Small cancellation theory over Burnside groups

Rémi Coulon, Dominik Gruber

October 9, 2017

Abstract

We develop a theory of small cancellation theory in the variety of Burnside groups. More precisely, we show that there exists a critical exponent \( n_0 \) such that for every odd integer \( n \geq n_0 \), the well-known classical \( C'(1/6) \)-small cancellation theory, as well as its graphical generalization and its version for free products, produce examples of infinite \( n \)-periodic groups. Our result gives a powerful tool for producing (uncountable collections of) examples of \( n \)-periodic groups with prescribed properties. It can be applied without any prior knowledge in the subject of \( n \)-periodic groups.

As applications, we show the undecidability of Markov properties in classes of \( n \)-periodic groups, we produce \( n \)-periodic groups whose Cayley graph contains an embedded expander graphs, and we give an \( n \)-periodic version of the Rips construction. We also obtain simpler proofs of some known results like the existence of uncountably many finitely generated \( n \)-periodic groups and the SQ-universality (in the class of \( n \)-periodic groups) of free Burnside groups.

1 Introduction

Let \( n \) be an integer. A group \( G \) is periodic of exponent \( n \) (or simply \( n \)-periodic) if it satisfies the law \( x^n = 1 \), i.e. for every element \( g \in G \), we have \( g^n = 1 \). The Burnside variety of exponent \( n \), denoted by \( \mathcal{B}_n \), is the class of all \( n \)-periodic groups. The study of this variety was initiated by W. Burnside in 1902 who asked whether a finitely generated group in \( \mathcal{B}_n \) is necessarily finite [11]. Burnside’s problem inspired a number of significant developments in combinatorial and geometric group theory throughout the twentieth century and has been resolved negatively in the case that \( n \) is large enough (see Novikov-Adian [34], Ol’shanskii [36], Lysenok [31], Ivanov [27], Delzant-Gromov [16], and Coulon [13]). Despite much progress, many aspects of Burnside varieties remain unexplored, in part owing to the fact that it is generally a non-trivial task to even write down a single new example of an infinite \( n \)-periodic group. One purpose of our paper is to remedy this difficulty.

This article provides a versatile and easy-to-apply tool for constructing examples of finitely generated infinite \( n \)-periodic groups with prescribed properties. While examples of such groups have already appeared in the literature, their constructions rely on heavy technical machinery [3, 37] involved to solve the Burnside problem. By contrast, the tool we provide can be applied without any prior knowledge on \( n \)-periodic groups.

We develop a small cancellation theory in Burnside varieties which is the exact analogue of the usual \( C'(1/6) \)-small cancellation theory, in its classical forms and its recent graphical generalizations. Recall that small cancellation theory has, ever since the mid-twentieth century, provided
a seemingly unending source of—often very explicit—examples of infinite groups with striking properties in a wide range of contexts. It has produced results on solvability and unsolvability of algorithmic decision problems [17, 43], it has made major contributions to the understanding of features of negative and non-positive curvature in groups [19, 40, 50, 25, 5], it plays a major role in the understanding of random groups [20], and it has provided the only source of groups containing expanders in their Cayley graphs and therefore satisfying exceptional analytic properties [21, 6, 39]. Our result thus makes the method for constructing such groups available in a Burnside variety.

Before stating our main theorem precisely, we motivate our work with a few applications.

**Notations.** In this article $\mathbb{N}$ (respectively $\mathbb{N}^*$) stands for the set of non-negative (respectively positive) integers.

**Periodic monster groups.** Small cancellation theory is a powerful tool for exhibiting groups with exotic properties. Gromov's monster groups are such examples. Using a graphical version of small cancellation theory, Gromov built finitely generated groups that coarsely contain expander graphs in their Cayley graphs [21], see also [6, 39]. As a consequence, they do not coarsely embed into Hilbert spaces, and therefore they do not have Yu's property $A$ [51], and they are counterexamples to the Baum-Connes conjecture with coefficients [26]. Gromov's groups and related constructions are currently the only source of examples of groups with any of these three properties. While these constructions necessarily produce groups with infinite order elements, we are able to show that such Gromov's monsters also exist in a Burnside variety.

**Theorem 1.1** (Gromov's monster, see Theorem 2.13). There exists $n_0 \in \mathbb{N}$ such that for every odd exponent $n \geq n_0$, there exists a group $G \in \mathcal{B}_n$ generated by a finite set $S$ such that the Cayley graph of $G$ with respect to $S$ contains an embedded (and, moreover, coarsely embedded) expander graph. In particular, there exists a finitely generated $n$-periodic group that does not have Yu’s property $A$, that does not coarsely embed in a Hilbert space and that does not satisfy the Baum-Connes conjecture with coefficients.

**Decision problems in Burnside varieties.** One very important question in group theory is to understand what properties of a group can be checked algorithmically. The word problem is probably one of the most famous instances of this question. For a group $G$ given by a finite (or recursively enumerable) presentation $\langle S \mid R \rangle$, it asks if there exists an algorithm which can decide whether or not a word in the alphabet $S \cup S^{-1}$ represents the identity element. It was proved by Novikov that there exists a group without solvable word problem [33]. Building on this example, Adian and Rabin showed the following fact [1, 42]. Given a Markov property $\mathcal{P}$, there is no algorithm that takes a finite presentation and decides whether or not the corresponding group has $\mathcal{P}$. Roughly speaking, this means that most of the non-trivial decision problems one can think of are unsolvable in the class of all groups. However if one restricts attention to a smaller class (e.g. abelian groups, nilpotent groups, hyperbolic groups, etc) then many decision problems become solvable. It is therefore natural to ask what decision problems can be solved in a Burnside variety $\mathcal{B}_n$.

We show here the exact analogue of Adian-Rabin theorem in $\mathcal{B}_n$. As it remains unknown whether there exists an infinite finitely presented periodic group, in our approach of decision problems we consider groups which are finitely presented relative to $\mathcal{B}_n$. To that end we briefly give terminology for our statement. Given a group $G$, we write $G^n$ for the (normal) subgroup of $G$.
generated by then \( n \)-th power of all its elements. Recall that the free Burnside group of exponent \( n \) generated by a set \( S \), is defined by

\[
B_n(S) = F(S)/F(S)^n = \langle S \mid x^n = 1, \forall x \rangle.
\]

It is the free element of \( B_n \). This means that given a group \( G \in B_n \), any map \( S \to G \) uniquely extends to a homomorphism \( B_n(S) \to G \). We say that a group \( G \in B_n \) is finitely presented relative to \( B_n \) if \( G \) is isomorphic to the quotient of a finitely generated free Burnside group \( B_n(S) \) by the normal closure of a finite subset of \( B_n(S) \). Equivalently, \( G \) is the quotient of a finitely presented group \( G_0 = \langle S \mid R \rangle \) by \( G_0^n \). In this situation we will refer to \( \langle S \mid R \rangle \) as a finite presentation relative to \( B_n \).

