We consider a scalar-tensor model of dark energy with Gauss-Bonnet and non-minimal couplings. Exact cosmological solutions were found in absence of potential, that give equations of state of dark energy consistent with current observational constraints, but with different asymptotic behaviors depending on the couplings of the model. A detailed reconstruction procedure is given for the scalar potential and the Gauss-Bonnet coupling for any given cosmological scenario. Particularly, we consider conditions for the existence of a variety of cosmological solutions with accelerated expansion, including quintessence, phantom, de Sitter, Little Rip. For the case of quintessence and phantom we have found a scalar potential of the Albrecht-Skordis type, where the potential is an exponential with a polynomial factor.

I. INTRODUCTION

A significant number of extensions of general relativity modifying the behavior of Einstein gravity at cosmic scales, have been introduced lately in order to explain the observed accelerated expansion of the universe [1]-[7]. These models range from modifications of the source terms that involve scalar fields of different nature like quintessence, phantom, tachyon, dilaton (see [8]-[11] for review), including different couplings of scalar field to curvature (scalar-tensor theories) [12]-[20], to modifications of the geometrical terms involving curvature, known as modified gravity theories [21]-[27]. Among all possible explanations for the observed cosmic acceleration the scalar-tensor theories are widely considered since the couplings of scalar fields to curvature naturally appear in the process of quantization on curved space time [28, 29], from compactifications of higher dimensional gravity theories [30], in the next to leading order corrections in the α′ expansion of the string theory [31-33]. Perhaps the most studied and the simplest one of these couplings is the non-minimal coupling of the type $\xi R \phi^2$. The role of this coupling in the dark energy (DE) problem has been studied in different works, including the constraint on $\xi$ by solar system experiments [12], the existence and stability of cosmological scaling solutions [13, 14], perturbative aspects and incidence on CMB [34, 35], tracker solutions [36], observational constraints and reconstruction [37-39], the coincidence problem [40], super acceleration and phantom behavior [41]-[45], and asymptotic de Sitter attractors [46]. Another interesting interaction that gives good results in the study of the dark energy is the coupling between the scalar field and the Gauss-Bonnet (GB) invariant. Although the GB term is topologically invariant in four dimensions, nevertheless it affects the cosmological dynamics when it is coupled to a scalar field, contributing second order differential terms to the equations of motion. This coupling has been proposed to address the dark energy problem in [47], showing attractive features like preventing the Big Rip singularity in phantom cosmology. Different aspects of accelerating cosmologies with GB correction have been discussed in [48]-[58]. All these studies demonstrate that it is quite plausible that the scalar-tensor couplings predicted by fundamental theories may become important at current, low-curvature universe.

In this paper we consider a scalar-tensor model that contains the above mentioned two couplings: the non-minimal coupling to the curvature and to the Gauss-Bonnet invariant, and analyze the role of these couplings in the late time universe. The understanding of the effect of these non-minimal couplings could provide clues about how the fundamental theories at high energies manifest at cosmological scales. We consider two different approaches: first we find exact cosmological solutions in absence of potential, that give consistent description of different DE scenarios. It is shown that depending on values of the couplings, the universe can be currently undergoing a transition from quintessence to phantom phase or from phantom to quintessence phase. In the second approach we reconstruct the potential and the GB coupling for various interesting cosmological scenarios beginning with power-law expansion and considering also Big Rip and Little Rip solutions. For power-law solutions we found a potential that was considered before in connection with low energy limit of M-theory [59, 60]. The paper is organized as follows. In Sec. II we introduce the model of the scalar field with non-minimal and GB couplings and give a detailed reconstruction scheme for a given cosmological scenario. In section III we present exact solutions of the model with zero potential and study the behavior of the corresponding equations of state. In sec. IV we present some samples of late time cosmologies and make reconstruction of the scalar potential and GB coupling. Sec. V is dedicated to some summary and discussion.

II. THE SCALAR-TENSOR MODEL AND FIELD EQUATIONS

Let’s start with the action for the scalar field where in addition to the GB coupling we consider the non-minimal coupling of the scalar field to curvature. As will be seen below, the non-linear character of the cosmological equations makes the integration of the same ones very difficult for a given set of initial conditions. Nevertheless given that we know in advance some cosmological scenarios that represent probable states of expansion of the universe, we can deal with the inverse problem: for a given cosmological solution try the reconstruction of the model. Below we give a general approach to reconstruct the scalar-tensor model with non-minimal and GB couplings for any given cosmological scenario [48]. The action for the model with scalar field and matter is given by

\[
S_\phi = \int d^4x \sqrt{-g} \left[ \frac{1}{2\kappa^2} R - \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \frac{1}{2} \xi R \phi^2 - V(\phi) - \eta(\phi)G + L_m \right],
\]

where \( \kappa^2 = 8\pi G \), \( G = R^2 - 4R_{\mu\nu}R^{\mu\nu} + R_{\mu\nu\lambda\rho}R^{\mu\nu\lambda\rho} \) is the GB invariant, and \( L_m \) is the Lagrangian of perfect fluid with energy density \( \rho_m \) and pressure \( P_m \). We will consider the spatially-flat Friedmann-Robertson-Walker (FRW) metric.

\[
ds^2 = -dt^2 + a(t)^2 \sum_{i=1}^{3} (dx_i)^2
\]

The Friedman equations with Hubble parameter \( H = \dot{a}/a \) are

\[
H^2 = \frac{\kappa^2}{3} \left( \frac{1}{2} \dot{\phi}^2 + V(\phi) + 6\xi \dot{H} \phi + 3\xi H^2 \phi^2 \right.
\]

\[
+ 24H^3 \frac{d\eta}{d\phi} \dot{\phi} + \rho_m \right)
\]

\[
-2\dot{H} - 3H^2 = \kappa^2 \left[ \frac{1}{2} \dot{\phi}^2 - V(\phi) - 2\xi \left( \dot{\phi}^2 + \dot{\phi} \dot{\phi} \right) \right.
\]

\[
-4\xi H \phi \dot{\phi} - \xi \left( 2\dot{H} + 3H^2 \right) \phi^2 - 8H^2 \frac{d\eta}{d\phi} \dot{\phi}
\]

\[
-8H^2 \frac{d\eta}{d\phi} \dot{\phi}^2 - 16H \frac{d\eta}{d\phi} \dot{\phi} - 16H^3 \frac{d\eta}{d\phi} \dot{\phi}
\]

\[
+ P_m \left)
\right]
\]

