We present the formalism for the decay of dynamically generated scalar mesons with open- or hidden-charm and give results for the decay of $D_{s0}^*(2317)$ to $\gamma D_s^*$ plus that of a hidden charm scalar meson state predicted by the theory around 3700 MeV decaying into $\gamma J/\psi$.

I. INTRODUCTION

The discovery of charmed scalar meson resonances at Babar, Belle and CLEO [1, 2, 3, 4] has stimulated a fruitful line of research, suggesting that their structure is much richer than what one might guess assuming the $q\bar{q}$ picture, which has proved quite successful in other areas [5]. Some authors have suggested a $qqqq$ structure [6, 7] or mixing between the usual $qq$ structure and four quark [8]. Also there have been suggestions that these states might be molecular states of the pseudoscalar mesons $s\bar{s}^{(*)}$ [9, 10, 11, 12, 13]. Similar to this latter works, but with subtle differences that we shall discuss later on, are the pictures where these states appear as dynamically generated in the context of unitarized chiral perturbation theory [14, 15, 16, 17]. The works in [14, 15, 16] rely upon Lagrangians based on heavy quark symmetry, while the one of [17] starts from an extension of the $SU(3)$ chiral Lagrangian to $SU(4)$ which is largely broken due to the implicit vector meson exchange characterizing the Weinberg-Tomozawa term of the chiral Lagrangian [18]. Because of this, the terms of the Lagrangian used in [17] are suppressed by the ratio of the light to heavy mass squared of the vector mesons. $SU(4)$ Lagrangians with covariant derivatives adapted to include weak interactions are used in [10]. The Lagrangian in [17] contains the Lagrangian used in [14, 16], which is suited for the study of open-charm resonances like the $D_{s0}^*(2317)$, but it also contains other terms which allow to study the hidden-charm states. The comparison of the results using this Lagrangian with another one using a chiral symmetry breaking extension to $SU(N)$ of the $SU(3)$ results [20] allows to have an idea of the uncertainties in the results. The stability of the $D_{s0}^*(2317)$ was confirmed, while the $X(3700)$ state could sometimes become a cusp instead of a bound state, but experimentally it would lead to a bump in the mass distributions in any case. Hence one is confident that the new state should also be found.

The radiative decay of resonances has been usually suggested as a test for their nature [21, 22]. In the present case, we are interested in the decay $D_{s0}^*(2317) \rightarrow D_s^*\gamma$ and $X(3700) \rightarrow \gamma J/\psi$. The first of these decays has been evaluated assuming varied structures for the resonance, within quark models, vector meson dominance, light cone QCD sum rules, etc [23, 24, 21, 26, 27, 28, 29, 30, 31, 32] and more recently from the point of view of the $D_{s0}^*(2317)$ as a molecular state [33]. The $X(3700)$ has also been predicted in [34] as a molecular state assuming a reasonable interaction Lagrangian between the $D$ and $D^*$ states. The radiative decay of this predicted state is reported here for the first time.

II. FORMULATION FOR THE RADIATIVE DECAY

In a picture of the scalar mesons as dynamically generated one needs to couple the photon to the meson components of the coupled channels. Here the reactions studied are

$$D_{s0}^*(2317) \rightarrow \gamma D_s^*$$

$$X(3700) \rightarrow \gamma J/\psi$$

and the technical way to evaluate them is considering the loop diagrams of Fig. 4.

These are the same diagrams used in the evaluation of the radiative decay of the $D_{s0}^*(2317)$ as a $DK$ molecule in [33]. The differences are that here we do not need the wave function of the $D_{s0}^*(2317)$, we only need the couplings of the resonance to the $PP$ channels which are obtained in the study of these resonances as dynamically generated in [17]. Another difference is that we have more channels than $DK$, and this has some numerical effects in the results because of cancellations of terms in the most important channels $D^+K^0, D^0K^+$. Finally, although it provides a small contribution in [33], there is a term where the photon couples to the $D_s^*$: This term involves a transition $D_{s0}^*(2317) \rightarrow D_s^*$ which is allowed for a virtual $D_s^*$ as it would be the case here. Such terms mix the longitudinal part of the vector meson propagator

\*E-mail: daniel.gamermann@ific.uv.es

‡E-mail: oset@ific.uv.es
with the scalar meson. However, in order to prevent the appearance of a pole of a scalar in the vector meson propagator, in a covariant formalism like the one we use, this transition amplitude must vanish for \( P^2 = m_S^2 \), with \( P \) and \( m_S \) the total momentum and the mass of the scalar meson, respectively [33, 30]. This is discussed in a related work on the radiative decay of axial vector mesons [37], but we address the problem in detail in appendix A. There is also a diagram with the photon attached to the scalar resonance (for charged states), which is shown to vanish in the amplitude in [33] due to the lorentz condition of the vector meson.

