \( f^* \) and a generic \( \lambda^* \in \mathcal{L}_{\xi}^{\text{min}}(f; g) \): the pseudo-moments that we obtain are We compute the singular values of \( H_{\lambda^*}^1, H_{\lambda^*}^2 \) and \( H_{\lambda^*}^3 \) to have a numerically stable indication of the ranks:

| Sing. Val. of \( H_{\lambda^*}^1 \) | 0.999999989784975 |
| Sing. Val. of \( H_{\lambda^*}^2 \) | 1.352956188465637, 0.6468912220427679 |
| Sing. Val. of \( H_{\lambda^*}^3 \) | 2.2063794508570065, 0.7931627759613444, 7.983780245045715 \times 10^{-8} |

This confirms the theoretical description and shows that the rank condition is numerically satisfied for \( t = 1 \). The points extracted from the matrix are \( \xi_1 \approx 0.9997640487211856 \) and \( \xi_2 \approx -1.0000000483192044 \): notice that \( \xi_1 \notin S \). This happens because the condition \( \text{rank } H_{\lambda^*}^1 = \text{rank } H_{\lambda^*}^{t+d_k} \) is not satisfied (we cannot compute \( H_{\lambda^*}^{t+d_k} = H_{\lambda^*}^3 \) as \( 3 = t + d_k > d = 2 \)).

On the other hand, if we increase the order of the relaxation and compute \( \lambda^* \in \mathcal{L}_{\xi}^{\text{min}}(f; g) \) generic, we can verify flat truncation for \( t = 0 \) and the only point extracted is \(-1\). Moreover, notice, from Lemma 3.17 applied with \( s = 1 \) and the remark below, that in this case it is enough to check \( \text{rank } H_{\lambda^*}^0 = \text{rank } H_{\lambda^*}^1 \), to verify that \( \text{rank } H_{\lambda^*}^1 = \text{rank } H_{\lambda^*}^{t+d_k} \), since the condition \( 0 = t \leq d + s - \text{deg}(g) = 1 \) is satisfied.

We have seen that flat truncation implies MoM exactness and a finite set of minimizers. We now show that, under the assumption of MoM finite convergence, flat truncation is equivalent to the zero-dimensionality of the support for the quadratic module \( Q + (f - f^*) \) defining the minimizers.

We first need a technical lemma, that will be important to investigate the relationship between \( \mathcal{L}_{2d}^{\text{min}}(f; g) \) and \( \mathcal{L}_{2d}^{(1)}(g, \pm(f - f^*)) \). Indeed, notice that \( \mathcal{L}_{2d}^{(1)}(g, \pm(f - f^*)) \subset \mathcal{L}_{2d}^{\text{min}}(f; g) \), by definition, but the converse inclusion is not true in general, since for \( \lambda \in \mathcal{L}_{2d}^{\text{min}}(f; g) \), we only have \( \langle \lambda, f \rangle = f^* \), and not \( f - f^* \in \text{Ann}_{d - \text{deg}(f)}(\lambda) \).

**Lemma 4.3.** Let \( f \in Q_{2k}(g), \lambda \in \mathcal{L}_{2d}(g) \) and \( t \in \mathbb{N} \) with \( 0 \leq t \leq d - k \). Then \( \langle \lambda, f \rangle = 0 \) implies for all \( q \in \mathbb{R}[X]_t \), \( \langle \lambda, qf \rangle = 0 \). In other words, \( f \in \text{Ann}_t(\lambda) \).

**Proof.** We set \( g_0 = 1 \) for notational convenience. Let \( f = \sum_i s_i g_i = \sum_{i,j} p_{i,j}^2 g_i \in Q_{2k}(g) \), with \( \text{deg} p_{i,j}^2 \leq 2k \). We want to prove that for all \( q \in \mathbb{R}[X] \) such that \( \text{deg}(q) \leq t \) we have \( \langle \lambda, qf \rangle = 0 \). In particular, it is enough to prove that:

\[
\langle \lambda, q p_{i,j}^2 g_i \rangle = 0 \quad \text{for all } i, j \text{ and } q \in \mathbb{R}[X]_t. \tag{6}
\]

Now, notice that \( \langle \lambda, f \rangle = 0 \) implies \( \langle \lambda, p_{i,j}^2 g_i \rangle = 0 \) for all \( i, j \) (since \( \lambda \) is nonnegative on \( Q_{2k}(g) \)), and therefore for all \( T \in \mathbb{R} \) and \( h \in \mathbb{R}[X]_{t + \text{deg} p_{i,j}} \) we have:

\[
0 \leq \langle \lambda, (p_{i,j} - Th)^2 g_i \rangle = T^2 \langle \lambda, h^2 g_i \rangle - 2T \langle \lambda, h p_{i,j} g_i \rangle
\]

(we can apply \( \lambda \) to \( (p_{i,j} - Th)^2 g_i \) since \( \text{deg}((p_{i,j} - Th)^2 g_i) \leq 2t + 2k \leq 2d \)). For all \( h \in \mathbb{R}[X]_{t + \text{deg} p_{i,j}} \) the polynomial \( T^2 \langle \lambda, h^2 g_i \rangle - 2T \langle \lambda, h p_{i,j} g_i \rangle \) is nonnegative by the above inequality, and since it vanishes at \( T = 0 \), it has a double root at \( T = 0 \). This implies that \( \langle \lambda, h p_{i,j} g_i \rangle = 0 \) for all \( h \in \mathbb{R}[X]_{t + \text{deg} p_{i,j}} \). If we substitute \( h = q p_{i,j} \), we deduce eq. (6) for all \( q \in \mathbb{R}[X]_t \), and thus \( f \in \text{Ann}_t(\lambda) \). \( \square \)

We can now prove the equivalence between the flat truncation and the zero-dimensionality of the support for the quadratic module \( Q + (f - f^*) \) defining the minimizers. The proof relies on two main ideas:

(i) we use Lemma 4.3 to move from \( \mathcal{L}_{2d}^{\text{min}}(f; g) \) to \( \mathcal{L}_{2d}^{(1)}(g, \pm(f - f^*)) \);
(ii) we use Theorem 3.19 to analyze the zero dimensional case.

**Theorem 4.4.** Assume that we have MoM finite convergence. Then \( \dim \frac{\mathbb{R}[X]}{\text{supp}(Q(g)+f-f')} = 0 \) if and only if there exists \( d \) such that a generic \( \lambda^* \in \mathcal{L}_d^{\text{min}}(f,g) \) has flat truncation.