(5)

Deleting the potential from eqs. (3) and (4) one finds

\[
\rho_m + P_m = -2\xi H \phi \ddot{\phi} - 8H^3 \frac{d\eta}{d\phi} \ddot{\phi} - \dot{\phi}^2 + 2\xi \dot{\phi}^2
\]

\[
+ 8H^2 \frac{d^2\eta}{d\phi^2} \ddot{\phi}^2 + 2\xi \ddot{\phi} + 8H^2 \frac{d\eta}{d\phi} \dot{\phi}
\]

\[
- \frac{2}{\kappa^2} \dot{H} + 2\xi \dot{\phi}^2 \dot{H} + 16H \dot{H} \frac{d\eta}{d\phi} \dot{\phi} \]

(6)

which can be written in the form

\[
\frac{1}{2} \left( \rho_m + P_m \right) = \xi \dot{\phi} \ddot{\phi} - \xi H \phi \dot{\phi} - \left( \frac{1}{2} - \xi \right) \dot{\phi}^2 - \left( \frac{1}{\kappa^2} - \xi \phi^2 \right) \dot{H}
\]

\[
+ 4 \left( H^2 \frac{d^2\eta}{dt^2} + 2H \dot{H} \frac{d\eta}{dt} - H^3 \frac{d\eta}{dt} \right)
\]

(7)

If additionally we have in mind that

\[
4a \frac{d}{dt} \left[ \frac{H^2 \frac{d\eta}{dt}}{a} \right] = H^2 \frac{d^2\eta}{dt^2} + 2H \dot{H} \frac{d\eta}{dt} - H^3 \frac{d\eta}{dt}
\]

then, the eq. (5) can be written as

\[
4a \frac{d}{dt} \left[ \frac{H^2 \frac{d\eta}{dt}}{a} \right] = \frac{1}{2} \left( \rho_m + P_m \right) + \left( \frac{1}{2} - \xi \right) \dot{\phi}^2 + \left( \frac{1}{\kappa^2} - \xi \phi^2 \right) \dot{H}
\]

\[
- \xi \dot{\phi} \ddot{\phi} + \xi H \phi \dot{\phi}
\]

(8)

Let’s define the following function

\[
R(t) = \frac{1}{2} \left( \rho_m + P_m \right) + \left( \frac{1}{2} - \xi \right) \dot{\phi}^2 + \left( \frac{1}{\kappa^2} - \xi \phi^2 \right) \dot{H} - \xi \dot{\phi} \ddot{\phi}
\]

\[
+ \xi H \phi \dot{\phi}
\]

(9)

which allows to rewrite the Eq. (8) in the compact form:

\[
R(t) = 4a \frac{d}{dt} \left[ \frac{H^2 \frac{d\eta}{dt}}{a} \right]
\]

(10)

This equation can be solved with respect to \( \eta \) as

\[
\eta(t) = \frac{1}{4} \int_0^t dt_1 \frac{a(t_1)}{H^2(t_1)} \int_0^{t_1} dt_2 \frac{R(t_2)}{a(t_2)}
\]

(11)

From (3) one can write the potential as

\[
V(t) = S(t) - 24H^3 \frac{d\eta}{dt}
\]

(12)

where the function \( S(t) \) is defined as

\[
S(t) = \frac{3}{\kappa^2} H^2 - 3\xi H^2 \phi^2 - 6\xi H \phi \dot{\phi} - \frac{1}{2} \dot{\phi}^2 - \rho_m
\]

(13)

and using the Eq. (11) one finds
\[ V(t) = S(t) - 6a(t)H(t) \int_{t_1}^{t} \frac{R(t_1)}{a(t_1)} \, dt_1 \quad (14) \]

The Eqs. (11) and (14) allow to reconstruct the model for a given scalar field \( \phi(t) \) and Hubble function \( H(t) \). In order to express the potential \( V \) and the Gauss-Bonnet coupling \( \eta \) as functions of the scalar field, we can assume that

\[ t = f(\phi) \]
\[ a = a_0e^{g(t)}, \quad H = g'(t) \quad (15) \]

where \( f \) and \( g \) are given functions. Replacing (15) in (11) and (14) we find

\[ \eta(\phi) = \frac{1}{4} \int_{\phi}^{\phi_1} f'(\phi_1) e^{g(f(\phi_1))} \left[ g'(f(\phi_1)) \right] \, d\phi_1 \]
\[ \times \int_{\phi_1}^{\phi_2} f'(\phi_2) e^{-g(f(\phi_2))} R(f(\phi_2)) \, d\phi_2 \]
\[ \quad \times e^{-g(f(\phi_1))} R(f(\phi_1)) \quad (16) \]

These equations allow to reconstruct the model by given \( f \), \( g \). In order to have explicit solutions for \( R(f(\phi)) \) and \( S(f(\phi)) \) we need to take into account the conservation equation for the matter component with constant equation of state \( w \)

\[ \rho_m + 3H(1 + w)\rho_m = 0 \quad \Rightarrow \quad \rho_m = \rho_m a^{3(1+w)} \]

From \( a = a_0e^{g(t)} \), follows

\[ \rho_m = g_0 e^{-3(1+w)g(t)} \quad \text{where} \quad g_0 = \rho_m a_0^{-3(1+w)} \]