The two diagrams discussed above, together with those considered in figure 1, provide a set of gauge invariant terms, as shown explicitly in [33]. The two terms with the photon coupling to the external particles in the loop diagram play a role in the gauge invariant test of the theory, as shown in [33], but they vanish in the radiative decay amplitude, as we show in appendix A.

The procedure to evaluate the radiative decay followed here for the dynamically generated scalar resonances has been tested with success in the decays \( \phi \to f_0(980) \gamma \) and \( \phi \to a_0(980) \gamma \) [33, 32, 31] with the \( f_0 \) and \( a_0 \) resonances dynamically generated from the interaction of the lowest order meson-meson chiral Lagrangian [41]. The present reaction is the time reversal reaction, in the charmed sector, of the radiative \( \phi \) decay into a scalar and a photon. The same ideas presented here are used in the study of the radiative decay of the \( f_0(980) \) and \( a_0(980) \), as dynamically generated resonances, into \( \gamma \rho \) and \( \gamma \omega \) in [22].

The channels to which the \( D_{s0}^*(2317) \) and the \( X(3700) \) resonances have appreciable couplings in [17] are the following:

- \( D_{s0}^*(2317) : D^+ K^0, D^0 K^+, D_s^+ \eta, D_s^+ \eta_c \)
- \( X(3700) : D^+ D^-, D^0 D^0, D_s^+ D_s^- \)

We shall demonstrate that, using arguments of gauge invariance, we can overcome the evaluation of the diagram c) of Fig 1 and, as a consequence, we must only evaluate the diagrams of Fig 2 for the \( D_{s0}^*(2317) \) and of Fig 3 for the \( X(3700) \).

Let us proceed to the explicit evaluation of the diagrams. The amplitude of the diagram of Fig 2 a) is readily evaluated as:

\[
- iT = \int \frac{d^4q}{(2\pi)^4} \left( -i \right) g_{D_{s0}^*(2317)\rightarrow \gamma D_s^*} \nonumber \times \int \frac{i}{(q+K)^2 - m_1^2 + i\epsilon} \times \frac{i}{(Q-q)^2 - m_2^2 + i\epsilon} \times (-i)\epsilon_{\nu}^{(\gamma)}(q+q+K)\gamma^\nu \times (+i) \frac{1}{\sqrt{2}} \frac{M_V G_F}{16\pi J_D^2} \epsilon_{\mu}(D_s^*) (q-Q+q)^\mu \lambda^\nu \tag{1}
\]

where \( m_1 \) and \( m_2 \) are the masses of the upper and lower pseudoscalar mesons in the loop diagram, \( \epsilon_{\mu}^Q \) is the
the amplitude of eq. (1) is simplified and we obtain:

\[ \epsilon_\mu(D^{*+})Q^\mu = 0 \]
\[ \epsilon_\nu(\gamma)K^\nu = 0, \]

the amplitude of eq. (1) is simplified and we obtain: charge \((e > 0)\) of the upper pseudoscalar meson, \(M_V\) the mass of the vector meson and \(G_V\) the VPP coupling \((G_V = 55 \text{ MeV})\). The constant \(g_{D^{*0}\to D^+ K^0}\) provides the coupling of the resonance to the \(D^+ K^0\). In Table 1 we show the calculated couplings for the poles from [17] located at 2317.25 MeV and \((3718.93-i0.06)\) MeV. For this last one we have neglected its imaginary part.