In this case, if \( \theta = \Theta(S^{\text{min}}) \) is the interpolation degree and \( D = \max(d_g, \lceil \frac{\deg(f)}{2} \rceil) \), there exists \( \delta \in \mathbb{N} \) such that \( f - f^* \in \mathcal{Q}_{2\delta}(g) \) and flat truncation at degree \( \Theta \) happens for all \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \), when \( d \) is such that:

1. \( (\sqrt[2\delta]{\text{supp}(Q(g))})^{2\delta+2\theta+2D-\deg(f)} \subseteq Q_{2\delta}(g) \);
2. \( \mathcal{I}(S^{\text{min}})_{2\delta+2D} \subseteq Q_{2\delta}(g) + (f-f')_{2\delta} \);
3. \( \delta + 2\theta + 2D - \deg(f) \leq d \).

**Proof.** Let us assume without loss of generality that \( f^* = 0 \).

We first show that flat truncation implies \( \dim \frac{\mathbb{R}[X]}{\text{supp}(Q(f))} = 0 \). As in the proof of Theorem 4.1 if \( \lambda^* \in \mathcal{L}_d^{\text{min}}(f,g) \) is generic satisfying flat truncation at degree \( t \) then \( (\lambda^*)^{[2(t+\delta)]} \) is a generic element of \( \mathcal{L}_d^{\text{min}}(g+f)^{[2(t+\delta)]} \). Since the flat truncation property is satisfied, we conclude from Theorem 3.18, in particular point (iv), that \( (\sqrt[2\delta]{\text{supp}(Q+f)}) = (\text{Ann}_{t+1}(\lambda^*)) = \mathcal{I}(S^{\text{min}}) \) and \( \dim \frac{\mathbb{R}[X]}{\text{supp}(Q(f))} = \dim \frac{\mathbb{R}[X]}{\text{supp}(Q(f))} = 0 \).

Conversely, if \( \dim \frac{\mathbb{R}[X]}{\text{supp}(Q(f))} = 0 \), we deduce from Theorem 3.19 that the flat truncation property is satisfied for any \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \) at degree \( \theta = \Theta(S^{\text{min}}) = \Theta(S(g,f)) \) for \( d \) such that \( \mathcal{I}(S^{\text{min}})_{2\theta+2D} \subseteq Q_{2\delta}(g) + (f-f')_{2\delta} \). Let \( a = 2\theta + 2D \) and \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \) generic. We want to show that \( \lambda^{[a]} \in \mathcal{L}_d^{\text{min}}(g,f)^{[a]} \), so that we can conclude using Theorem 3.19. Since \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \) is such that \( \mathcal{I}(S^{\text{min}})_{2\theta+2D} \subseteq Q_{2\delta}(g) + (f-f')_{2\delta} \), it is sufficient to prove that:

\[
\langle \lambda, qf \rangle = 0 \quad \text{for all } q \text{ of degree } \leq a - \deg(f).
\]

(7)

We prove now (7), starting from \( \langle \lambda, f \rangle = f^* = 0 \). MoM finite convergence implies that \( \langle \lambda, f \rangle \geq 0 \) for all \( \lambda \in \mathcal{L}_d^{\text{min}}(g) \), and therefore \( f \in \mathcal{L}_d^{\text{min}}(g \pm f) = Q_{2\delta}(g) \). Let \( \delta \leq d \) be minimal such that \( f \in Q_{2\delta}(g) \) and let \( h = h_1, \ldots, h_m \) be a grading basis of \( \sqrt[2\delta]{\text{supp}(Q)} \). From [Mar08] Lem. 4.1.4 we deduce that \( Q_{2\delta}(g) + h_{2\delta} \) is closed (as a subset of \( \mathbb{R}[X]_{2\delta} \) with the Euclidean topology, see also the proof of Proposition 3.10), and therefore \( Q_{2\delta}(g) \subseteq Q_{2\delta}(g) + (h)_{2\delta} \). Thus we can write:

\[
f = g + h = \sum_{i=0}^s s_i g_i + \sum_{i=1}^m p_i h_i \in Q_{2\delta}(g) + (h)_{2\delta},
\]

where we set \( g_0 = 1 \) for notation convenience, \( g = \sum_{i=0}^s s_i g_i \in Q_{2\delta}(g) \) and \( h = \sum_{i=1}^m p_i h_i \in (h)_{2\delta} \). It is then enough to prove that \( \langle \lambda, qg \rangle = (\lambda, qh) = 0 \), where \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \) and \( \deg(qg) \leq b, \deg(qh) \leq b \) for \( b = 2\delta + a - \deg(f) = 2\delta + 2\theta + 2D - \deg(f) \).

We start by proving \( \langle \lambda, qh \rangle = 0 \). We deduce from Lemma 3.6 that for \( d \) big enough we have \( (h)_{b} \subseteq Q_{2\delta}(g) \) and \( \mathcal{L}_d^{\text{min}}(g)^{[b]} \subseteq \mathcal{L}_d^{\text{min}}(g)^{[b]} \). Therefore

\[
\langle \lambda, qh \rangle = \langle \lambda[1^b], qh \rangle = 0.
\]

Now we prove that \( \langle \lambda, qg \rangle = 0 \). Since \( \delta + (a - \deg(f)) \leq d \), we can apply Lemma 4.3 with \( g \in Q_{2\delta}(g) \) and \( t = a - \deg(f) \geq \deg(qg) \), and conclude that \( \langle \lambda, qg \rangle = 0 \), as desired.

Therefore \( \langle \lambda, qf \rangle = (\lambda, qg) + (\lambda, qh) = 0 \) for all \( q \) of degree \( \leq a - \deg(f) \) and (7) is satisfied. This implies that \( \lambda^{[a]} \in \mathcal{L}_d^{\text{min}}(g \pm f)^{[a]} \), or in other words \( \mathcal{L}_d^{\text{min}}(f,g)^{[a]} \subseteq \mathcal{L}_d^{\text{min}}(g \pm f)^{[a]} \). Therefore we can apply Theorem 3.19 to conclude that the flat truncation property is satisfied for all \( \lambda \in \mathcal{L}_d^{\text{min}}(f,g) \) at degree \( \Theta \).