This way it is obtained that

\[ R(f(\phi)) = \frac{\xi \phi'g'(f(\phi))}{f'(\phi)} - \frac{\xi}{f'(\phi)} + \frac{1}{2f'(\phi)^2} + \frac{\xi \phi''g'(f(\phi))}{f'(\phi)^2} \]
\[ + \frac{g''(f(\phi))}{\kappa^2} + \frac{g_0}{2}(w + 1)e^{-3(\omega + 1)g(f(\phi))} \]
\[ - \xi \phi^2g''(f(\phi)) \quad (18) \]

\[ S(f(\phi)) = -\frac{6\xi \phi'g'(f(\phi))}{f'(\phi)} - \frac{1}{2f'(\phi)^2} + \frac{3g'(f(\phi))^2}{\kappa^2} \]
\[ -3\xi \phi^2g'(f(\phi))^2 - g_0 e^{-3(\omega + 1)g(f(\phi))} \quad (19) \]

The Eqs. (18) and (19) after being replaced in the Eqs. (16) and (17) give the reconstructed model by known functions \( f \) and \( g \). Therefore any cosmological scenario for the model (1) encoded in the functions \( f(\phi) \) and \( g(t) \) with the GB coupling and potential given by (16) and (17) can be realized. In section IV we provide some important examples, including cosmologies with phase of super-acceleration. In the next section we consider the model without potential, find exact solutions and analyze possible late time cosmological scenarios.

### III. THE DYNAMICS WITHOUT POTENTIAL. EXACT SOLUTIONS

As we will show, the model contains interesting solutions even in absence of the scalar potential. To this end, we write down the equation of motion for the scalar field

\[ \ddot{\phi} + 3H \dot{\phi} + \frac{dV}{d\phi} + 6\xi(2H^2 + \dot{H}) \phi + 24H^2 \left( H^2 + \dot{H} \right) \frac{d\eta}{d\phi} \quad (20) \]

Setting \( V = 0 \) and turning to the e-folding variable \( x = \ln a \) we can write the Eqs. (3) and (20) in the form

\[ H^2 = \frac{\kappa^2}{3} \left[ \frac{1}{2} \left( \frac{d\phi}{dx} \right)^2 + 3\xi H^2 \left( 2\frac{d\phi}{dx} + \phi^2 \right) \right. \]
\[ + 24H^2 \left( \frac{d\eta}{dx} \right) \]
\[ \frac{d}{dx} \left[ H^2 \left( \frac{d\phi}{dx} \right)^2 + 6H^2 \left( \frac{d\phi}{dx} \right)^2 + 6\xi \left( 4H^2 + \frac{dH^2}{dx} \right) \frac{d\phi}{dx} \right. \]
\[ + 24H^2 \left( \frac{d\eta}{dx} \right) \]
\[ = 0 \quad (22) \]

In order to integrate these equations we consider the following expression for the GB coupling

\[ \frac{d\eta}{dx} = \frac{1}{H^2} \left( g_1 + g_2 \phi^2 \right) \quad (23) \]

By using this expression for the GB coupling, the Eqs. (21) and (22) reduce to the following

\[ \left( \frac{d\phi}{dx} \right)^2 + 12\xi \frac{d\phi}{dx} + 6(\xi + 8g_2) \phi^2 + 48g_1 - \frac{6}{\kappa^2} = 0 \quad (24) \]

and

\[ \left[ \frac{d}{dx} \left( \frac{d\phi}{dx} \right)^2 + 6 \left( \frac{d\phi}{dx} \right)^2 + 24\xi \frac{d\phi}{dx} + 48 \left( g_1 + g_2 \phi^2 \right) \right] H^2 \]
\[ + \left[ \left( \frac{d\phi}{dx} \right)^2 + 6\xi \frac{d\phi}{dx} + 24 (g_1 + g_2 \phi^2) \right] \frac{dH^2}{dx} \]
\[ = 0 \quad (25) \]

by restricting the constant \( g_1 \) to the value \( g_1 = 1/(8\kappa^2) \), the last term in (24) disappears, reducing it to

\[ \frac{d\phi}{dx} = \left( -6\xi \pm \sqrt{6\xi(6\xi - 1) - 48g_2} \right) \phi, \quad (26) \]
which gives the solution

$$\phi(x) = \phi_0 e^{-\lambda x}, \quad \lambda = 6\xi \pm \sqrt{6\xi (6\xi - 1) - 48g_2}$$  \hspace{1cm} (27)$$

Replacing this solution into the equation of motion (25) leads to the following equation for the Hubble parameter

$$\left( \lambda^2 - 6\xi \lambda + 24g_2 + \frac{3}{\kappa^2 \phi_0^2 e^{2\lambda x}} \right) \frac{dH^2}{dx} + 2 \left( -\lambda^3 + 3\lambda^2 - 12\xi \lambda + 24g_2 + \frac{3}{\kappa^2 \phi_0^2 e^{2\lambda x}} \right) H^2 = 0$$

(28)

After solving this equation we can find the dark energy equation of state (EOS) as

$$w_{DE} = -1 - \frac{1}{3H^2} \frac{dH^2}{dx}$$  

(29)

In order to integrate the equation (28) we can assume some simplifications. First we can note that at far future ($x \gg 1$) if $\lambda > 0$, the exponential terms will dominate over the constants and the solution of the equation reduces to

$$H^2 = H_0^2 e^{-2x}$$  \hspace{1cm} (30)

where $H_0$ is the integration constant. The EOS for this solution is the constant $w = -1/3$, which corresponds to the divide between the decelerated and accelerated expansion. This means that (provided $\lambda > 0$) even if currently the EOS is close to $w_0 = -1$, then at far future the dark energy EOS tends to $w = -1/3$. On the other hand, if $\lambda < 0$ then at far future the exponential terms in the Eq. (28) become subdominant and the solution to the equation will depend on the constant terms and reduces to

$$H^2 = H_0^2 \exp \left( \frac{2\lambda^3 - 6\lambda^2 + 24\xi \lambda - 48g_2}{\lambda^2 - 6\xi \lambda + 24g_2} x \right)$$  \hspace{1cm} (31)

which gives the constant EOS

$$w = -1 - \frac{1}{3} \left( \frac{2\lambda^3 - 6\lambda^2 + 24\xi \lambda - 48g_2}{\lambda^2 - 6\xi \lambda + 24g_2} \right)$$  \hspace{1cm} (32)