The coupling of the vector meson to the pseudoscalars is obtained from the \(SU(4)\) generalization (see [17]) of the ordinary \(SU(3)\) Lagrangian.

\[
\mathcal{L}_{PPV} = -\frac{ig}{\sqrt{2}} Tr ([\partial_\mu \phi, \phi] V^\mu) \tag{2}
\]

with \(g = -M_V G_V / f^2\) and the \(SU(4)\) matrices \(\phi\) and \(V^\mu\) given by

\[
\begin{align*}
\phi &= \begin{pmatrix}
\pi^0 & \pi^- & K^+ & \bar{D}^0 \\
\pi^- & \pi^+ & K^0 & D^-
\end{pmatrix} \\
V^\mu &= \begin{pmatrix}
\rho^+ & K^+ & \bar{D}^{*0} \\
\rho^- & K^0 & D^* \\
\rho^{*+} & \bar{K}^* & D^{*0} \\
\rho^{*-} & K^* & D^{*-}
\end{pmatrix}
\end{align*}
\]

In eq. (1) we have chosen to substitute \(f^2\) in the denominator by \(f_\pi f_D\) following the prescription in [17] of associating \(f_\pi\) (the pion decay constant, \(f_\pi = 93 \text{ MeV}\)) to the light pseudoscalars and \(f_D = 165 \text{ MeV}\) to the charmed pseudoscalars.

All the other diagrams are easily obtained by changing the couplings of the resonance to the channel and the constant \(\lambda_V\) to account for the different VPP vertices. The different values of \(\lambda_V\) are given in Table II.

By using the Lorentz condition for the photon and the vector meson,

\[
T = -i g_{D^{*0}\to D^+ K^0} \epsilon_\mu(D^{*}) \epsilon_\nu(\gamma) \frac{4 M_V G_V}{\sqrt{2} f_\pi f_D} \epsilon_\mu(D^{*}) \epsilon_\nu(\gamma)
\]

\[
\int \frac{d^4q}{(2\pi)^4} \frac{1}{(q + K)^2 - m_1^2 + i\epsilon} \frac{1}{q^2 - m_1^2 + i\epsilon}
\]

\[
\int \frac{d^4q}{(Q^2 - m_1^2 + i\epsilon)^2} \frac{1}{q^\mu q^\nu}
\]

Upon integration of the \(q\) variable one has the expression:

\[
T = T_{\mu\nu} \epsilon_\mu(V) \epsilon_\nu(\gamma)
\]

\[ T^{\mu\nu} = ag^{\mu\nu} + bQ^{\mu}Q^{\nu} + cQ^{\mu}K^{\nu} + dK^{\mu}Q^{\nu} + eK^{\mu}K^{\nu} \quad (9) \]

The Lorentz condition of eqs. (5) and (6) removes the $K^{\mu}K^{\nu}$ term because it is finite and only one term is needed in the evaluation. We choose to evaluate the $K^{\mu}K^{\nu}$ term such that only one term is needed in the evaluation. We write:

\[ a = -(dQ.K) \quad (10) \]

such that only one term is needed in the evaluation. We choose to evaluate the $d$ term because it is finite and only comes from the diagrams of figs. 2 and 3. The procedure outlined here has been used before in the evaluation of the $\phi \rightarrow \gamma K^{0}\bar{K}^{0}$ decay [12].

The amplitude $T$ is now easily written as:

\[ T = -d(Q.K g^{\mu\nu} - K^{\mu}Q^{\nu})\epsilon_{\mu}(V)\epsilon_{\nu}(\gamma) \quad (11) \]

The evaluation of $d$ is straightforward following the Feynman formalism. We write:

\[ \frac{1}{abc} = 2 \int_{0}^{1} dx \int_{0}^{x} dy \frac{1}{(a + (b - a)x + (c - b)y)^{3}} \quad (12) \]

with:

\[ a = (Q - q)^{2} - m_{2}^{2} \quad (13) \]
\[ b = q^{2} - m_{1}^{2} \quad (14) \]
\[ c = (q + k)^{2} - m_{1}^{2} \quad (15) \]