**Theorem 1.2** (see Theorem 2.9). There exists a critical exponent \( n_0 \in \mathbb{N} \) with the following property. Let \( n \geq n_0 \) be an odd integer that is not prime. Let \( P \) be a subclass of \( B_n \) for which there exist \( G_+,G_- \in B_n \) which are finitely presented relative to \( B_n \) such that

(i) the group \( G_+ \) belongs to \( P \),

(ii) any \( n \)-periodic group containing \( G_- \) as a subgroup does not belong to \( P \).

Then there is no algorithm that takes as input a finite presentation relative to \( B_n \) and determines whether the corresponding group \( G \in B_n \) belongs to \( P \) or not.

Our proof relies on a result of Karlampovich, who showed that if \( n \) is a sufficiently large exponent that is not prime then there exists a group \( G \in B_n \) which is finitely presented relative to \( B_n \) without solvable word problem [28]. The following is an immediate consequence of our theorem.

**Corollary 1.3** (see Corollary 2.10). There exists a critical exponent \( n_0 \in \mathbb{N} \), such that for every odd integer \( n \geq n_0 \) which is not prime, the following properties are algorithmically undecidable from finite presentations relative to \( B_n \) begin trivial, finite, cyclic, abelian, nilpotent, solvable, amenable.

Another famous application of small cancellation theory is the Rips’ construction [43]. It shows that every finitely presented group \( Q \) is the quotient of a (hyperbolic) small cancellation group \( G \) by a finitely generated normal subgroup \( N \). In particular it allows to transfer various pathological properties of \( Q \) to the subgroups of \( G \) (see for instance Baumslag-Miller-Short [8]). Our approach of small cancellation theory over Burnside groups provides an analogue of Rips’ construction (see Theorem 2.11).

**New proofs of known results.** Our main result also enables us to give explicit constructions that provide concise new proofs of the following known results.

**Theorem 1.4** (Atabekyan [7], see Example 2.5). There exists \( n_0 \in \mathbb{N} \), such that for every odd integer \( n \geq n_0 \), for every \( r \geq 2 \), there are uncountably many groups of rank \( r \) in \( B_n \).

A group \( G \) is SQ-universal in \( B_n \) if for every countable group \( C \in B_n \) there exists a quotient \( Q \) of \( G \) such that \( C \) embeds into \( Q \).

**Theorem 1.5** (Sonkin [46], see Theorem 2.14). There exists \( n_0 \in \mathbb{N} \) such that for every odd exponent \( n \geq n_0 \), for every set \( S \) containing at least two elements, the free Burnside group \( B_n(S) \) is SQ-universal in \( B_n \).
The small cancellation theorem. Let us present now a simplified version of our main result. We use the usual definition of the classical $C'(\lambda)$-condition [30, Chapter V]; see also Definition 2.1. Roughly speaking, this condition on a presentation requires that whenever two relators $r \neq r'$ have a common subword $u$, then $|u| < \lambda \min\{|r|, |r'|\}$.

Theorem 1.6. Let $p \in \mathbb{N}^*$. There exists $n_p \in \mathbb{N}$ such that for every odd integer $n \geq n_p$ the following holds. Let $G = \langle S \mid R \rangle$ be a non-cyclic group given by a classical $C'(1/6)$-presentation. Assume that no $p$-th power of a word is a subword of an element of $R$, and no $r \in R$ is a proper power. Then the quotient $G/G^n$ is infinite.

Note that there is no restriction on the cardinalities of $S$ or $R$ or on the length of the relations in $R$. The constant $n_p$ only depends on $p$. In practice, $p$ will never be larger than 10. Hence, $n_p$ can be thought of as a universal constant.

Our proof, in fact, yields the much more general Theorems 2.4 and 6.3, encompassing Gromov’s graphical small cancellation theory, as well as classical and graphical small cancellation theory over free products. The philosophy is always similar to the one of Theorem 1.6: if the small cancellation presentation defines a non-elementary group, and if some restrictions on proper powers are satisfied, then some of the standard conclusions of small cancellation theory hold. For example, $n$-periodic graphical small cancellation produces infinite $n$-periodic groups with prescribed subgraphs in their Cayley graphs, and $n$-periodic free product small cancellation produces infinite $n$-periodic quotients of free products of $n$-periodic groups in which each of the generating free factors survives as subgroup.

Remark 1.7. Even in the case that both $S$ and $R$ are finite, the statement of Theorem 1.6 is not covered by prior results. It is known [38, 16] that, given a torsion-free Gromov hyperbolic group $G$, there exists $n_G \in \mathbb{N}$ such that for all odd integers $n \geq n_G$, the quotient $G/G^n$ is infinite. Note here that $n_G$ depends on the specific group $G$ and, in fact, given an exponent $n \in \mathbb{N}$, the proof only applies to finitely many hyperbolic groups $G$ of a given rank. In our result, on the other hand, the constant $n_p$ is independent of the presentation $\langle S \mid R \rangle$. We shall see in the following how this easily enables us to construct, for any $n \geq n_p$ odd, infinitely many (and, in fact, uncountably many) examples of infinite $n$-periodic groups (say, of rank 2).

Strategy of proof. Our small cancellation assumption in Theorem 1.6 has two parts. The first is the usual $C'(\lambda)$ small cancellation condition requiring that any two elements of $R$ must have small common subwords – this condition is a standard tool for producing infinite “negatively curved” groups. Together with the assumption that no relation $r \in R$ is a proper power, it also ensures that $G$ is torsion-free. This prevents $G$ from having torsion that would be incompatible with the $n$-torsion introduced later on.

The second part of our assumption requires a uniform bound on the powers appearing as subwords of elements of $R$. This essentially tells us that the elements of $R$ are “transverse to the Burnside relations” of the form $x^n = 1$. For some specific adhoc constructions, experts of Burnside groups implicitly observed that adding appropriate aperiodic relations should not affect significantly the proof of the infiniteness of $B_n(S)$ [37]. However their method requires to re-run the full proof of the Novikov-Adian theorem. Our approach of Theorem 1.6 has the following advantage: we are able to treat completely separately the relations of $G/G^n$ coming from $R$ and the Burnside relations. In particular, our approach provides a better geometric understanding of the bounded
torsion groups that arise as small cancellation quotients of free Burnside groups. We now briefly describe the strategy of our proof.

The first step is to study the geometry of groups defined by $C'(1/6)$ small cancellation presentations. If $G = \langle S \mid R \rangle$ is such a group, denote by $W$ all elements of $G$ represented by subwords of elements of $R$. Consider the Cayley graph $\hat{X}$ of $G$ with respect to the (possibly infinite) generating set $S \cup W$. Thus, as graph, $\hat{X}$ is obtained from the usual Cayley graph by attaching to each embedded cycle $\gamma$ that corresponds to a relator in $R$ a complete graph on the vertices of $\gamma$. Gruber and Sisto proved that $\hat{X}$ is Gromov hyperbolic, and the natural action of $G$ on $\hat{X}$ is non-elementary unless $G$ is virtually cyclic [25]. In our work, we study the action of $G$ on $\hat{X}$ and prove that, in fact, our second assumption (the one regarding powers appearing as subwords of relations) ensures that the action of $G$ on $\hat{X}$ is acylindrical. We also determine the non-trivial elliptic elements for the action of $G$ on $\hat{X}$. In the case of Theorem 1.6, we show that there are none.