Thus depending on the values of $\xi$ and $g_2$, at far future the EOS tends asymptotically to the cosmological constant if $2\lambda^3 - 6\lambda^2 + 24\xi \lambda - 48g_2 = 0$, or can fall below the phantom divide if the second term in Eq. (32) is negative. It follows then that the model (1) can describe quintessence and phantom phases even without potential. To see this more clearly lets consider the following restriction

$$2\lambda^3 - 6\lambda^2 + 24\xi \lambda - 48g_2 = 0$$  \hspace{1cm} (33)

which simplifies the Eq. (28) and leads to the solution

$$H^2 = h_0^2 \left[ \kappa^2 \phi_0^2 (\lambda^2 - 6\xi \lambda + 24g_2) + 3e^{2\lambda x} \right]^{-1/\lambda}$$  \hspace{1cm} (34)

where $h_0^n$ is the integration constant. This solution gives the following dark energy EOS

$$w = -1 + \frac{2 e^{2\lambda x}}{\kappa^2 \phi_0^2 (\lambda^2 - 6\xi \lambda + 24g_2) + 3e^{2\lambda x}}$$  \hspace{1cm} (35)

lets assume that in the current epoch ($x = 0$) the DE EOS parameter takes the value $w_0$. Then setting $x = 0$ in (35) one finds the following relation

$$\kappa^2 \phi_0^2 (\lambda^2 - 6\xi \lambda + 24g_2) = -\frac{3w_0 + 1}{w_0 + 1}$$  \hspace{1cm} (36)

By replacing $\xi$ from (27) and $g_2$ from the restriction (33) one can rewrite the Eq. (36) as

$$\frac{2\lambda^3 - 6\lambda^2 + 24\xi \lambda - 48g_2}{2\lambda + 1} = -\frac{1}{\kappa^2 \phi_0^2 (w_0 + 1)}$$  \hspace{1cm} (37)

The r.h.s. of this equation is positive whenever $-1 < w_0 < -1/3$, i.e. when the current EOS parameter is in the quintessential phase. Corresponding to this, the l.h.s. of the equation is positive if $\lambda > 1$ or $\lambda < -1/2$. If the current EOS is $w_0 < -1$ or $w_0 > -1/3$, then the r.h.s. of eq. (37) negative and the corresponding l.h.s. becomes negative for $\lambda$ in the interval $-1/2 < \lambda < 1$. We can see the behavior of the initial condition in the EOS parameter depending on the initial conditions on the scalar field $\phi_0$ in Fig. 1. In the interval $-1/2 < \lambda < 1$, where the

![FIG. 1. The initial conditions for the current value of the DE EOS parameter $w_0$ as function of $\kappa \phi_0$ for some values of $\lambda$. The horizontal lines correspond to $w_0 = -1/3$ at $\lambda = 1$ and the cosmological constant $w_\Lambda = -1$ at $\lambda = -1/2$, which are independent of the initial value $\kappa \phi_0$. For $w_0$ in the interval $-1 < w_0 < -1/3$ the allowed values of $\lambda$ are $\lambda > 1$ or $\lambda < -1/2$.](image)
The EOS for this solution is given by

$$H^2 = h_0^2 e^{-\frac{x}{\xi}} [\kappa^2 \phi_0^2 \beta + 3e^{2\lambda x}]^{-\frac{2 \beta - 1}{2 \beta + 1}},$$ (38)

where $h_0^2$ is the integration constant and

$$\beta = \lambda^2 - 6\xi \lambda + 24g_2, \quad \gamma = -2 \lambda^3 + 6\lambda^2 - 24\xi \lambda + 48g_2.$$

The EOS for this solution is given by

$$w = -1 + \frac{\gamma (\kappa \phi_0)^2}{3\beta (\kappa \phi_0)^2 + 9e^{2\lambda x}}$$ (39)

which depending on the sign of $\lambda$ evolves between the values:

$$\lim_{x \to -\infty} w = -1 + \frac{\gamma}{3\beta} \quad \text{and} \quad \lim_{x \to \infty} w = -\frac{1}{3} \quad \text{for} \quad \lambda > 0$$

and

$$\lim_{x \to -\infty} w = -\frac{1}{3} \quad \text{and} \quad \lim_{x \to \infty} w = -1 + \frac{\gamma}{3\beta} \quad \text{for} \quad \lambda < 0.$$

It is noted that these limits do not depend on the initial value of the scalar field $\phi_0$. It can be seen from these equations that the solution can contain the phantom phase if one of the parameters $\beta$ or $\gamma$ is negative.

Let’s consider each case separately. If we assume $\beta < 0$ and $\gamma > 0$, then the first $x$-dependent factor in (38) increases exponentially with $x$ but the power of the second factor becomes negative, which leads to divergence at some point where $\beta(\kappa \phi_0)^2 = -3e^{2\lambda x}$. So the solutions with $\beta < 0$ give rise to Big Rip singularities. These singularities can be avoided if we consider the second case where $\beta > 0$ and $\gamma < 0$. In this case the second factor in (38) is always positive independently of the sign of the power, giving a solution that is always finite with the advantage that can describe a phantom universe.

To illustrate the behavior of the solution (38), in Fig. 3 we plot the EOS as function of the redshift $z$ for some values of the parameters. We can see that these curves fit very well to the observed behavior of the DE EOS. According to the curves for $\lambda = 1/8, 1/16$, the expansion due to DE is currently undergoing the transition from phantom to quintessence phase, and the curves for $\lambda = -1/8, -1/16$ describe an expansion currently going through the transition from quintessence to phantom phase. There is also possible to have adequate behavior of DE for small values of the coupling $\xi$ as is shown in Figs. 4 and 5, where we show solutions with "almost constant" EOS or with almost constant slope in a wide interval of $z$. The EOS

![FIG. 2. The evolution of the DE EOS parameter $w$ as function of $z$ for $\xi = (2/15, -3/14, -7/6, -3/2)$ which give $(\lambda = 2, 3, -1, -3/2)$ and $w_0 \approx -0.95, -0.98, -0.97, -0.98$ respectively, for $k\phi_0 = 4$. Though the current values are very similar, the DE evolves to different scenarios depending on $\xi$ (which defines the sign of $\lambda$).](image)