Upon a transformation $q = q' + Q(1 - x) - Ky$ we are left with the integral:

\[ \int \frac{d^{4}q'}{(2\pi)^{4}} \frac{(q' + Q(1 - x) - Ky)^{\mu}}{(q'^{2} + s + i\epsilon)^{3}} \times \left( q' + Q(1 - x) - Ky \right)^{\nu} \quad (16) \]

with $s = Q^{2}x(1 - x) + 2Q.K(1 - x)y - m_{2}^{2} + (m_{2}^{2} - m_{1}^{2})x$, which shows that the contribution to the $d$ term comes from:

\[ \int \frac{d^{4}q'}{(2\pi)^{4}} \frac{K^{\mu}Q^{\nu}(1 - x)y}{(q'^{2} + s + i\epsilon)^{3}} \quad (17) \]

where two powers of $q'$ have disappeared from the integral and hence it is convergent. The $q'$ integral is also readily done following the Feynman formalism:

\[ \int \frac{d^{4}q'}{(2\pi)^{4}} \frac{1}{(q'^{2} + s + i\epsilon)^{3}} = \frac{i\pi^{2}}{(2\pi)^{4}} \frac{1}{2} \frac{1}{s + i\epsilon} \quad (18) \]

and the $d$ coefficient is readily obtained as:

\[ d = -9_{D^{*0}(2317)\rightarrow P\bar{P}Q} \lambda_{V} \frac{M_{V}G_{V}}{f_{\pi}f_{D}} \frac{\sqrt{2}}{8\pi^{2}} \times \int_{0}^{1} dx \int_{0}^{x} dy \frac{(1 - x)y}{s + i\epsilon} \quad (19) \]

As mentioned above, one can see, following the same procedure, that the diagram in fig. 1(c) only contributes to the $ag^{\mu\nu}$ term of eq. (9) and thus we do not need to calculate it.

The finiteness of the results is also noted in [33] where the wave function is governed by a range parameter $\Lambda$, and the results remain finite in the limit of $\Lambda \rightarrow \infty$.

One must sum coherently the contribution of each term of the diagrams in fig. 2 to the $d$ coefficient and then the radiative decay width is given finally by:

\[ \Gamma = \frac{1}{8\pi m_{D^{*0}(2317)}} |\bar{K}|2(K.Q)^{2}|d|^{2} \quad (20) \]

where $|\bar{K}|$ is photon three momentum in the rest frame of the $D^{*0}(2317)$.

The decay of the $X(3700)$ proceeds identically through the same lines using the appropriate couplings and masses in the diagrams of fig. 3.
TABLE III: Results

| Diagram | $d$ [fm] | $\Gamma$ [KeV] |

III. RESULTS

In Table III we show the results for the $d$ coefficient from each term in fig. 2.

As we can see, the largest contribution comes from the $K^+D^0$ intermediate state. The $D^+K^0$ is smaller than the $K^+D^0$ since it involves two heavy pseudoscalar propagators instead of two light ones. Next and weaker than the others is the contribution of the $D^+_s\eta$ channel, and finally the $D^+_s\eta_c$ channel provides a negligible contribution.

Note that the contribution from the two charge partners in the isospin $I=0$ $DK$ channel is destructive. Had the $D^*_{s0}(2317)$ been an isospin $I=1$ resonance, the relative couplings to the two channels would have been opposite, making thus a constructive interference and we would have obtained a width of 4 KeV instead of 0.488 KeV, a factor eight times bigger. Furthermore, because of the destructive interference, the effect of the $D^+_s\eta$ channel, which is quite small by itself, becomes relevant. Indeed, if we neglect the channels with the $D^+_s$ meson, the width obtained is $\Gamma =0.872$ KeV a factor 1.8 times bigger than when one takes them into account. Then, one can see that the consideration of all the coupled channels of the approach is quite relevant, which introduces one novel element with respect to the ordinary molecular picture [33] where only the dominant $KD$ channel is taken into account.

The results for the $X(3700)$ radiative decay are shown in Table IV. We see that this radiative decay is considerably larger than for the $D^*_{s0}(2317)$. In this case all the terms add constructively.

Next we perform an analysis of the uncertainties in the results. The fact that we have obtained a very small width, because of strong cancellations, indicates that it should be rather sensitive to uncertainties in the input used for the evaluation.