Let us briefly comment the degree conditions in Theorem 4.4.
(i) If $S$ has nonempty interior, it is not necessary to check the first condition, since in this case
$\text{supp } Q = 0$. More generally if the quadratic module is reduced, that is if $\sqrt{\text{supp } Q} = \text{supp } Q,$
the first condition is automatically satisfied;

(ii) The second condition is the key one: it tells us that flat truncation happens when the ideal of
the minimizers, truncated in the appropriate degree, can be described using the truncated
quadratic module and the truncated ideal generated by $f - f^*$;

(iii) The third condition is technical, derived from Lemma 4.3. It allows to move from $\mathcal{L}^\text{min}_{2d}(f; g)$
to $\mathcal{L}^\text{min}_{2d}(g, \pm (f - f^*))$, where we can apply the results of the previous section.

Related properties have been previously investigated. It is shown in [Nie13b, Th. 2.2] that,
under genericity assumptions, if for an order $d$ big enough we have $f^*_\text{SoS},d = f^*_\text{MoM},d$ (strong duality)
and $\text{sup} = \text{max}$ in the definition of $f^*_\text{MoM},d$, then there is finite convergence (that is $f^*_\text{MoM},d = f^*$) if
and only if flat truncation is satisfied for every $\lambda \in \mathcal{L}^\text{min}_{2d}(f; g)$. Theorem 4.4 applies for other cases,
for instance when there is finite convergence but the SoS hierarchy is not exact (see Example A.8).
This is made possible by analysing the closure of the quadratic modules we are considering. As a
corollary of Theorem 4.4, we will show (in Theorem 4.7 and Corollary 4.8) that, under genericity
assumption, we have finite convergence, that the MoM hierarchy is exact and that the flat truncation
property is satisfied.

Another improvement made is the estimation of the order $d$ of the hierarchy that is sufficient to
have flat truncation, answering a question in [Nie13b, Sec. 5]. This is the first result in this direction.
These conditions depends on properties of the minimizers and the quadratic module $Q_{2d}(g)$ that
might be difficult to check a priori. In particular, they depend on the interpolation degree of the
minimizers. However, they may be analyzed in some specific cases, such as optimization problems
with a single minimizer, to deduce more precise bounds. Moreover, the relation between the degree
of flat truncation and the interpolation degree $\theta$ shows that computing the degree of flat truncation
is at least as hard as computing $\theta$, which is difficult with no a priori knowledge on the minimizers.

We illustrate Theorem 4.4 in the following example, showing how it can help to predict the flat
truncation degree.

Example 4.5. We continue Example 2.5. Notice that $f - f^* = X^2 \in Q_2 := Q_2(g) = Q_2(1 - X^2 - Y^2, X + Y - 1)$ (i.e. the SoS hierarchy is exact) and then the MoM hierarchy has finite convergence. Using
Theorem 4.4, we analyse if flat truncation holds at some degree. We have $I(S^{\text{min}}) = (X, Y - 1) \subset \sqrt{\text{supp}(Q + (f - f^*))} = \sqrt{\text{supp}(Q + (X^2))}$ where $Q := Q(1 - X^2 - Y^2, X + Y - 1)$. Indeed:

$$X = \frac{X^2 + (Y - 1)^2}{2} + \frac{1 - X^2 - Y^2}{2} + X + Y - 1 \in Q_2 \subset Q_2 + (X^2)_2$$

$$-X + \varepsilon = \frac{\varepsilon}{2}(1 - \frac{X^2}{\varepsilon^2} + (1 - \frac{X}{\varepsilon})^2) \in Q_2 + (X^2)_2 \forall \varepsilon > 0 \Rightarrow -X \in Q_2 + (X^2)_2$$

$$1 - Y = \frac{1}{2}(X^2 + (1 - Y)^2 + 1 - X^2 - Y^2) \in Q_2 \subset Q_2 + (X^2)_2$$

$$Y - 1 = X + Y - 1 - X \in Q_2 + Q_2 + (X^2)_2 = Q_2 + (X^2)_2$$

that implies $(X, Y - 1) \subset \text{supp}(Q_2 + (X^2)_2) \subset \sqrt{\text{supp}(Q + (f - f^*))}$. And thus $\dim \frac{\text{min}(X)}{\text{supp}(Q + (f - f^*))} = 0$.

Theorem 4.4 implies that flat truncation holds for a high enough order $d$ of the MoM relaxation.

We investigate the degree conditions in Theorem 4.4 to prove that flat truncation happens for
the MoM hierarchy at order $d = 1$. We have $I(S^{\text{min}}) = (X, Y - 1)$, $\theta = 0$, $d = 1$, $\deg(f) = 2$, $D = 1$ and
$\delta = 1$.

(i) As $S$ has nonempty interior, $\text{supp } Q = 0$ and the first point (i) is satisfied.

(ii) Notice that $2(\theta + D) = 2$, and therefore we have to show that $(X, Y - 1) \subset Q_2 + (X^2)_2$. Since
we have shown above that $(X, Y - 1) \subset Q_2 + (X^2)_2$, it is enough to prove that $\pm X^2, \pm X(Y -
Theorem 4.4 are satisfied for the relaxation order which implies that the SoS hierarchy is exact and thus the MoM hierarchy has finite convergence.

which hold generically, implies the SoS finite convergence property.

Under these conditions, global (BHC), are satisfied, then the flat truncation property holds. These are conditions on the minimizers

Proof. If BHC hold at every minimizer of \( f \) then \( f - f^* \in Q(\mathcal{g}) \) (see [Mar06]), which implies that the SoS hierarchy is exact and thus the MoM hierarchy has finite convergence. Moreover, if the BHC conditions hold at every minimizer of \( f \) then \( \dim \frac{\mathbb{R}[X]}{\supp(Q + (f - f^*))} = 0 \) (see the proof of [Mar06] Th. 2.3), where it is shown that the field of fractions of \( \mathbb{R}[X] \) modulo any minimal prime ideal lying over \( \supp(Q + (f - f^*)) \) is isomorphic to \( \mathbb{R} \), that implies \( \dim \frac{\mathbb{R}[X]}{\supp(Q + (f - f^*))} = 0 \). Then Theorem 4.4 implies that flat truncation occurs for all \( \lambda \in \mathcal{L}_{2d}^{\min}(f; g) \) and in particular for generic elements, when conditions (i)-(iii) are satisfied. Finally Theorem 4.4 allows to conclude that the MoM hierarchy is exact.