![FIG. 3. The behavior of the DE EOS $w$ as function of the redshift. The initial value of the scalar field is $k\phi_0 = 2$ and the current value is $w_0 = -1$. For $\lambda = (1/8, -1/8, 1/16, -1/16)$ the corresponding coupling parameters take the values $\xi = (5, -5, 10, -10)$ and $g_2 = 0.28$ for all cases.](image)

![FIG. 4. The DE EOS $w$ as function of the redshift for small parameters. In all cases $\lambda > 0$ and the initial value of the scalar field is $k\phi_0 = 2$. The curves show different current EOS parameters $w_0$, but all of them are close to $-1$, and present transitions from phantom to quintessence phase in the past ($w_0 > -1$), the present ($w_0 = -1$) and the future ($w_0 < -1$).](image)
ior very close to the cosmological constant up to recent epochs.

![Graph](image)

**FIG. 5.** Fig. 5 The DE EOS $w$ as function of the redshift for $\lambda < 0$. In all cases the initial value of the scalar field is $\phi_0 = 4$. The curves cover different behaviors of the EOS, but all of them in an acceptable range of values according to the data. Note the transitions from quintessence to phantom phase in the past ($w_0 < -1$), the present ($w_0 = -1$) and the future ($w_0 > -1$). The horizontal line corresponds to the cosmological constant.

## IV. RECONSTRUCTING QUINTESSENCE AND PHANTOM SCENARIOS

In an scenario with dominance of DE we assume the scalar field with non-minimal and GB couplings as the responsible for the energy content of the universe, which is achieved in the model (1) by setting $L_m = 0$ or in the subsequent equations, by making $g_0 = 0$. In this section we will discuss some important solutions that give appropriate description of late-time universe. We give explicit examples of reconstructed scalar potential and GB coupling for an accelerated universe in quintessence and phantom phases, with Big Rip and Little Rip singularities. The phantom cosmology can be realized in the present model without resorting to ghost scalar fields.

### A. Quintessential power-law

In the FRW background the power-law solutions are of special interest because they represent asymptotic or intermediate states among all possible cosmological evolutions. Let’s consider the following functions

$$f(\phi) = t_0 e^{\phi/\phi_0}, \quad g(t) = p \ln \left( \frac{t}{t_0} \right)$$

which according to (15) lead to

$$H = \frac{p}{t}, \quad \phi = \phi_0 \ln \left( \frac{t}{t_0} \right)$$

Replacing (40) in (16) one finds the GB coupling as

$$\eta(\phi) = \frac{t_0^2}{\kappa^2} \left[ c_0(p, \xi) + c_1(p, \xi)\phi + c_2(p, \xi)\phi^2 \right] e^{2\phi/\phi_0}$$

where

$$c_0(p, \xi) = \frac{2p(p + 1)^2 - (1 - \xi + 2p + p^2 - 3p^2\xi)\kappa^2\phi_0^2}{16p^2(1 + p)^3},$$

$$c_1(p, \xi) = -\frac{(1 + 3p)\xi\kappa^2\phi_0}{8p(1 + p)},$$

$$c_2(p, \xi) = -\frac{\xi\kappa^2}{8p(1 + p)}$$

and the expression for the potential (17) becomes

$$V(\phi) = \frac{1}{\kappa^2t_0^2} \left[ d_0(p, \xi) + d_1(p, \xi)\phi + d_2(p, \xi)\phi^2 \right] e^{-2\phi/\phi_0}$$

where

$$d_0(p, \xi) = \frac{6p^2(p + 1)^2(p - 1) + (5p^3 + (9 + 24\xi)p^2 + 3p - 1)\kappa^2\phi_0^2}{2(1 + p)^3},$$

$$d_1(p, \xi) = \frac{12p^2\xi\kappa^2\phi_0}{(1 + p)^2},$$

$$d_2(p, \xi) = -\frac{3(p - 1)p^2\xi\kappa^2}{1 + p}$$

The power-law solution can also be realized by the following functions

$$f(\phi) = t_0 \frac{\phi}{\phi_0}, \quad g(t) = p \ln \left( \frac{t}{t_0} \right)$$

which lead to the following Gauss-Bonnet coupling

$$H = \frac{p}{t}, \quad \phi = \phi_0 \ln \left( \frac{t}{t_0} \right)$$

where
and the scalar potential

\[ V(\phi) = \frac{1}{2(p^2 - 1)t_0^2 \kappa^2 \phi_0^2} \left[ 6p^2(p - 1)^2 \phi_0^2 - (p + 1)((6p(p - 3)\xi - 5)p - 1)\kappa^2 \phi_0^2 \phi^2 \right] \]  

(46)

It can be seen that for large \( \phi \) this potential has similar behavior as the potential (45).

**B. Phantom power-law**

Another interesting solution is the phantom power-law, that gives an EoS below the cosmological constant which is not ruled out by current astrophysical observations, but leads to future Big Rip singularity. Assuming the following functions

\[ f(\phi) = t_s - t_0 e^{\phi/\phi_0}, \quad g(t) = -p \ln \left( \frac{t_s - t}{t_0} \right) \]  

(47)

which give

\[ H = \frac{p}{t_s - t}, \quad \phi = \phi_0 \ln \left( \frac{t_s - t}{t_0} \right) \]  

(48)

Replacing in the GB coupling (16) we find

\[ \eta(\phi) = \left[ c_0' (p, \xi) + c_1' (p, \xi) \phi + c_2' (p, \xi) \phi^2 \right] e^{2\phi/\phi_0}, \]  