The second step of the proof is to “burnsidify” the group $G$ by killing all possible $n$-th powers. To this end we use a theorem of Coulon that can be roughly summarized as follows [14]. Assume that $G$ is a group without involution acting acylindrically non-elementary on a hyperbolic space $\hat{X}$. Then there exists a critical exponent $n_0 \in \mathbb{N}$ such that for every odd integer $n \geq n_0$, there exists an infinite quotient $G_n$ of $G$ with the following properties: every elliptic subgroup of $G$ embeds into $G_n$, and for every element $g \in G_n$ that is not the image of an elliptic element of $G$, we have $g^n = 1$. In the settings of Theorem 1.6, $G$ has no non-trivial elliptic element, hence the quotient $G_n$ obtained from Coulon’s result is exactly $G/G_n$. Coulon’s theorem, moreover, proves that the map $G \to G_n$ preserve the small scale geometry induced by the metric of $\hat{X}$. This lets us prove that certain non-trivial elements of $G$ survive in $G_n$. In particular, it enables us to promote small cancellation constructions of groups with certain prescribed subgraphs (e.g. expander graphs) to the setting of $n$-periodic groups.

We explain why the critical exponent $n_p$ in Theorem 1.6 only depends on $p$. The hyperbolicity constant of Gruber and Sisto’s space $\hat{X}$ is uniform, i.e. independent of the specific $C'(1/6)$-presentation $\langle S \mid R \rangle$. Our proof shows that the acylindricity parameters for the action of $G$ on $\hat{X}$ only depend on the number $p$ that provides the bound on powers appearing as subwords of relators. Finally, the critical exponent given by Coulon’s theorem only depends on the those parameters. In other words, the uniform control on powers appearing as subwords of elements of $R$, i.e. the degree of transversality to the Burnside relators, has a very strong geometric interpretation in term of the action of $G$ on $\hat{X}$, which gives us the desired control on $n_p$.

Outline of the article. In Section 2 we state the main results of the article and give a proof of the applications exposed in the introduction. Section 3 reviews some basic facts about hyperbolic geometry and acylindrical actions on hyperbolic spaces. Section 4 is devoted to the second step of the aforementioned strategy. We explain how given a group $G$ acting acylindrically on a hyperbolic space $X$, we can turn $G$ into a periodic group with exponent $n$. In particular we highlight the fact that the exponent $n$ does not depend on the group $G$, but only on the parameters of the acylindrical action. In Section 5 we show that a group $G$ statisfying a suitable small cancellation condition acts acylindrically on its hyperbolic coned-off Cayley graph. Moreover we explain how the parameters of this action are related to those of our small cancellation assumption. The final section provides the proofs of the main theorems stated in Section 2 using the results of Section 4 and Section 5.

2 Main results

In this section we state the main results of the article and explain how they can be applied to cover all the examples exposed in the introduction.

2.1 Small cancellation

Before stating its graphical generalization, we remind the reader of the classical $C'(\lambda)$-condition for reference. Our definition corresponds to the standard one given, for example, in the book of Lyndon and Schupp [30, Chapter V].

Definition 2.1 (Classical small cancellation). Given a presentation $\langle S \mid R \rangle$, a *piece* is a word $u$ that is a common prefix of two distinct cyclic conjugates of elements of $R \cup R^{-1}$. We say $\langle S \mid R \rangle$ satisfies the classical $C'(\lambda)$-condition if every element of $R$ is cyclically reduced and if whenever a classical piece $u$ is a subword of a cyclic conjugate of some $r \in R$, then $|u| < \lambda |r|$.

Group defined by a labelled graph. A graph is a graph in the sense of Serre [45]. Let $S$ be a set. A *labelled* graph is a graph $\Gamma = (V, E)$ together with a map $E \to S \sqcup S^{-1}$ that is compatible with the inversion map. If we write $\Gamma$ as disjoint union of its connected components $\Gamma = \sqcup_{i \in I} \Gamma_i$ and, for each $\Gamma_i$ choose a vertex $v_i$, then the labelling induces a natural map $\pi_i: \Gamma_i \to F(S)$. The group $G(\Gamma)$ is defined as the quotient of $F(S)$ by the normal closure of the image of this map. Note that this normal closure, and hence $G(\Gamma)$, does not depend on the choice of the vertices $v_i$.

The group $G(\Gamma)$ can be also described by a specific presentation. Given a path $\gamma$ in $\Gamma$, the *label* of $\gamma$, denoted $\ell(\gamma)$, is the product of the labels of its edges seen as an element of the free monoid on $S \sqcup S^{-1}$. A presentation of $G(\Gamma)$ is

$$G(\Gamma) := \langle S \mid \text{labels of simple closed paths in } \Gamma \rangle$$

Let $\text{Cay}(G(\Gamma), S)$ be the Cayley graph of $G(\Gamma)$ with respect to $S$. If $v_i$ is a vertex in a connected component $\Gamma_i$ of $\Gamma$ and $g \in G(\Gamma)$, then there exists a unique label-preserving graph homomorphism $\Gamma_i \to \text{Cay}(G(\Gamma), S)$ that maps $v_i$ to $g$.

Small cancellation condition. Let $\Gamma$ be a graph labelled by a set $S$. A *piece* is a word $w$ over the alphabet $S \sqcup S^{-1}$ labelling two paths $\gamma_1$ and $\gamma_2$ in $\Gamma$ so that there is no label preserving automorphism $\varphi$ of $\Gamma$ such that $\gamma_2 = \varphi \circ \gamma_1$. 

Definition 2.2 (Graphical small cancellation [22, Definition 1.3]). Let \( \lambda \in (0, 1) \). Let \( \Gamma \) be a graph labelled by a set \( S \). We say that \( \Gamma \) satisfies the \( C'(\lambda) \) small cancellation condition if the following holds.

(i) The graph \( \Gamma \) is reduced in the following sense: two edges with the same initial vertex cannot have the same label.

(ii) For every simple loop \( \gamma \) in \( \Gamma \), the \( w \) is a piece labelling a subpath of \( \gamma \), then \( |w| < \lambda|\gamma| \) where \(|.| \) stands for the length of words/paths.

This settings extends the classical small cancellation. Indeed Definition 2.1 exactly corresponds to the case where \( \Gamma \) is a disjoint union of circle graphs, each of them being labelled by a distinct relation \( r \in R \).

In order to state the next theorem we define a strengthening of the small cancellation condition. To perform small cancellation in the variety \( B_n \) we need indeed an assumption to ensure that the relation we consider are “transverse to the Burnside relations”. The idea is to require that the words labelling path in \( \Gamma \) are not large power, unless they already corresponds to an \( n \)-th power labelling a closed path.

Definition 2.3 (Periodic small cancellation). Let \( n, p \in \mathbb{N} \) and \( \lambda \in (0, 1) \). Let \( \Gamma \) be a graph labelled by a set \( S \). We say that \( \Gamma \) satisfies the \( C'_n(\lambda, p) \) small cancellation assumption if the following holds.

(i) The graph \( \Gamma \) is strongly reduced in the following sense: every edge has two distinct vertices; there is no closed path with label \( st^{-1} \) for \( s, t \in S, s \neq t \).