4 this means that the \( t_i \)'s vanish at \( \xi \) and that their gradients (or differentials) are linearly independent at \( \xi \)

4.2 Boundary Hessian Conditions

In this section, we show that if regularity conditions, known as Boundary Hessian Conditions (BHC), are satisfied, then the flat truncation property holds. These are conditions on the minimizers of a polynomial \( f \) on a basic semialgebraic set \( S \) introduced by Marshall in [Mar06] and [Mar09], which are particular cases of the so called local-global principle. Under these conditions, global properties of polynomials (e.g. checking the BHC at the minimizers of \( f \) on \( S(Q) \)). We refer to [Sch05a], [Sch06] and [Mar08, Ch. 9] for more details.

Definition 4.6 (Boundary Hessian Conditions). Consider a POP with inequality constraints \( g = g_1, ..., g_r \), equality constraints \( h = h_1, ..., h_s \) and objective function \( f \). Let \( V = \mathcal{V}_g(h) \subset \mathbb{R}^n \) and suppose that \( Q = Q(\mathcal{g}, \pm h) \) is Archimedean. We say that the Boundary Hessian Condition hold at a minimizer point \( \xi \in S(\mathcal{g}, \pm h) \) of \( f \) if \( \xi \) is a smooth point of \( V \) and:

(i) we can choose \( g_i = t_1, ..., g_i = t_k \) that are part of a regular system of parameters \( t_1, ..., t_m, m \geq k \), for \( V \) at \( \xi \) and for some neighbourhood \( U \) of \( \xi \) we have \( S(g_1, ..., g_i, \pm h) \cap U = S(g, \pm h) \cap U \);

(ii) On \( V \), locally at \( \xi \) we have that \( \nabla f = a_1 \nabla t_1 + \cdots + a_m \nabla t_m \), where \( a_i \) are strictly positive real numbers;

(iii) On \( V \), locally at \( \xi \) we have that \( \nabla f = a_1 \nabla t_1 + \cdots + a_m \nabla t_m \) is positive definite in \( t_{k+1}, ..., t_m \).

These conditions are related to standard conditions in optimization at a point \( \xi \in S \) (see [Ber99] and [Nie14]). Notice that when BHC hold, the minimizers are non-singular, isolated points and thus finite. It is proved in [Mar06] that if BHC holds at every minimizer of \( f \) on \( S(\mathcal{g}) \) then \( f - f^* \in Q(\mathcal{g}) \), which implies that the SoS hierarchy is exact. [Nie14] proved that the MoM at every minimizer of \( f \), which hold generically, implies the SoS finite convergence property.

In this section, we prove that, if the BHC hold, then the flat truncation property holds. For simplicity, we restrict to the case of only inequalities, i.e. we assume \( h = 0 \).

Theorem 4.7. Let \( f \in \mathbb{R}[X] \), \( Q = Q(\mathcal{g}) \) be an Archimedean finitely generated quadratic module and assume that the BHC hold at every minimizer of \( f \) on \( S = S(\mathcal{g}) \). Then the SoS hierarchy is exact, and the flat truncation holds for all \( \lambda \in \mathcal{L}_{2d}^{\min}(f; g) \) when \( d \) is big enough. If conditions (i)-(iii) in Theorem 4.4 are satisfied for the relaxation order \( d \), then the flat truncation property holds.

Proof. If BHC hold at every minimizer of \( f \) on \( S(\mathcal{g}) \) then \( S^{\min} \) is finite and \( f - f^* \in Q(\mathcal{g}) \) (see [Mar06]), which implies that the SoS hierarchy is exact and thus the MoM hierarchy has finite convergence. Moreover, if the BHC conditions hold at every minimizer of \( f \) on \( S \), then \( \dim \frac{\mathbb{R}[X]}{\supp(Q + (f - f^*))} = 0 \) (see the proof of [Mar06] Th. 2.3), where it is shown that the field of fractions of \( \mathbb{R}[X] \) modulo any minimal prime ideal lying over \( \supp(Q + (f - f^*)) \) is isomorphic to \( \mathbb{R} \), that implies \( \dim \frac{\mathbb{R}[X]}{\supp(Q + (f - f^*))} = 0 \). Then Theorem 4.4 implies that flat truncation occurs for all \( \lambda \in \mathcal{L}_{2d}^{\min}(f; g) \) and in particular for generic elements, when conditions (i)-(iii) are satisfied. Finally Theorem 4.4 allows to conclude that the MoM hierarchy is exact.
We show now that flat truncation and moment exactness hold generically in the space \( \mathcal{A} \) of polynomials \( (f, g) \) of bounded degree for which \( Q(g) \) is Archimedean. We notice that if one of the \( g_i \)'s has even degree equal to \( 2d_i \), then \( \mathcal{A} \) has nonempty interior: indeed, if we choose \( g_1 = R^2 - x_1^{2d_1} - \ldots - x_n^{2d_1} \), for any sufficiently small perturbation \( \overline{g}_1 \) of \( g_1 \) in degree \( d_1 \), \( S(\overline{g}_1) \) is compact. Therefore \( Q(\overline{g}) \) satisfies the Archimedean condition for all sufficiently small perturbations \( \overline{g} \) of \( g \) (see also [Mar08, Th. 7.1.1]). This is the typical situation in polynomial optimization, where it is common to set \( g_1 := R^2 - x_1^2 - \ldots - x_n^2 \).

For polynomials \( f \in \mathbb{R}[X]_d \) and \( g_1 \in \mathbb{R}[X]_{d_1}, \ldots, g_s \in \mathbb{R}[X]_{d_s} \), we say that a property holds generically (or that the property holds for generic \( f, g_1, \ldots, g_s \)) if there exists finitely many nonzero polynomials \( \phi_1, \ldots, \phi_l \) in the coefficients of polynomials in \( \mathbb{R}[X]_d \) and \( \mathbb{R}[X]_{d_1}, \ldots, \mathbb{R}[X]_{d_s} \) such that, when \( \phi_1(f, g) \neq 0, \ldots, \phi_l(f, g) \neq 0 \), the property holds. We say that the property holds for \( (f, g) \) generic satisfying the Archimedean condition if the property hold for all \( (f, g) \in \mathcal{A} \cap \{ \phi_1(f, g) \neq 0, \ldots, \phi_l(f, g) \neq 0 \} \).