To evaluate the uncertainties we will follow the same procedure used in [17]. We will take a random generated ensemble of sets for the input parameters within a physical allowed range and calculate the radiative decay for each set of parameters in the ensemble. The uncertainties in the results are then given by the standard deviation from the mean value calculated:

$$\sigma^2 = \frac{\sum_{i=1}^{N}(\Gamma - \Gamma_i)^2}{N-1}$$

$$\bar{\Gamma} = \frac{1}{N} \sum_{i=1}^{N} \Gamma_i$$

Since the radiative decay of the $D^*_{s0}(2317)$ is very small and the uncertainties are of the same order of magnitude, we will separately calculate the standard deviation above and under the mean value. The parameters will be generated within the ranges [17]:

$$M_V = 2060 \pm 52 \text{ MeV}$$
$$f_D = 182 \pm 36 \text{ MeV}$$
$$f_{\pi} = 100 \pm 15 \text{ MeV}$$
$$m_{D^*_{s0}(2317)} = 2316 \pm 39 \text{ MeV}$$
$$g_{D^*_{s0}(2317)}DK = -6420 \pm 1790 \text{ MeV}$$
$$g_{D^*_{s0}(2317)}D_s\pi = 5250 \pm 1430 \text{ MeV}$$
$$g_{D^*_{s0}(2317)}D_s\eta_c = 1450 \pm 470 \text{ MeV}$$
$$m_X(3700) = 3698 \pm 35 \text{ MeV}$$
$$g_X(3700)D^+D^- = 8089 \pm 3125 \text{ MeV}$$
$$g_X(3700)D^+_sD^-_s = 5339 \pm 2100 \text{ MeV}$$

When we do the exercise for $N=500$ randomly generated parameter sets, we obtain

$$\Gamma_{D^*_{s0}(2317)} = 0.475^{+0.831}_{-0.290} \text{ KeV}$$

and

$$\Gamma_X(3700) = 18.45 \pm 13.00 \text{ KeV}$$

It is instructive to compare our results with those of [33] for the $D^*_{s0}(2317)$. They are rather similar. In [33] the results vary from 0.47 KeV in some approximations to 1.41 KeV in other approximations. Our uncertainties stem from different sources, couplings, masses, etc, but the range of values obtained is very similar. A comparison of these results with those of different quark models is made in [33] and we address the reader to Table III of this reference. The results obtained with the present picture are in general smaller than those obtained in quark models or other pictures. The destructive interference between the two components of the main isospin channel is the main reason for it. Precise experiments on this rate should help us understand better the nature of
We found very different results for the two states. While the predicted hidden-charm state X(3700), not yet observed.

Concerning the X(3700) state and its radiative decay, the large width obtained for the decay into $\gamma J/\psi$ should make its observation easy, in principle, and we also re- 

IV. CONCLUSIONS

We have presented here the evaluation of the radiative decay of the open and hidden-charm scalar mesons which are dynamically generated from the interaction of two pseudoscalar mesons. The calculations have been done for the $D_s^{*0}(2317)$ open-charm scalar state and for the predicted hidden-charm state X(3700), not yet observed. We found very different results for the two states. While the $D_s^{*0}(2317)$ decay into $\gamma D_s^*$ has a width of around 0.5 KeV, the X(3700) has a width into $\gamma J/\psi$ of the order of 20 KeV, a factor forty times bigger. One of the reasons, but not the only one, was the large cancellation between the two charge partners of the isospin component of the $DK$ I=0 state. With the obvious similarities, we also found subtle differences between the $DK$ molecular picture for the $D_s^{*0}(2317)$ state and the dynamically generated picture. The latter one, including more channels than just the $DK$, showed sensitive effects from the $D_s\eta$ state, particularly because of the large cancellation found between the dominant $D^+ K^0$ and $K^+ D^0$ states. Yet, within the theoretical uncertainties, the final result obtained in the two pictures are rather similar.

We also presented a different technical way to evaluate the amplitudes which makes the formalism simpler and shows immediately the finiteness of the results using arguments of gauge invariance.

Concerning the X(3700) state and its radiative decay, the large width obtained for the decay into $\gamma J/\psi$ should make its observation easy, in principle, and we also re-called that the predictions on this state were rather solid so that it should be observed as a bound state or a strong cusp, in both of which cases the radiative decay could be investigated. The observation of this state with its relatively large radiative width would provide a boost to the idea of the low energy scalar mesons with open-charm and some particular hidden-charm scalar states as dynamically generated resonances.