(ii) \( \Gamma \) satisfies the \( C'(\lambda) \)-condition.

(iii) Whenever \( w \) is a cyclically reduced word such that \( w^p \) labels a path in \( \Gamma \), then \( w^n \) labels a closed path in \( \Gamma \).

Let \( n \in \mathbb{N} \). Following the construction above, we define the analogue of \( G(\Gamma) \) in the Burnside variety \( B_n \). For each connected component \( \Gamma_i \) of \( \Gamma \) we choose a vertex \( v_i \in \Gamma_i \). The labelling \( \ell \) of \( \Gamma \) induces a map \( *_{i \in I} \pi_1(\Gamma_i, v_i) \rightarrow B_n(S) \). The group \( G_n(\Gamma) \) is defined as the quotient of \( B_n(S) \) by the normal closure of the image of this map. Again this construction does not depend on the choice of the vertices \( v_i \). The group \( G_n(\Gamma) \) can also be described as the \( n \)-periodic quotient of \( G(\Gamma) \). More precisely, \( G_n(\Gamma) \) is the quotient of \( G(\Gamma) \) by the (normal) subgroup of \( G(\Gamma) \) generated by the \( n \)-th power of all its elements. As previously, if \( v_i \) is a vertex in a connected component \( \Gamma_i \) of \( \Gamma \) and \( g \in G_n(\Gamma) \), then there exists a unique label-preserving graph homomorphism \( \Gamma_i \rightarrow \text{Cay}(G_n(\Gamma), S) \) that maps \( v_i \) to \( g \).

Theorem 2.4. Let \( p \in \mathbb{N} \). There exists a critical exponent \( n_p \in \mathbb{N} \) such that for every odd integer \( n \geq n_p \) the following holds. Let \( S \) be a set containing at least two elements. Let \( \Gamma \) be a graph labelled by \( S \) satisfying the \( C'_n(1/6, p) \) condition. We assume that there is no finite group \( F \) generated by \( S \) whose Cayley graph \( \text{Cay}(F, S) \) embeds in \( \Gamma \). Then the following holds.

(i) The group \( G_n(\Gamma) \) is infinite.

(ii) Every connected component of \( \Gamma \) embeds into \( \text{Cay}(G_n(\Gamma), S) \) via a label-preserving graph homomorphism.
(iii) If $S$ is finite, $\Gamma$ is countable, and every connected component of $\Gamma$ is finite, then $\Gamma$ embeds and coarsely embeds in $G_n(\Gamma)$.

Recall that a map $f : X_1 \to X_2$ between two metric spaces is a coarse embedding if for all sequences of pairs of points $x_k, y_k \in X_1 \times X_1$ we have $|x_k - y_k|_{X_1} \to \infty \iff |f(x_k) - f(y_k)|_{X_2} \to \infty$. In our theorem, we will consider $\Gamma$ as metric space by writing it as disjoint union of its countably many connected components $\Gamma = \sqcup_{i \in \mathbb{N}} \Gamma_i$, and endowing it with the shortest-path metric on each component and declaring $d(x, y) = \text{diam}(\Gamma_i) + \text{diam}(\Gamma_j) + i + j$ for $x \in \Gamma_i$ and $y \in \Gamma_j$. (This is usually called the box-space metric, and the constants $\text{diam}(\Gamma_i) + \text{diam}(\Gamma_j) + i + j$ we choose are irrelevant in the context of the notion of coarse equivalence.)

The proof of Theorem 2.4 is given in Section 6. We illustrate this statement with a short proof that for an integer $n$ odd and large enough, $\mathcal{B}_n$ is uncountable.

Example 2.5 (Thue-Morse sequence). Let $S = \{a, b, t\}$. Let $u = u(a, b)$ be the infinite Thue-Morse sequence over the alphabet $\{a, b\}$.

$u(a, b) = abbabaabbaabababaabbaabbababababababababababababab\ldots$

It is the infinite word obtained from $a$ by iterating the substitution $a \to ab$ and $b \to ba$. It has the property that it does not contain any subword of the form $w^3$ [49]. For every $k \in \mathbb{N}$, we consider a subword $u_k = u_k(a, b)$ of length $k$ of $u$. For every $i \in \mathbb{N}$, we now consider a collection of words $r_i$ of the form

$$r_i = tu_{100i+1}tu_{100i+2}t \ldots tu_{100i+100}.$$

Let $n_p$ be the critical exponent given by Theorem 2.4 for $p = 3$. We fix an odd integer $n \geq n_p$. Let $I$ be a subset of $\mathbb{N}$. We define a graph $\Gamma_I$ as the disjoint union of circle graphs indexed by $\mathbb{N}$. The $i$-th circle graph of $\Gamma_I$ is labelled by $r_i$ if $i \in I$ and $r_i^n$ otherwise. Hence we have

$$G(\Gamma_I) = \langle a, b, t \mid r_i, r_j^n, i \in I, j \in \mathbb{N} \setminus I \rangle.$$

Observe that, since $|u_i| \neq |u_j|$ for $i \neq j$ and since no $u_i$ contains any $t$'s, we have that no cyclically reduced word of the form $w^3$ can be read on $\Gamma_I$, unless $w^3$ labels a closed path. Furthermore, no piece contains two $t$'s, whence it is easy to check that $\Gamma_I$ satisfies the $C'(1/6)$-condition. Therefore, $\Gamma_I$ satisfies the $C_n'(1/6, 3)$-assumption. Applying Theorem 2.4 yields that each $G_n(\Gamma_I)$ is infinite. Of course the relations of the form $r_j^n$ for $j \in \mathbb{N} \setminus I$ are irrelevant for the definition of $G_n(\Gamma_I)$. Nevertheless keeping track of them in $\Gamma_I$ will help us to distinguish between all the $G_n(\Gamma_I)$.

We now prove that we obtain uncountably many isomorphism classes of $n$-periodic groups in this way. For every $I \subset \mathbb{N}$ we denote by $K_I$ the kernel of the canonical projection $F(a, b, t) \to G_n(\Gamma_I)$. As $n > 1$, Theorem 2.4 (ii) applied to $\Gamma_I$ implies that whenever $j \notin I$, then $r_j$ does not represent the identity in $G_n(\Gamma_I)$. Consequently $K_I = K_J$ if and only if $I = J$. Now, given one (isomorphism type of) countable group $C$, there are only countably many kernels of homomorphisms $F(a, b, t) \to C$. Hence, the collection \{ $G_n(\Gamma_I) : I \subseteq \mathbb{N}$ \} must contain uncountably many isomorphism types of groups.