**Corollary 4.8.** For \( f \in \mathbb{R}[X]_d \) and \( g_1 \in \mathbb{R}[X]_{d_1}, \ldots, g_s \in \mathbb{R}[X]_{d_s} \) generic satisfying the Archimedean condition, the SoS hierarchy is exact, the MoM hierarchy is exact and the flat truncation holds for all \( \lambda \in \mathcal{L}^{\min}_d(f; g) \) when \( d \) is big enough: if conditions (i)-(iii) in Theorem 4.4 are satisfied for the relaxation order \( d \), then the flat truncation holds.

**Proof.** By [Nie14, Th. 1.2] BHC hold generically. We apply Theorem 4.7 to conclude. \( \square \)

Genericity of flat truncation can also be determined by combining other previous results, as follows. In [Nie13b], it is shown that finite convergence and flat truncation are equivalent conditions under some (non-trivial) genericity assumptions (Assumption 2.1 in [Nie13b], no duality gap and sup = \text{max} in the SoS hierarchy, see Theorem 2.2, p. 492). In [Nie14], it is shown that BHC are generic properties, using local optimality conditions. We can combine these two results to show that under (stronger) generic conditions, flat truncation of the Lasserre’s hierarchy holds, but some attention is needed. First, one needs to ensure that generically there is no duality gap, for instance using the fact that the semialgebraic set has nonempty interior or using the results of [HH16], and that the supremum is attained. On the other hand, Corollary 4.8 only requires the BHC to hold to ensure generic flat truncation.

Here is an example where BHC holds.

**Example 4.9** (Robinson form). We find the minimizers of Robinson form \( f = x^6 + y^6 + z^6 + 3x^2y^2z^2 - x^4(y^2 + z^2) - y^4(x^2 + z^2) - z^4(x^2 + y^2) \) on the unit sphere \( h = x^2 + y^2 + z^2 = 1 \). The Robinson polynomial has minimum \( f^* = 0 \) on the unit sphere, and the minimizers on \( \nu_R(h) \) are:

\[
\frac{\sqrt{3}}{3} (1, \pm 1, \pm 1), \frac{\sqrt{2}}{2} (0, \pm 1, \pm 1), \frac{\sqrt{2}}{2} (\pm 1, 0, \pm 1), \frac{\sqrt{2}}{2} (\pm 1, \pm 1, 0).
\]

BHC are satisfied at every minimizer (see [Nie14, Ex. 3.2]), flat truncation holds and we can recover the minimizers from Theorem 4.7. We estimate the bounds of Theorem 4.4 and compare with the numerical experiments. It is not necessary to check (i), since \( (h) = \nu(h) \) for the point (ii), we compute the interpolation degree of the minimizers. The vanishing ideal of the minimizers is \((3xyz - xyz, 6z^3 - 5z^3 + z, -6y^2z^2 + 3y^2z^2 - y, x^2 + y^2 + z^2 - 1, 6x^2y^2 + 2xy^2 - xz^2 - x, 4y^2z^2 + 2y - 3z^2 + 2)\) which has generators of degree 5, and this ideal cannot be generated in degree 4. Therefore the interpolation degree is \( \theta = 4 \). Then \( 2\theta + 2D = 14 \), and thus we expect flat truncation for \( d \geq 7 \). For the point (iii), we notice that, since \( \text{deg} f = 6 \), then \( \delta \geq 3 \) in Theorem 4.4. For the flat truncation, we then need to have \( d \geq \delta + 2\theta + 2D - \text{deg}(f) \geq 3 + 10 + 6 - 6 = 11 \). However, in practice for this example we have flat truncation numerically at order 6 and not before (using the SDP solver SDPA). We recover a good approximation of the minimizers at this order:

\[
\begin{align*}
\nu, M &= \text{minimize}(f, [h], [], X, 6) \\
w, Xi &= \text{get\_measure}(M)
\end{align*}
\]

Here \( f^*_{\text{MoM,6}} = -1.27211 \cdot 10^{-7} \) and the minimizers with positive coordinates are (all the twenty minimizers are found):
We conclude applying Theorem 4.4 and Theorem 4.1.

Let \( f \) be the approximation of the minimum \( V \). The variety \( \text{dim} R \) is finite and that every positive linear functional satisfies flat truncation from Theorem 3.18. Then Theorem 3.18 implies that every truncated positive linear functional is represented by a measure, which also implies MoM finite convergence. We conclude applying Theorem 4.4 and Theorem 4.1.

As corollaries, we have that the conclusions of Theorem 4.10 hold:

- for the moment hierarchy \( (\mathcal{L}_{2d}(\Pi g))_{d \in \mathbb{N}} \) (recall that we denote \( \Pi g \) all the products of the \( g_i \)'s), if \( S = S(g) = S(\Pi g) \) is finite, since by the real Nullstellensatz,
  \[
  \dim \frac{\mathbb{R}[x]}{\text{supp}(\Pi g)} = \dim \frac{\mathbb{R}[x]}{\text{supp} \ g} = \dim \frac{\mathbb{R}[x]}{\sqrt{\text{supp} \ g}} = \dim \frac{\mathbb{R}[x]}{I(\Pi g)} = 0.
  \]

  See [Nie13c, Th. 4.1] and [LLR08, Rem. 4.9]. Example A.1 shows that we cannot replace the zero-dimensionality hypothesis in Theorem 4.10 by the finiteness of \( S \) for a general quadratic modules.

- for the moment hierarchy \( (\mathcal{L}_d(\Pi g, \pm h))_{d \in \mathbb{N}} \) when \( \mathcal{V}_{\mathbb{R}}(h) \) is finite, since for \( Q = Q(g, \pm h) \),
  \[
  \dim \frac{\mathbb{R}[x]}{\text{supp} Q} = \dim \frac{\mathbb{R}[x]}{\sqrt{\text{supp} Q}} = \dim \frac{\mathbb{R}[x]}{\mathbb{R}[x]} \leq \dim \frac{\mathbb{R}[x]}{\mathbb{R}[x]} = 0.
  \]

  See [Nie13c, Th. 1.1] and [LLR08]. This includes Polynomial Optimization problems with binary variables and equations of the form \( X = 0 \), for which MoM relaxations are of particular interest, see e.g. [Lau03].

Example 3.20 shows that Theorem 4.10 is more general than the two cases above.