(49)

where

\[ c_0' (p, \xi) = \frac{2p(p - 1)^2 - ((3\xi - 1)p^2 + 2p + \xi - 1)\kappa^2 \phi_0^2}{16p^2(p - 1)^3} \]

\[ c_1' (p, \xi) = \frac{(3p - 1)\kappa^2 \phi_0}{8p^2(p - 1)^2} \]

\[ c_2' (p, \xi) = -\frac{\xi \kappa^2}{8p(p - 1)} \]

and the potential from (17) takes the form

\[ V(\phi) = \left[ d_0' (p, \xi) + d_1' (p, \xi) \phi + d_2' (p, \xi) \phi^2 \right] e^{-2\phi/\phi_0}, \]  

(50)

where

\[ d_0' (p, \phi) = 6p^2(p + 1)(p - 1)^2 + (5p^3 - 3(8\xi + 3)p^2 + 3p + 1)\kappa^2 \phi_0^2 \]

\[ 2(p - 1)^3 \]

\[ d_1' (p, \xi) = \frac{12p^2\xi \kappa^2 \phi_0}{(p - 1)^2} \]

\[ d_2' (p, \xi) = -\frac{3(p + 1)p^2\xi \kappa^2}{p - 1} \]

According to (48), \( \phi \to -\infty \) at \( t \to t_s \) and the scalar potential (50) becomes infinity giving rise to the Big Rip singularity. This phantom behavior can also be obtained with the following functions

\[ t = f(\phi) = t_s - t_0 \frac{\phi}{\phi_0}, \quad g(t) = -p \ln \left( \frac{t_s - t}{t_0} \right) \]  

(51)

which give the Gauss-Bonnet coupling

\[ \eta(\phi) = -\frac{t_0^2}{8p^2 \kappa^2 \phi_0^2} \left( -\frac{p \phi^2}{p - 1} + \frac{(2(2p + 1)\xi - 1)\kappa^2 \phi^4}{4(p + 1)} \right) \]  

(52)

and the scalar potential

\[ V(\phi) = \frac{1}{2(p^2 - 1)t_0^2 \kappa^2 \phi_0^2} \left[ 6p^2(p + 1)^2 \phi_0^2 - (p - 1)((6p(p + 3)\xi - 5)p + 1)\kappa^2 \phi_0^2 \phi^2 \right] \]  

(53)

This potential also grows toward infinity since \( \phi \to 0 \) at \( t \to t_s \). The expressions for the potentials (45) and (49) show a run-away behavior (i.e. \( V \to 0 \) at \( \phi \to \infty \)) which is important in the phenomenology of dark energy since it reflects the scaling behavior of the model. The potentials like (43) and (50) which contain combination of exponential and power-law terms can be present in the low energy limit of M-theory as proposed in [59, 60].
it was shown that simple corrections to pure exponential potential produce interesting quintessence accelerating solutions. In the present model (1) these corrections allow not only quintessence but also phantom scenarios (at least of the power-law type). Note that from (42), (43), (49), and (50) follows that when the non-minimal coupling disappears, then only the free term \( c_0, \) \( d_0, \) \( c'_0 \) and \( \xi' \) survive in the corresponding expressions, and the GB coupling and potential become pure exponentials for quintessence and phantom power-law.

C. The de Sitter solution

The model (1) (with \( \mathcal{L}_m = 0 \)) contains de Sitter solution with varying scalar field as we show in the following two examples. Taking the functions

\[
f(\phi) = t_0 \frac{\phi}{\phi_0}, \quad g(t) = H_0 t
\]

that lead to

\[
H = H_0, \quad \phi = \phi_0 \frac{t}{t_0}
\]

we find the Gauss-Bonnet coupling and the potential as

\[
\eta(\phi) = -\frac{(\phi_0 + \xi H_0 t_0 \phi) \phi}{8t_0 H_0^2}
\]

\[
V(\phi) = \frac{5\phi_0^2}{2t_0^2} + 3H_0^2 \left( \frac{1}{2} - \xi \phi^2 \right)
\]

The following functions also give the de Sitter solution

\[
t = f(\phi) = -t_0 \ln \left( \frac{\phi}{\phi_0} \right), \quad g(t) = H_0 t
\]

from where \( \phi = \phi_0 e^{-t/t_0} \), which lead to the Gauss-Bonnet coupling

\[
\eta(\phi) = \frac{(1 - 2(H_0 t_0 + 2)\xi) \phi^2}{16H_0^2 (H_0 t_0 + 2)}
\]

and the expression for the potential (17) becomes

\[
V(\phi) = \frac{3H_0^2}{\kappa^2} - \frac{(6H_0 t_0 (H_0 t_0 + 2) \xi - 5)H_0 t_0 + 2) \phi^2}{2(\xi H_0 + 2)^2 t_0^2}
\]

Note that in absence of potential and for the asymptotic case of constant \( \phi \) there is not de Sitter solution.

D. Little Rip solution

This type of solutions represent an alternative to Big Rip [61, 62] where the dark energy density increases with time but without facing a finite time future singularity. In Little Rip solutions the equation of state parameter \( w < -1 \) (or \( H > 0 \)) and causes the same effect of dissociation of matter in the future as the Big Rip solutions, but the scale factor, the density and pressure remain finite at finite time. Let’s consider the following scenario

\[
H = H_0 e^{ht}, \quad \phi = \phi_0 e^{ht}
\]

From where it is seen that \( f(\phi) = H_0 \frac{1}{t} \ln \left( \frac{\phi}{\phi_0} \right) \) y \( g(t) = H_0 e^{ht} \). If we replace these functions in (16) and (17) in absence of matter one obtains

\[
\eta(\phi) = \frac{h^2(1 - 4\xi) \phi_0^4}{16H_0^2 \phi^2} + \frac{hH_0(1 - 4\xi) \phi_0^3}{8H_0^2 \phi^3} + \frac{\phi_0^2}{8H_0^2 \kappa^2 \phi^2
\]

\[
V(\phi) = m_1 \phi + m_2 \phi^2 + m_3 \phi^3 + m_4 \phi^4
\]

where

\[
m_1 = \frac{1}{2} \left( \frac{6h^2(1 - 4\xi) \phi_0}{H_0} + \frac{12hH_0}{\kappa^2 \phi_0} \right), \quad m_2 = \frac{1}{2} \left( h^2(5 - 24\xi) + \frac{6H_0^2}{\kappa^2 \phi_0^2} \right), \quad m_3 = -\frac{6hH_0 \xi}{\phi_0}, \quad m_4 = -\frac{3H_0^2 \xi}{\phi_0^2}
\]