Example 6.5, which is detailed at the end of the article, explains why the assumption regarding powers in Definition 2.3 (iii) is necessary.
2.2 Small cancellation over free products

We now describe an analogue of Theorem 1.6 in the context of small cancellation over free products. We refer the reader to Theorem 6.3 for the full (graphical) statement. We follow here the general exposition given in Lyndon-Schupp [30]. Let

\[ F = F_1 * F_2 * \cdots * F_m \]

be a free product. Recall that any non-trivial element \( g \in F \) can be decomposed in a unique way as a product

\[ g = g_1 g_2 \cdots g_\ell \]

where each \( g_i \) is a non trivial element of some factor \( F_k \), and no two consecutive \( g_i \) and \( g_{i+1} \) belong to the same factor. Such a decomposition is called the normal form of \( g \). The integer \( \ell \) is the syllable length of \( g \) and we denote it by \(|g|_s\). Let \( g = g_1 g_2 \cdots g_r \) and \( h = h_1 h_2 \cdots h_s \) be two elements of \( F \) given by their normal forms. The product \( gh \) is called weakly reduced if \( g h_1 \) is non-trivial. Note that one allows \( g \) and \( h_1 \) to be the in the same factor. An element \( g = g_1 \cdots g_\ell \) given by its normal form is cyclically reduced if \( \ell = 1 \) or \( g_1 \) and \( g_\ell \) are not in the same factor. It is weakly cyclically reduced if \( \ell = 1 \) or \( g_1 g_1 \) is non-trivial. A subset \( R \) of \( F \) is called symmetrized if its elements are cyclically reduced and for every \( r \in R \), all the weakly cyclic conjugates of \( r \) and \( r^{-1} \) belong to \( R \). In this context a piece is an element \( u \in F \) for which there exist \( r_1 \neq r_2 \) in \( R \) which can be written in weakly reduced form as \( r_1 = u v_1 \) and \( r_2 = u v_2 \).

**Definition 2.6.** Let \( \lambda \in (0,1) \). A symmetrized subset \( R \) of \( F \) satisfies the power-free \( C^\prime_\lambda (\lambda) \) small cancellation condition if

(i) For every \( r \in R \), which can be written in a weakly reduced form as \( r = u v \) where \( u \) is a piece, then \(|u|_s < \lambda |r|_s \). To avoid pathologies we also require that for every \( r \in R \), \(|r|_s > 1/\lambda \).

(ii) No element of \( R \) is a proper power.

By analogy with the graphical case we now define the assumption needed to perform small cancellation over free products in a Burnside variety \( \mathcal{B}_n \). Our assumption here is somehow stronger than its graphical analogue. Indeed we do not allow relations to be a proper power. Hence the definition does not depend on the Burnside exponent \( n \). We actually cover a more general free product small cancellation condition that does allow relators that are proper powers in Theorem 6.3 but choose to here cover the following version for simplicity.

**Definition 2.7.** Let \( p \in \mathbb{N} \). Let \( \lambda \in (0,1) \). A symmetrized subset \( R \) of \( F \) satisfies the power-free \( C^\prime_\lambda (\lambda,p) \) small cancellation condition if the following holds.

(i) \( R \) satisfies the power-free \( C^\prime_\lambda (\lambda) \)-assumption

(ii) For every \( r \in R \), if there exists a cyclically reduced element \( w \) with \(|w|_s > 1 \) such that \( r \) can be written in a weakly reduced form as \( r = (w^k) v \) then \( k \leq p \).

**Theorem 2.8.** Let \( p \in \mathbb{N}^* \). There exists \( n_p \in \mathbb{N} \) such that for every odd exponent \( n \geq n_p \) the following holds. Let \( F = F_1 * \cdots * F_m \) be a free product. Let \( R \) be a symmetrized subset of \( F \) satisfying the power-free \( C^\prime_\lambda (1/6,p) \) condition. We assume that no factor in \( F \) has even torsion. Then there exists a quotient \( Q_n \) of \( G = F/\langle \langle R \rangle \rangle \) with the following properties.
(i) Every factor $F_k$ embeds in $Q_n$.

(ii) For every $g \in Q_n$, if $g$ is not conjugate to an element in a factor $F_k$, then $g^n = 1$.

(iii) If every factor $F_k$ belongs to $\mathcal{B}_n$, then $Q_n = G/G^n$. In particular $Q_n$ belongs to $\mathcal{B}_n$.

The proof of Theorem 2.8 is given in Section 6.

2.3 Decision problems and Rips’ construction

We now present a few applications of Theorems 2.4 and 2.8. We start with the following analogue the Adian-Rabin theorem.

**Theorem 2.9.** There exists a critical exponent $n_0$ with the following property. Let $n \geq n_0$ be an odd integer that is not prime. Let $\mathcal{P}$ be a subset of $\mathcal{B}_n$ for which there exist $G_+, G_- \in \mathcal{B}_n$ which are finitely presented relative to $\mathcal{B}_n$, such that

(i) the group $G_+$ belongs to $\mathcal{P}$,

(ii) any $n$-periodic group containing $G_-$ as a subgroup does not belong to $\mathcal{P}$.

Then there is no algorithm that takes as input a finite presentation relative to $\mathcal{B}_n$ and determines whether the corresponding group $G \in \mathcal{B}_n$ belongs to $\mathcal{P}$ or not.

**Proof.** Recall that all the presentations we consider here are relative to $\mathcal{B}_n$. Nevertheless, for simplicity, we omit in this proof the mention “relative to $\mathcal{B}_n$”. Let $n_p \in \mathbb{N}$ be the critical exponent given by Theorem 2.8 with $p = 10$. Up to increasing the value of $n_p$, we can assume that $n_p \geq (665)^2$. Let $n \geq n_p$ be an odd exponent that is not prime. In particular $n$ decomposes as $n = pq$ where $p \geq 3$ is prime and $q$ has an odd divisor larger than 665. According to [28] there exists a finitely presented group $H \in \mathcal{B}_n$ whose word problem is not solvable. We write $S$ for the corresponding generating set of $H$.

Let $\mathcal{P}$ be a class of group satisfying the assumptions of the theorem. Let $G_+$ be a finitely presented group in $\mathcal{P}$. Let $G_-$ be a finitely presented group such that any group in $\mathcal{B}_n$ containing $G_-$ is not in $\mathcal{P}$. We write $S_-$ and $S_+$ for the generating sets of the presentation defining $G_-$ and $G_+$ respectively.

To each word $w$ over the alphabet $S \cup S^{-1}$ we are going to produce a finitely presented test group $L_n(w)$ in $\mathcal{B}_n$ such that $L_n(w)$ belongs to $\mathcal{P}$ if and only if $w$ represents the trivial element. The construction goes as follows. We consider $C$, $C_1$ and $C_2$, three distinct copies of $\mathbb{Z}/n\mathbb{Z}$. We write $t$, $x_1$ and $x_2$ for a generator of $C$, $C_1$ and $C_2$ respectively. We consider the following free product.

$$L_0 = H \ast G_+ \ast G_- \ast C \ast C_1 \ast C_2$$

Let $w$ be a word over $S \cup S^{-1}$. We now construct a quotient $L(w)$ of $L_0$. Let $h$ the element of $H$ represented by $w$. We write $g_i$ for the commutator $[h, x_i]$. Let $u(a, b)$ be the infinite Thue-Morse sequence over the alphabet $\{a, b\}$ (see Example 2.5). For every $k \in \mathbb{N}$, $u_k(a, b)$ is a subword of length $k$ of $u(a, b)$. The group $L(w)$ is the quotient of $L_0$ characterized by the following families of relations: for every $s \in S \cup S_- \cup \{t, x_1, x_2\}$,

$$s = u_{k_s,1}(g_1, g_2)t u_{k_s,2}(g_1, g_2)t^{-1} u_{k_s,3}(g_1, g_2)t \cdots u_{k_s,2p_s}(g_1, g_2)t^{-1}.$$  (1)
where the sequence \((k_{s,j})\) will be made precise later. We now define \(L_n(w)\) as the \(n\)-periodic quotient of \(L\), i.e. \(L_n(w) = L(w)/L(w)^n\), where \(L(w)^n\) is the (normal) subgroup of \(L(w)\) generated by the \(n\)-th power of all its elements.