Notice that, even if the SoS hierarchy has the finite convergence property and the MoM hierarchy is exact, it may not be SoS exact for a finite real variety, as shown in Example A.7 and Example A.8.

Example 4.11 (Gradient ideal, [NDS06]). We compute the minimizers of Example A.7. Let \( f = (X^4Y^2 + X^2Y^4 + Z^6 - 2X^2Y^2Z^5)X^8 + Y^8 + Z^8 \in \mathbb{R}[X,Y,Z] \). We want to minimize \( f \) over the gradient variety \( \mathcal{V}_{\mathbb{R}}(\frac{\partial f}{\partial X}, \frac{\partial f}{\partial Y}, \frac{\partial f}{\partial Z}) \) with \( \dim \frac{\mathbb{R}[x]}{(\frac{\partial f}{\partial X}, \frac{\partial f}{\partial Y}, \frac{\partial f}{\partial Z})} = 0 \). By Theorem 4.10, we deduce that flat truncation holds for an order of relaxation \( d \) high enough. In this example, we have \( \theta = 0, d = 4, \deg(f) = 8, \delta \geq 4 \), so that we expect flat truncation at an order \( d \geq 4 \), from Theorem 4.4.

\[
\begin{align*}
v, M &= \text{minimize}(f, \text{differentiate}(f, X), [], X, 4) \\
w, Xi &= \text{get_measure}(M, 2\cdot 10^{-2})
\end{align*}
\]

The approximation of the minimum \( f^{*} = 0 \) is \( v = -1.6279 \cdot 10^{-9} \), and the decomposition with a threshold of \( 2 \cdot 10^{-2} \), used to determine the correct numerical rank of the moment matrix, gives the following numerical approximation of the minimizer (the origin):

\[
\xi = (2.976731510689691 \cdot 10^{-17}; -9.515032317137384 \cdot 10^{-19}; 3.763401209219283 \cdot 10^{-18}).
\]
We investigated the convex cones we can define the augmented Jacobian ideal. Assumption 2.2 in [Nie13a] is not satisfied, since the minimizer is a singular point. Moreover notice that in our theorem we use only the defining inequalities \( g \) and not their products \( \Pi g \), as done in [Nie13a, Th. 2.3] (in other words, we consider the quadratic module and not the preorder).

**Example 4.12** (Singularity minimizer). We minimize \( f = X \) on the compact semialgebraic set \( S = S(X^3 - Y^2, 1 - X^2 - Y^2) \). We have \( f^* = 0 \) and the only minimizer is the origin, which is a singular point of the boundary of \( S \). Thus BHC does not hold, and we cannot apply Theorem 4.7. We have \( \dim \frac{R[X]}{\text{supp}(Q+X)} = 0 \) since \( \text{supp}(Q+X) \supset (X, Y^2) \), but we cannot apply Theorem 4.4 as we don’t have finite convergence of the SoS and MoM hierarchies. Indeed \( X \in Q = Q(X^3 - Y^2, 1 - X^2 - Y^2) \), since \( X \notin Q(X^3, 1 - X^2) \). This implies that the SoS and MoM hierarchies do not have finite convergence, following Example A.3. This example also shows that we cannot remove the hypothesis of MoM finite convergence in Theorem 4.4.

To get flat truncation, we add the augmented Jacobian equations, that define a finite real variety, as we show in the following. First notice that, since \( \mathcal{V}(X^3 - Y^2) \) is singular, Assumption 2.2 in [Nie13a] is not satisfied and the finite convergence of the hierarchy \( T_{2d}(g, \pm h) \) using the augmented Jacobian equations cannot be deduced from [Nie13a, Th. 2.3]. Generators for augmented Jacobian variety are \( h' = (1 - X^2 - Y^2)(X^3 - Y^2), Y(1 - X^2 - Y^2), Y(X^3 - Y^2) \). The real roots are \((-1, 0), (1, 0), (0, 0)\) and the two real intersections of \( 1 - X^2 - Y^2 = 0 \) and \( X^3 - Y^2 = 0 \). Therefore \( \dim \frac{R[X]}{\text{supp}(Q+\langle h' \rangle)} \leq \dim \frac{R[X]}{\text{supp}(Q+\langle h' \rangle)} = 0 \), and Theorem 3.19 implies flat truncation. We recover the minimizer considering the MoM relaxation of order 5:

\[
\begin{align*}
v, M &= \text{polar\_minimize}(f, [], [x^3-y^2, 1-x^2-y^2], X, 5) \\
w, Xi &= \text{get\_measure}(M, 2.e-3)
\end{align*}
\]

The approximation of the minimum \( f^* = 0 \) is \( v = -0.0045 \), and the decomposition of the moment sequence with a threshold of \( 2 \cdot 10^{-3} \) gives the following approximation of the minimizer (the origin):

\[
\xi = (-0.004514367348787526, 2.1341684460860045 \cdot 10^{-21}).
\]

The error of approximation on \( \xi \) is of the same order than the error on the minimum \( f^* \).

## 5 Conclusion

We investigated the convex cones \( L_d(g) \) dual to the truncated quadratic modules \( Q_d(g) \) from a new perspective. We studied the kernels of moment matrices or annihilators of moment sequences
in these cones and characterize the ideal they generate (Theorem 3.14). We focused on the zero-dimensional case and its relationships with the flat truncation property (Theorem 3.18 and Theorem 3.19), that can be used to certify that a linear functional is represented by a measure.

The main contributions of the paper are the applications of the previous analysis to flat truncation in Lasserre’s MoM hierarchies for Polynomial Optimization. We studied the flat truncation property in this context (Theorem 4.1) and deduced new necessary and sufficient conditions for flat truncation (Theorem 4.4). These conditions can be used to show that, under regularity and thus genericity assumptions (Boundary Hessian Conditions), the flat truncation property is satisfied (Theorem 4.7, Corollary 4.8). We applied these results to Polynomial Optimization on finite sets (Theorem 4.10), generalizing and giving a unified presentation to different results in the literature.

Theorem 4.4 provides the first known degree bounds for the flat truncation property to hold, in terms of the inequalities \( g \) and the objective function \( f \) (in particular depending on the interpolation degree of the minimizers). An interesting question would be to investigate if it is possible to improve these degree bounds. Another possible research direction is to investigate regularity conditions, simpler than Boundary Hessian Conditions, that imply flat truncation for MoM hierarchy of a certain order \( d \).