Note that for times \( t < t_s/2 \) the universe is in the quintessence phase, and enters the phantom phase for times \( t > t_s/2 \). The Big Rip singularity occurs at \( t = t_s \). The general expressions for \( \eta \) and \( V \) for arbitrary \( p \) depend on hypergeometric functions and are too large. Here we limit ourselves to the special case \( p = 2 \) where the expressions for the GB coupling and potential take the form

\[
H = p \left( \frac{1}{t} + \frac{1}{t_s - t} \right), \quad \phi = \frac{\phi_0}{t_0} t
\]

E. Solutions with quintessence and phantom phases

Another interesting scenario that allows the integration in Eqs. (16) and (17) presents quintessence and phantom phases and comes from the functions \( f(\phi) = \frac{t_0 t}{\phi_0} \) and \( g(t) = p \ln \left( \frac{t}{t_s - t} \right) \), which give

\[
H = p \left( \frac{1}{t} + \frac{1}{t_s - t} \right), \quad \phi = \frac{\phi_0}{t_0} t
\]
\[ \eta(\phi) = -\frac{1}{9600\kappa^2 t_0^2 \phi_0^3} \left[ t_0^2 \phi^2 \left( 50\kappa^2(2\xi - 1)t_0^2 \phi^4 + 120\kappa^2(4\xi + 1)t_0t_s \phi^3 \phi_0 \ln(\phi) - 8t_0t_s \phi \phi_0 \left( 3\kappa^2(4\xi + 1)\phi^2 - 50 \right) + 25t_s^2 \phi_0^2 \left( 3\kappa^2(6\xi + 1)\phi^2 - 8 \right) \right) \right] \] 

(64)

\[ V(\phi) = -\frac{1}{2\kappa^2 t_0^2 \phi^2 (t_0 \phi - t_s \phi_0)^3} \left[ \phi_0^2 \left( \kappa^2 t_0^3 \phi^5 - 15\kappa^2 t_0^2 t_s \phi^4 \phi_0 + 24\kappa^2(4\xi + 1)t_0t_s^2 \phi^3 \phi_0^2 \ln(\phi) + 3t_0t_s \phi \phi_0 \left( \kappa^2(24\xi + 1)\phi^2 + 8 \right) + t_s^3 \phi_0^3 \left( \kappa^2(24\xi + 11)\phi^2 + 8 \right) \right) \right] \] 

(65)

Note that although the GB coupling (64) remains finite, the potential (65) becomes infinite at \( t \rightarrow t_s (\phi \rightarrow \phi_0 t_s / t_0) \).

V. SOLUTIONS WITH MATTER COMPONENT

In this case we consider the general equations (16) and (17) with \( g_0 \neq 0 \). Below it is shown that even with matter content, the power-law expansion scenarios are solutions. These solutions are important when one of the components is dominating over the other.

A. Quintessential solutions

We consider power-law solutions of the form

\[ H = \frac{p}{t}, \quad \phi = \phi_0 \ln \left( \frac{t}{t_0} \right) \] 

(66)

which lead to \( f(\phi) = t_0 e^{\phi/\phi_0} y g(t) = p \ln \left( \frac{t}{t_0} \right) \). By replacing in (16), we find the GB coupling as

\[ d_0 = \frac{6p^2(-1 + p)(1 + p)^2 + \kappa^2 \phi_0^2(-1 + p(3 + p(9 + 5p + 24\xi))}{2(1 + p)^3}, \quad d_1 = \frac{12\xi p^2 \kappa^2 \phi_0}{(1 + p)^2} \]

\[ d_2 = \frac{-3\xi p^2 \kappa^2(-1 + p)}{1 + p}, \quad B = \frac{g_0 \kappa^2 t_0^2(1 - p)}{p(3w + 4) - 1} \]

Note that as the scalar field evolves according to (67), all the exponential terms in the potential (68) decrease

\[ \bar{\eta} = e^{2\phi/\phi_0} \left[ c_0 + c_1 \phi + c_2 \phi^2 + Ac^{2\phi/\phi_0} e^{-3p(1+w)\phi/\phi_0} \right] \]

(67)

where \( \bar{\eta} = \frac{\xi^2}{t_0^2} \eta \). The constants \( c_0, c_1, c_2 \) \( y \) \( A \) are given by

\[ c_0 = \frac{2p(1 + p)^2 - \kappa^2 \phi_0^2(1 - \xi + 2p + p^2 - 3p^2 \xi)}{16p^2(1 + p)^3} \]

\[ c_1 = -\frac{\xi \kappa^2 \phi_0(1 + 3p)}{8p^2(1 + p)^2} \]

\[ c_2 = -\frac{\xi \kappa^2}{8p(1 + p)} \]

\[ A = \frac{g_0 \kappa^2 t_0^2(w + 1)}{8p^2(3p(w + 1) - 4(p(3w + 4) - 1)} \]

By using the functions \( f(\phi) = t_0 e^{\phi/\phi_0} y g(t) = p \ln \left( \frac{t}{t_0} \right) \) in the Eq. (17) one finds

\[ \bar{V} = e^{-2\phi/\phi_0}(d_0 + d_1 \phi + d_2 \phi^2) + Be^{-3p(1+w)\phi/\phi_0} \]

(68)

where \( \bar{V} = \kappa^2 t_0^2 V \) and the constants \( d_0, d_1, d_2 \) \( y \) \( B \) are given by

(\( w > -1 \)) and the potential takes a run-away shape. The
scaling behavior of the DE component is clear from the potential (68) since the first term is the same potential for the power-law in absence of matter (45) (which gives \( \rho \propto t^{-2} \)) and the correction due to the presence of matter also contributes to the density a term \( \propto t^{-2} \).