If \(w\) represents the trivial element in \(H\), i.e. if \(h = 1\), then \(g_1\) and \(g_2\) are trivial as well. Hence the relations (1) force \(H, G_-, C, C_1\) and \(C_2\) to have a trivial image in \(L(w)\). Consequently \(L(w)\) is isomorphic to \(G_+\). As \(G_+\) is already \(n\)-periodic, \(L_n(w)\) is isomorphic to \(G_+\). In particular \(L_n(w)\) belongs to \(\mathcal{P}\). Assume now that \(w\) does not represents the trivial element in \(H\). In other words, \(h \neq 1\). Then \(g_1\) and \(g_2\) are two non-trivial elements of \(H\). For every such relation \((k_{s,j})\) in such a way that the relations (1) defining \(L(w)\) satisfy the power-free small cancellation assumption \(C_+^1(1/6, 10)\). It follows from Theorem 2.8 that \(G_-\) embeds in \(L_n(w)\). According to our assumption on \(G_+\), the group \(L_n(w)\) cannot belong to \(\mathcal{P}\). Hence the group \(L_n(w)\) has the announced property.

Note that the sequence \((k_{s,j})\) can be chosen independently of \(w\). Hence the presentation of \(L(w)\) can be algorithmically computed from the respective presentations of \(G_+, H, C, C_1\) and \(C_2\). It follows from this discussion that deciding whether or not a finitely presented group of \(\mathfrak{S}_n\) belongs to \(\mathcal{P}\) is equivalent to solving the word problem in \(H\). The latter problem being unsolvable, so is the former one.

**Corollary 2.10.** There exists a critical exponent \(n_0\) with the following property. Let \(n \geq n_0\) be an odd integer that is not prime. Let \(\mathcal{P}\) be one of the following property: being trivial, finite, cyclic, abelian, nilpotent, solvable, amenable. There is no algorithm to determine whether a group \(G\) of \(\mathfrak{S}_n\) given by a finite presentation relative to \(\mathfrak{S}_n\) has \(\mathcal{P}\).

The following observation shows that the Rips construction [43], a method for exhibiting pathologies among \(C'(\lambda)\)-small cancellation groups (and thus, in particular, among hyperbolic groups) can also be applied to our class of small cancellation groups in the Burnside variety.

**Theorem 2.11 (Rips construction).** Let \(n \in \mathbb{N}\) and \(\lambda \in (0, 1]\). Let \(Q\) be a finitely generated group in \(\mathfrak{S}_n\). There exists a graph \(\Gamma\) labelled by a finite set \(S\) satisfying the \(C'_n(\lambda, 3)\)-condition with the following properties

(i) \(G_n(\Gamma)\) maps onto \(Q\) and the kernel of this projection is finitely generated.

(ii) If \(Q\) is finitely presented relative to \(\mathfrak{S}_n\) then so is \(G_n(\Gamma)\).

**Proof.** Let \(\langle a_1, \ldots, a_r \mid R\rangle\) be a presentation relative to \(\mathfrak{S}_n\) of \(Q\). Up to conjugating the elements of \(R\) we can assume that their length is at least \(10^{10}\). As usual we write \(u = u(x, y)\) for the infinite Thue-Morse word over the alphabet \(\{x, y\}\). For every \(k \in \mathbb{N}\), \(u_k = u_k(x, y)\) is a subword of length \(k\) of \(u\) (see Example 2.5). We now build a graph \(\Gamma\) labelled by \(S = \{a_1, \ldots, a_r, x, y, t\}\) as follows. For each \(i \in \{1, \ldots, r\}\), for each \(u \in \{x, y, t\}\) for each \(\varepsilon \in \{-1, 1\}\) we associate a loop in \(\Gamma\) labelled by

\[a_i^\varepsilon u a_i^{-\varepsilon} t a_k t a_k^{-1} t \cdots t a_{k_{s,i}}. \tag{2}\]

Let \(r = r_1 \ldots r_m\) be a relation of \(R\) written in the alphabet \(\{a_1, \ldots, a_r\}\). For every such relation we add a new loop to \(\Gamma\) labelled by

\[r_1 u_{k_1} r_2 u_{k_2} \cdots r_m u_{k_m}. \tag{3}\]
In this construction the sequences \((k_j)\) implicitly depends on the relation we are considering. Recall that the Thue-Morse sequence does not contain any cube. Hence one can choose the indices \(k_j\) such that the graph \(\Gamma\) obtained in this way satisfies the \(C'_n(\lambda, 3)\)-assumption. According to the relations (2) the subgroup \(K\) generated by \(x, y\) and \(t\) is normal in \(G_\infty(\Gamma)\). By the relations (3) the quotient of \(G_\infty(\Gamma)\) by \(K\) is exactly \(Q\). Note that, if \(R\) is finite, then \(\Gamma\) is a finite union of disjoint loops. Hence \(G_\infty(\Gamma)\) is finitely presented relative to \(\mathfrak{B}_n\).

**Remark 2.12.** In our proof the kernel \(K\) has rank at most 3. We made this choice to keep the exposition easy. With some additional work one should be able to achieved rank 2.

For the moment we have not found relevant applications of this construction that cannot be recovered by using already existing technologies. Consider for instance the following construction. Let \(n\) be an odd integer and \(Q \in \mathfrak{B}_n\). Applying the *standard* Rips construction, one can find a short exact sequence

\[
1 \to K \to G \to Q \to 1
\]

where \(G\) is a *torsion-free hyperbolic* group and \(K\) a finitely generated group. Then applying Ol’shanski˘ı [38] one can consider the quotient \(G/G^{kn}\) where \(k\) is a large odd integer and \(G^{kn}\) the (normal) subgroup of \(G\) generated by the \(kn\)-th power of all its elements. This provides a short exact sequence

\[
1 \to K_k \to G/G^{kn} \to Q \to 1
\]

where \(G/G^{kn}\) is an infinite periodic group. In this way one can exhibit for instance a periodic group with solvable word problem but unsolvable generalized word problem. Nevertheless the construction given by Theorem 2.11 has the following virtue. Contrary to the aforementioned strategy, the group \(G_\infty(\Gamma)\) that we produce has the same exponent as the group \(Q\) we started with.

### 2.4 Gromov monsters

Our main theorem also enables the transposition of major recent results from analytic group theory to the variety \(\mathfrak{B}_n\).