**Acknowledgments.** The authors thank D. Henrion and M. Laurent for useful discussions about the outer approximation of semialgebraic sets with moments of degree one and flat truncation properties, and the anonymous referees for their helpful suggestions for the improvement of the presentation of the paper.

**A Appendix: Examples of exact and non-exact Lasserre’s hierarchies**

In this appendix, we give examples showing how the notions of finite convergence and exactness of the SoS and MoM hierarchies are (and are not) related.

**No finite convergence.** We start presenting the first example of optimization over a finite semialgebraic set, where we do not have finite convergence of the MoM and SoS hierarchies.

**Example A.1** (see also [Sch05a] Ex. 3.2], [Sch05b] Rem. 3.15], Example 3.5, Example A.6]. Consider the minimization of \( f = Y - X \) on the origin \( S = S(g) = \{0\} \subset \mathbb{R}^2 \), where \( Q = Q(g) = Q(1 - X^2 - Y^2, -XY, X - Y, Y - X^2) \subset \mathbb{R}[X, Y] \). In this case \( \text{supp } Q = \frac{1}{2} \text{supp } \Theta(0), \) and thus from Theorem 3.9 there is no gap and \( f - f^*_\text{SoS,d} \in Q_{2d}(g) \) for all \( d \). Then, if there is SoS finite convergence, \( Y - X = f - f^* \in Q(g) \). Since \( X - Y \in Q(g) \), finite convergence would imply that \( X - Y \in Q(g) \cap -Q(g) = \text{supp } Q(g) = (0), \) a contradiction. Therefore there is no SoS finite convergence, and by strong duality there is no MoM finite convergence as well. This example shows that [Nie13c, Th. 4.1] cannot be extended from preorders to quadratic modules in general, but only when \( \text{supp } Q \) is a zero-dimensional ideal (see Theorem 4.10).

The next example shows that SoS and MoM hierarchies for polynomial optimization on algebraic curves do not necessarily have the finite convergence property. For the definition of graded basis, see the paragraph before Proposition 3.10.

**Example A.2** ([Sch00]). Let \( C \subset \mathbb{R}^n \) be a smooth connected curve of genus \( \geq 1 \), with only real points at infinity (e.g. the plane cubic defined by \( Y^2 = X^3 - X \)). Let \( h = h_1, \ldots, h_s \subset \mathbb{R}[X] \) be a graded basis of \( I = I(C) \). Then there exists \( f \in \mathbb{R}[X] \) such that the SoS hierarchy \( Q_{2d}(\pm h) \) and the MoM hierarchy \( L_{2d}(\pm h) \) have no finite convergence and are not exact.

Indeed by [Sch00], Th. 3.2], there exists \( f \in \mathbb{R}[X] \) such that \( f \geq 0 \) on \( C = S(\pm h) \), which is not a sum of squares in \( \mathbb{R}[C] = \mathbb{R}[X]/I \). Consequently, \( f \notin \Sigma^2[X] + I = Q(\pm h) \). As \( f \geq 0 \) on \( C \), its infimum \( f^* \) is non-negative and we also have \( f - f^* \notin Q(\pm h) \).
Using Proposition 3.10 we deduce that $Q_{2d}(\pm h)$ is closed, that there is no duality gap and that the supremum $f^*_{\text{SoS},2d}$ is reached. Thus if the MoM hierarchy has finite convergence then the SoS hierarchy also has finite convergence and $f - f^* \in Q_{2d}(\pm h)$ for some $d \in \mathbb{N}$. But this is in contradiction with the previous paragraph, showing that the SoS and the MoM hierarchies have no finite convergence.

In dimension 2, there are also cases where the SoS and MoM hierarchies cannot have finite convergence or be exact.

**Example A.3 (Mar08).** Let $g_1 = X_1^3 - X_2^2, g_2 = 1 - X_1$. Then $S = S(g)$ is a compact semialgebraic set of dimension 2 and $T(g)$ is Archimedean. We have $f = X_1 \geq 0$ on $S$ but $X_1 \notin T(g)$ (see Mar08 Example 9.4.6(3)). The infimum of $f$ on $S$ is $f^* = 0$. Assume that we have MoM finite convergence. Using for instance Proposition 3.10 $Q_{2d}(\Pi g)$ is closed, the supremum $f^*_{\text{SoS},2d}$ is reached and strong duality holds: $f^*_S = f^*_{\text{MoM},2d} = f^* = 0$. Then $f - f^* = f \in T(g)$: but this is a contradiction. Therefore, the hierarchies $Q_{2d}(\Pi g) = Q_{2d}(g_1, g_2, g_1, g_2)$ and $L_{2d}(\Pi g) = L_{2d}(g_1, g_2, g_1, g_2)$ cannot have finite convergence and thus cannot be exact for $f = X_1$.

The next example shows that non-finite convergence and non-exactness is always possible for semialgebraic sets of dimension $\geq 3$.

**Example A.4.** Let $n \geq 3$. Let $Q(g)$ be an Archimedean quadratic module generated by $g_1, \ldots, g_8 \in \mathbb{R}[X]$ such that $S(g) \subset \mathbb{R}^n$ is of dimension $m \geq 3$ and let $h$ be a graded basis of $\sqrt[3]{\text{supp } Q(g)}$ (in particular $h = 0$ if $m = n$, i.e. $S(g)$ is of maximal dimension). Then there exists $f \in \mathbb{R}[X]$ such that the SoS hierarchy ($Q_{2d}(g, \pm h))_{d \in \mathbb{N}}$ and MoM hierarchy ($L_{2d}(g, \pm h)$) do not have the finite convergence property (and thus are not exact).

Indeed by Proposition 3.10 $f^*_{\text{SoS},2d} = f^*_{\text{MoM},2d}$ for $d$ big enough and the supremum $f^*_{\text{SoS},2d}$ is reached. By Sch00 Prop. 6.1 for $m \geq 3$, Pos($S(g) \supseteq Q(g) + (h)$). So let $f \in \text{Pos}(S(g) \setminus Q(g) + (h)$ and let $f^*$ be its minimum on $S(Q)$. Suppose that $f - f^* \in Q(g) + (h)$, then $f \in Q(g) + (h) + f^* = Q(g) + (h)$, a contradiction. Then the SoS and the MoM hierarchy do not have the finite convergence property (and they are not exact).