**B. Phantom solutions**

Another interesting cosmology is described by

\[
H = \frac{p}{t_s - t}, \quad \phi = \phi_0 \ln \left( \frac{t_s - t}{t_0} \right) \tag{69}
\]

From which follows that \( f(\phi) = t_s - t_0 e^{\frac{\phi}{\phi_0}} \) y \( g(t) = -p \ln \left( \frac{t_s - t}{t_0} \right) \). This solution describes phantom evolution with \( w < -1 \) and finite time Big Rip future singularity at \( t = t_s \).

By replacing the functions (69) in the GB coupling (16) it is found that

\[
d_0' = \frac{6p^2(1 + p)(-1 + p)^2 + \kappa^2 \phi_0^2(1 + 3p - 9p^2 + 5p^3 - 24p^2 \xi)}{2(-1 + p)^3}, \quad d_1' = \frac{12p^2 \kappa^2 \phi_0 \xi}{(-1 + p)^2}
\]

\[
d_2' = -\frac{3p^2(1 + p)\kappa^2 \xi}{-1 + p}, \quad d_2' = \frac{g_0 \kappa^2 t_0^2(1 + p)}{p(3w + 4) + 1}
\]

From (69) follows that as \( t \to t_s \) the scalar field \( \phi \) tends to \(-\infty\) and the scalar potential (71) undergoes an exponential growth \( (w < -1) \), evolving towards the Big Rip singularity at \( t \to t_s \). It is interesting to note that even in the presence of matter (minimally coupled as in model (1)) the model may reproduce quintessence or phantom evolution, leading to an effective dark energy universe.

**VI. CONCLUSION**

It is well known that different couplings of scalar field to curvature appear in a variety of contexts ranging from the quantization of matter fields on curved background to multidimensional theories like string or M-theory. In this regard, it is natural to wonder whether the scalar-tensor couplings predicted by fundamental theories may become important at current low-curvature universe. In this paper we have considered a model of scalar field with non-minimal and GB couplings in the FRW background, as a model of dark energy. In the model without potential and under appropriate restriction of the GB coupling (given by (23) with \( g_1 = 1/(8\kappa^2) \)), we have found exact solutions that give appropriate description of the accelerated expansion. First under the restriction (33) the model describes quintessence dark energy, and its behavior is determined by the initial value \( \phi_0 \) and the non-minimal coupling \( \xi \). Some evolutionary scenarios are shown in Fig. 3, where some of them are very close to the cosmological constant. For the more general case it was shown that the model allows phantom DE evolution without facing Big Rip or any other singularity. We have found that the equation of state has different asymptotic behaviors depending on the couplings of the model, but in all cases is consistent with current observations on DE EOS. Thus for instance, solutions for positive \( \lambda = 1/8, 1/16 \)
(see Fig. 3) describe an universe with EOS currently \( w_0 = -1 \) and undergoing the transition from phantom to quintessence phase. But changing the sign, i.e. taking \( \lambda = -1/8, -1/16 \) the transition goes in opposite direction, where the universe evolves towards the phantom phase. We can deduce from the equation (39) that the current phase \( (x = 0) \) of the EOS depends on the product \( \gamma (\kappa \phi_0)^2 \): if \( \gamma (\kappa \phi_0)^2 > -6 \), then the EOS is currently \( w_0 > -1 \) (quintessence phase), if \( \gamma (\kappa \phi_0)^2 < -6 \) then \( w_0 < -1 \) (phantom phase). The case depicted in Fig. 3 corresponds to \( \gamma (\kappa \phi_0)^2 = -6 \), where the DE universe is currently passing through the barrier of the cosmological constant. The model also gives appropriate description of DE for small values of the non-minimal coupling \( \xi \) as shown in Figs. 4 and 5, which describe scenarios with phantom phase, with transition from phantom to quintessence phase (Fig. 4) and from quintessence to phantom phase (Fig. 5) in different cosmological epochs. In all cases we have found that the model covers a variety of DE scenarios, all of them in the range of the measurements made by the different collaborations.

We also considered an approach that allows in principle to reconstruct the potential an the GB coupling for arbitrary given cosmological scenarios [48]. We showed explicit examples of reconstruction for quintessence and phantom power-law solutions, where the obtained potentials are of exponential form with polynomial factor. These type of potentials were proposed in [59, 60] as coming from low-energy limit of higher dimensional theories (after compactification of extra dimensions), and which present attractive features for description of realistic cosmologies. The fact that the potential was reconstructed from power-law solutions, indicates that if we start from the model (1) with GB coupling and potential given by (42) and (43) respectively, then the dynamics of this model on the FRW background gives rise to scaling solutions which play an important role in quintessence scenarios [8]. The polynomial factor in the potential and GB coupling disappears in absence of the non-minimal coupling \( (\xi = 0) \) as follows from expressions (42), (43), (49) and (50), leading to pure exponential GB couplings and potentials, which are typical of string-inspired gravity models.

The model could also be reconstructed for a Little Rip solution where the Hubble parameter increases exponentially and the scalar potential becomes a fourth-order polynomial. A quintom scenario with quintessence and phantom phases was also reconstructed for the Hubble parameter (63), which led to the GB coupling (64) and potential (65). It is worthwhile to emphasize that the phantom scenario could be realized without introducing the ghost scalar field, which is quite attractive for a viable model of dark energy. For the de Sitter solution we have found that both the potential and the GB coupling depend on the square of the field.

Resuming, the non-minimal and GB couplings allow exact solutions that give rise to interesting cosmological scenarios describing the DE in a manner consistent with current astrophysical observations. These solutions include phantom expansion without singularities and transitions between quintessence and phantom phases. It was also demonstrated that in principle any given late-time cosmological solution relevant to current observations (including quintessence, phantom, quintom, de Sitter, Little Rip) may be reconstructed by scalar-tensor model with GB and non-minimal coupling. The reconstructed potential for power-law quintessence solutions has been considered previously as coming from higher dimensional gravity theories. All these facts enable us to conclude that the combination of GB and non-minimal couplings gives a good explanation of the dynamics of the late time universe, and could play an important role in revealing the nature of the DE.