**Theorem 2.13** (Gromov monster). There exists \(n_0\) such that for every odd exponent \(n \geq n_0\), there exists a group \(G \in \mathfrak{B}_n\) generated by a finite set \(S\) whose Cayley graph with respect to \(S\) contains an embedded (and, moreover, coarsely embedded) expander graph. In particular, there exists a finitely generated \(n\)-periodic group that does not have Yu’s property A, that does not coarsely embed into a Hilbert space and that does not satisfy the Baum-Connes conjecture with coefficients.

**Proof.** Let \(\Gamma = (V, E)\) be an expander graph without simple closed paths of length 1 or 2. In particular \(\Gamma\) is the disjoint union of a collection of finite graphs \((\Gamma_k)\) with uniformly bounded valency. In addition we assume that

- the valence of any vertex is at least 3;
- the girth of \(\Gamma_k\) tends to infinity as \(k\) approaches infinity;
- the ratio \(\text{diam}(\Gamma_k)/\text{girth}(\Gamma_k)\) is uniformly bounded from above.
Such a graph can be obtained as follows [29]: fix the matrices

\[ M_1 = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad M_2 = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix} \]

and consider the sequence of Cayley graphs of the groups $SL_2(\mathbb{Z}/p\mathbb{Z})$, where $p$ runs over all primes, with respect to the images of $M_1$ and $M_2$. We explain how to endow $\Gamma$ with a labelling that satisfies, for every $n \in \mathbb{N}$, the $C'_n(1/6, 2)$ condition. Then it remains to apply Theorem 2.4.

**Labelling the graph.** The ideas of this paragraph come from Arzhantseva, Cashen, Gruber, and Hume [5, Theorem 6.8]. We recall them quickly for the convenience of the reader. Up to replacing $(\Gamma_k)$ by a subsequence, there exists finite set $S_1$ and a labelling of $\ell_1: E \to S_1$ satisfying the $C'(1/6)$ small cancellation condition, such that $\Gamma$ has no non-trivial label-preserving automorphism. This is proven by Osajda in [39, Theorem 2.7]. However some path may be labelled by some very large powers. Since $\Gamma$ has uniformly bounded degree, it follows from Alon, Grytczuk, Halsućzak and Riordan [4] that there exists a finite set $S_2$ and another labelling of $\ell_2: E \to S_2$ such that no word labelling an embedded path of $\Gamma$ contains a square. One checks easily that for every $n \in \mathbb{N}$, the product labelling $\ell: E \to S_1 \times S_2$ sending an edge $e$ to $(\ell_1(e), \ell_2(e))$ satisfies $C'_n(1/6, 2)$ condition by observing that if $(w_1, w_2)$ is a piece for $\ell$, then $w_1$ is a piece for $\ell_1$. \hfill \square

2.5 A new proof of SQ-universality

**Theorem 2.14 (SQ-universality).** There exists $n_0 \in \mathbb{N}$ such that for every odd exponent $n \geq n_0$, for every set $S$ containing at least two elements, the free Burnside group $B_n(S)$ is SQ-universal in $B_n$.

The following proof builds on a construction used by Gruber in [24, Example 1.13] to show that any countable group embeds in a group of rank 2 defined by a $C'(1/6)$-labelled graph.

**Proof.** Let $n_p$ be the critical exponent given by Theorem 2.4 for $p = 6$. Let $n \geq n_p$ be an odd integer. Let $A$ be a countable group in $B_n$. We fix an epimorphism $F(U) \to A$ where $U$ is an infinite countable set. We will define below a graph $\Gamma_0$ labelled by two letters with the following properties. (Of course it is sufficient to consider the case $|S| = 2$, as any free Burnside group of rank greater than two surjects onto one of rank two.)

(i) The fundamental group of $\Gamma_0$ is isomorphic to the free group on $U$ (i.e. has countably infinite rank).

(ii) The labelling satisfies the $C'_n(1/6, 6)$-assumption.

(iii) The label-preserving automorphism group of $\Gamma_0$ is trivial.

Let $K$ be the kernel of the epimorphism $F(U) \to A$. Let $\Gamma$ be the cover of $\Gamma_0$ corresponding to $K$, i.e. the quotient of the universal cover of $\Gamma_0$ by $K$. The labelling on $\Gamma_0$ induces a labelling on $\Gamma$. The labelling of $\Gamma$ satisfies the $C'_n(1/6, 6)$-assumption: the $C'(1/6)$-condition is argued in [24, Example 1.13]. The labels of paths in $\Gamma$ are exactly the labels of paths in $\Gamma_0$. Hence, if for a cyclically reduced word $w$ we have $w^a$ as label of a path in $\Gamma$, then $w$ labels a closed path in $\Gamma_0$. Since $A$ is $n$-periodic, we deduce that $w^n$ labels a closed path in $\Gamma$. Hence, we may apply Theorem 2.4.
Now $A$ embeds in $G(\Gamma)$ by [24, Example 1.13] as subgroup preserving and acting freely on an embedded copy $\overline{\Gamma}$ in $\mathrm{Cay}(G(\Gamma), S)$ of the labelled graph $\Gamma$. By Theorem 2.4, the canonical projection $f : \mathrm{Cay}(G(\Gamma), S) \to \mathrm{Cay}(G_n(\Gamma), S)$ restricted to $\overline{\Gamma}$ to an isomorphism. If $\pi$ denotes the epimorphism $G(\Gamma) \to G_n(\Gamma)$, then, for any $g \in G(\Gamma)$ and any vertex $v$ of $\mathrm{Cay}(G(\Gamma), S)$, we have $f(gv) = \pi(g)f(v)$. Thus, if $g \in A$ satisfies $\pi(g) = 1$, then, for every $v \in \overline{\Gamma}$: $f(gv) = \pi(g)f(v) = f(v)$, whence $gv = v$ and $g = 1$. Thus $A$ is a subgroup of $G_n(\Gamma)$.

Construction of $\Gamma_0$. We now define a graph $\Gamma_0$ labelled by $\{a, b\}$ satisfying the $C'_1(1/6, 6)$-small cancellation condition, with infinite rank fundamental group and no non-trivial automorphism. In fact, no simple path in $\Gamma_0$ will be labelled by a 6-th power, and any non-simple path labelled by a proper power will be closed.

We first define a sequence $u_k$ of subwords of the Thue-Morse sequence with $3(k-1) < |u_k| < 3k$, and $u_k$ starts and ends with the letter $b$. Take any subword $\hat{u}_k$ of length $3(k-1) + 1$ of the Thue-Morse sequence that starts with $b$. Now, since $a^3$ is not a subword of the Thue-Morse sequence, extending $\hat{u}_k$ by at most two letters yields a word $u_k$ as desired.