**SoS exactness, no MoM exactness.**

**Example A.5.** We consider in this example the unconstrained case. We want to find the global minimum of $f = X_1^2 \in \mathbb{R}[X_1, \ldots, X_n] = \mathbb{R}[X]$ for $n \geq 3$. Let $d \geq 2$, $X' = (X_2, \ldots, X_n)$ and $\lambda \in \Sigma^2[X']$ such that $\lambda \in M(\mathbb{R}^{n-1})[\delta]$. Such a linear functional exists because when $n > 2$ there are non-negative polynomials in $\mathbb{R}[X]$ which are not sum of squares, such as the Motzkin polynomial (see [Rez96]). As $\Sigma^2[X']$ is closed, such a polynomial can be separated from $\Sigma^2[X']$ by a linear functional $\lambda \in \Sigma^2[X']$, which cannot be the truncation of a measure. Define $\lambda : h \mapsto \langle \lambda, h \rangle = \langle \lambda, h(0, X_2, \ldots, X_n) \rangle$. We have $\lambda \in \Sigma^2[X']$ since $\lambda \in \Sigma^2[X']$. Obviously $\langle \lambda, f \rangle = 0 = f^*$ (the minimum of $X_1^2$). $f - f^* = X_1^2 \in \Sigma^2$ and the SoS hierarchy is exact. Since $\lambda$ is represented by a measure if and only if $\lambda$ is represented by a measure, the MoM hierarchy cannot be exact.

**Example A.6** (see also Sch05a Ex. 3.2, Sch05b Rem. 3.15, Example 3.5, Example A.1). We want to minimize the constant function $f = 1$ on the origin $S = S(g) = \{0\}$, where $Q = Q(g) = Q(1 - X^2 - Y^2, -XY, X - Y, Y - X^2) \subset \mathbb{R}[X, Y]$. In this case $\text{supp } Q = \sqrt[3]{\text{supp } Q} = (0)$. Notice that the SoS hierarchy is exact and the MoM hierarchy has finite convergence, since $f \in Q_{2d}(g)$. Now suppose that the MoM hierarchy is exact, i.e. $L_{2d}^{\text{min}}(f; g)[2k] = L_{2d}^{\text{min}}(g)[2k] \subset M(1)(S)[2k] = [e^0_{2k}]$. Then for $\lambda' \in L_{2d}(g)$ we have $(\text{Ann}_k(\lambda')) = (\text{Ann}_k(e_0)) = (X, Y)$. But from Theorem 3.14 we know that for $d, k$ big enough $(\text{Ann}_k(\lambda')) = \sqrt[3]{\text{supp } Q} = (0)$, a contradiction. Then the MoM hierarchy is not exact. Moreover the flat truncation property is not satisfied in this case: see Theorem 3.4.
We investigate concretely this example for \( d = 1 \). We show in Figure 1 the plot of \( \mathcal{L}_2(\mathbf{g})^{[1]} \), that is the pseudo-moments of degree one of the linear functionals in the dual cone of \( \mathcal{Q}_2(\mathbf{g}) \). Notice that this is an outer approximation of \( \mathbf{e}_{(0,0)} \in \mathcal{L}_2(\mathbf{g})^{[1]} \) or, identifying moments of degree one with points of \( \mathbb{R}^n \), a convex outer approximation of \( S = \{(0,0)\} \).

One can also verify explicitly that \( \mathcal{L}_2(\mathbf{g})^{[1]} \) has nonempty interior, as for instance \( \lambda = \lambda(\varepsilon) \) defined by \( \lambda_{10} = 2\varepsilon, \lambda_{01} = \varepsilon, \lambda_{20} = \varepsilon, \lambda_{11} = -\varepsilon^2 \) and \( \lambda_{02} = \frac{1}{2} \) lies in the interior of \( \mathcal{L}_2(\mathbf{g}) \) for \( \varepsilon > 0 \) small enough.

Notice that \( \mathcal{L}_2(\mathbf{g})^{[1]} \supset \mathcal{L}_3(\mathbf{g})^{[1]} \supset \mathcal{L}_4(\mathbf{g})^{[1]} \supset \cdots \supset \{\mathbf{e}_{(0,0)}^{[1]}\} \), and we have convergence since \( \mathcal{Q}(\mathbf{g}) \) is Archimedean. This nested outer approximations never coincide with \( \{\mathbf{e}_{(0,0)}^{[1]}\} \), as we have proven before.

Figure 1: A generic point \( \lambda^* \in \mathcal{L}_2^{(1)}(\mathbf{g})^{[1]} \) and moment outer approximations of \( \mathcal{L}_1^{(1)}(\mathbf{g})^{[1]} = \{\mathbf{e}_{(0,0)}^{[1]}\} \).

SoS finite convergence, MoM exactness.

Example A.7. Let \( f = (X^4Y^2 + X^2Y^4 + Z^6 - 2X^2Y^2Z^2) + X^8 + Y^8 + Z^8 \in \mathbb{R}[X,Y,Z] \). We want to optimize \( f \) over the gradient variety \( \mathcal{V}_\mathbb{R}(\frac{\partial f}{\partial X}, \frac{\partial f}{\partial Y}, \frac{\partial f}{\partial Z}) \) which is zero-dimensional (see [NDS06]). By Theorem 4.10 the flat truncation is satisfied and the MoM hierarchy is exact, and by Theorem 3.9 and remark below the SoS has the finite convergence property (notice that \( \mathcal{Q}(\pm \frac{\partial f}{\partial X}, \pm \frac{\partial f}{\partial Y}, \pm \frac{\partial f}{\partial Z}) = T(\pm \frac{\partial f}{\partial X}, \pm \frac{\partial f}{\partial Y}, \pm \frac{\partial f}{\partial Z}) \) is Archimedean since \( \mathcal{V}_\mathbb{R}(\frac{\partial f}{\partial X}, \frac{\partial f}{\partial Y}, \frac{\partial f}{\partial Z}) \) is compact). But the SoS hierarchy is not exact, as shown in [NDS06].

Example A.8. Let \( f = X_1 \). We want to find its value at the origin, defined by \( ||X||^2 = 0 \). As proved in [Nie13c] there is finite convergence but not exactness for the SoS hierarchy. On the other hand by Theorem 4.10 the flat truncation property is satisfied and the MoM hierarchy is exact.