APPENDIX A: PHOTON COUPLING TO EXTERNAL LINES

In addition to the diagrams considered in figure 1, one should also include two extra diagrams, for the case of the decay of charged particles, where the photon couples to the external lines, see figure 1.

These two diagrams are explicitly considered in 3.3 and shown to be relevant in the test of gauge invariance. However, we show here that they vanish in the amplitude for on-shell $D_s^{*0}(2317)$ and $D_s^*$.

To prove this we first evaluate the loop function in figure 4

$$ J(P^2)P^\mu\epsilon_\mu(D_s^*) = i \int \frac{d^4q}{(2\pi)^4} \frac{g_{\gamma D_s^* DK}}{(P+q)^2 - m^2_1 + i\epsilon} \times \frac{g_{\gamma D_s^* DK}}{q^2 - m^2_2 + i\epsilon} (P+2q)^\mu \epsilon_\mu(D_s^*) $$ (A1)

Both diagrams in figure 4 imply vector-scalar mixing, which appears through the longitudinal part of the vector meson propagator. Indeed, let us consider the diagrams of figure 4 for the vector meson propagator.
a) \[
\frac{D_s^*}{\gamma}\mu P \nu + \]

b) \[
\mu P \gamma D_s^*(2317) \omega \nu \]

\[
\int D^\mu D_s^* D_s^\nu P_\mu P_\nu \gamma^\nu - i \sum \frac{\epsilon^\mu(D_s^*)\epsilon^\nu(D_s^*)}{P^2 - M^2 + i\epsilon} (A2) \]

\[
D^\mu(D_s^*) = \left( -g^{\mu\nu} + \frac{P^\mu P^\nu}{P^2} \right) \frac{1}{P^2 - M^2 + i\epsilon} + \frac{P^\mu P^\nu}{P^2 M^2} (A3) \]

Where in eq. (A3) we separated explicitly the propagator into its transverse (first) and longitudinal (second) components. Analogously, figure 5b provides a contribution to the \( D_s^* \) propagator given by:

\[
iD^{(b)}(P) = i \sum \frac{\epsilon^\mu(D_s^*)\epsilon^\nu(D_s^*)}{P^2 - M^2 + i\epsilon} (-i)\gamma\epsilon^\nu(D_s^*) (A4) \]

\[
D^{(b)}(P) = \frac{P^\mu P^\nu}{M^2} J(P^2)^2 \frac{1}{P^2 - m_{D_s^*}^2 - i\epsilon} (A5) \]

The iteration of the last diagram of figure 5 and the sum of all these terms leads to a geometrical series which renormalizes the longitudinal part of the vector propagator and leads to:

\[
\frac{P^\mu P^\nu}{P^2 M^2} \rightarrow \frac{P^\mu P^\nu}{P^2 M^2} \left( 1 - \frac{P^2 M^2}{P^2 - m_{D_s^*}^2} \right) \frac{1}{P^2 - m_{D_s^*}^2 - i\epsilon} (A6) \]

Now comes an important renormalization condition which is the physical requirement that the longitudinal part of the vector meson propagator does not contain a pole of the scalar meson \([44, 45]\). This condition is only fulfilled if

\[
J(P^2 = m_{D_s^*}^2) = 0. (A7) \]

Next we evaluate the two terms in the amplitude of figure 6:

\[
- iT^{(a)} = - i \gamma\omega(2Q + K) P^\mu P_\mu (A8) \]

\[
- iT^{(b)} = - i J(P^2) P^\mu P_\mu (D_s^*) (A9) \]

As we can see, independently of the \( \gamma\omega \) coupling, the term \( T^{(b)} \) is proportional to \( J(P^2 = m_{D_s^*}^2) \), which we have shown before to be zero due to the renormalization condition of the longitudinal part of the vector meson propagator.

Our procedure to evaluate the amplitude, hence, relies upon:

1) The whole set of diagrams is gauge invariant.
2) The diagrams of figure 7 do not give contribution to the amplitude.
3) Only the set of diagrams of figure 8 give contribution.
4) Using gauge invariance and the procedure followed through eqs. (9-11), only the \( d \) term has to be evaluated, to which only the diagrams of figure 9 and 10 contribute.