Fix $N \geq 10^{10}$. For every $i \in \mathbb{N}$, $i \geq 1$, we let

$$r_i = a^3u_{iN+1}a^3u_{iN+2} \ldots a^3u_{iN+N}.$$  

These are cyclically reduced words by construction. Consider the collection $R = \{r_i \mid i > 0\}$, and consider $\hat{\Gamma}_0$ the disjoint union of cycle graphs $\Lambda_i$ labelled by $r_i$. Note that subwords of cyclic conjugates of elements of $R$ of the form $a^3$ occur exactly in the places written in the definition of the $r_i$ (i.e. they do not occur in any $u_k$ and contain no letters of any $u_k$). Since the $u_k$ have pairwise distinct lengths, this implies that any reduced piece contains at most one subpath labelled by $a^3$. Let $w$ be a piece such that $w$ is a subword of a cyclic conjugate of $r_i$. Then, by our observation, we have $w$ is subword of a word of the form $a^2u_ka^3u_\ell a^2$ for suitable $k, \ell$ and, in particular $|w| \leq 8 + 6(iN + N) = 6(i + 1)N + 8$. On the other hand, we have $|r_i| > 3iN^2 + 3N$. We deduce $|w| < |r_k|/6 - 2$ because $N \geq 10^{10}$.

On $\Lambda_i$, we can read the word $r_i$ starting from some base vertex. Let $v_i$ be the vertex separating $a$ and $a^2$ in the first occurrence of $a^3$ in $r_i$, and $w_i$ be the vertex separating $a$ and $a^2$ in the fourth occurrence of $a^3$. We now build a connected graph $\Gamma_0$ with a reduced labelling by connecting $v_i$ to $w_{i+1}$ by a line graph of length 3 labelled by the word $ba^{-1}b$, for each $i \geq 1$. We call $\Gamma_0$ the resulting graph.

A word is positive if any letter occurring in it occurs with positive exponent. Observe that, when checking pieces in $\Gamma_0$, we only need to check paths labelled by positive words, because any simple closed path is (up to inversion) labelled by a positive word. Now the positive words on $\Gamma_0$ are exactly the word $a$, the positive words read on $\Lambda_i$ for $i \in \mathbb{N}$, and the words obtained from positive words of $\Lambda_i$ by possibly appending a $b$ at the beginning or at the end. Hence, the (relevant) pieces have increased in length by at most 2, and the $C'(1/6)$-condition is still satisfied.

Now, by construction, no word read on a simple path in any of the $\Lambda_i$ for $i \geq 1$ is a 4-th power. We first argue that $\Gamma_0$ does not contain any simple path $\pi$ labelled by a 6-th power: a positive word on $\Gamma_0$ corresponds to a positive word on some $\Lambda_i$ for $i \geq 1$ with possibly a $b$ appended in the beginning or at the end. Hence a positive word cannot contain a 6-th power. Let $\pi$ be labelled by a word that is not positive and whose inverse is not positive and that is a proper power. Then the label of $\pi$ contains, up to inversion, a subword of the form $a^{-1}wa^{-1}$, where $w$ is a positive word.
The two occurrences of $a^{-1}$ correspond to the two line graphs attached to the same $\Lambda_i$ for $i \geq 2$. Thus, $w$ is of the form $vbv$, where $v$ is one of the two labels of simple paths from $v_i$ to $w_i$ in $\Lambda_i$. We already observed that such a path labelled by $v$ is not a piece, i.e. there is a unique path in $\Gamma$ labelled by $v$. Hence, the label of $\pi$ can contain at most one occurrence of $v$, contradicting that it is a proper power.

If a non-simple path is labelled by a proper power of a cyclically reduced word $w$, then we argue that $w$ labels a closed path. Suppose that $\pi$ is a non-simple path whose label is $wp$ for $p > 1$ and $w$ cyclically reduced. As $w$ is cyclically reduced, $\pi$ is reduced, i.e. has no back-tracking. Thus, $\pi$ contains a subpath $\gamma$ that is a simple closed path. Now, because $p > 1$, there exists a subword $u$ of $wp^{-1}$ labelling a subpath of $\gamma$ such that $|u| \geq |\gamma|/2$. (After all, the label of $\gamma$ is a subword of $wp$.) But this and the small cancellation condition imply that $u$ cannot be a piece. Since the property of being a piece goes to subwords, we deduce that $wp^{-1}$ is not a piece. Hence, as $\Gamma_0$ does not admit any non-trivial label-preserving automorphisms by construction, any two paths labelled by $wp^{-1}$ must start from the same vertex. As $\Gamma_0$ contains a path labelled by $wp$, we conclude that $w$ labels a closed path.

## 3 Hyperbolic geometry

Let $X$ be a geodesic metric space. Given two points $x, x' \in X$ we write $|x - x'|_X$, or simply $|x - x'|$, for the distance between them. The Gromov product of three points $x, y, z \in X$ is defined by

$$\langle x, y \rangle_z = \frac{1}{2} \{ |x - z| + |y - z| - |x - y| \}.$$

For the remainder of this section, we assume that the space $X$ is $\delta$-hyperbolic, i.e. for every $x, y, z, t \in X$,

$$\langle x, z \rangle_t \geq \min \{ \langle x, y \rangle_t, \langle y, z \rangle_t \} - \delta. \quad (4)$$

In this article we always assume the hyperbolicity constant $\delta$ is positive. We write $\partial X$ for the Gromov boundary of $X$. Note that we did not assume the space $X$ to be proper, thus we use the boundary defined with sequences converging at infinity [12, Chapitre 2, Définition 1.1]. A major fact of hyperbolic geometry is the stability of quasi-geodesics that we will use in the following form.

**Proposition 3.1.** [13, Corollaries 2.6 and 2.7] Let $l_0 \geq 0$. There exists $L = L(l_0, \delta)$ which only depends on $\delta$ and $l_0$ with the following properties. Let $l \in [0, l_0]$. Let $\gamma: I \to X$ be an $L$-local $(1, l)$-quasi-geodesic.

(i) The path $\gamma$ is a (global) $(2, l)$-quasi-geodesic.

(ii) For every $t, t', s \in I$ with $t \leq s \leq t'$, we have $\langle \gamma(t), \gamma(t') \rangle_{\gamma(s)} \leq l/2 + 5\delta$.

(iii) For every $x \in X$, for every $y, y'$ lying on $\gamma$, we have $d(x, \gamma) \leq \langle y, y' \rangle_x + l + 8\delta$.

(iv) The Hausdorff distance between $\gamma$ and any other $L$-local $(1, l)$-quasi-geodesic joining the same endpoints (possibly in $\partial X$) is at most $2l + 5\delta$. 

**Proposition 3.1.**

Let \( G \) be a group acting by isometries on a hyperbolic space. Moreover, we assume here that the action of \( G \) on \( X \) is WPD and acylindrical action. Let \( N, L, d \in \mathbb{R}^*_+ \). The group \( G \) acts \((d, L, N)\)-acylindrically on \( X \) if the following holds: for every \( x, y \in X \) with \( |x - y| \geq L \), the number of elements \( u \in G \) satisfying \( |ux - x| \leq d \) and \( |uy - y| \leq d \) is bounded above by \( N \). The group \( G \) acts acylindrically on \( X \) if for every \( d > 0 \) there exist \( N, L > 0 \) such that \( G \) acts \((d, L, N)\)-acylindrically on \( X \).

If the action of \( G \) on \( X \) is acylindrical then it is also WPD. Since \( X \) is a hyperbolic space, one can decide whether an action is acylindrical by looking at a single value of \( d \).

**Proposition 3.5** (Dahmani-Guirardel-Osin [15, Proposition 5.31]). The action of \( G \) on \( X \) is acylindrical if and only if there exists \( N, L > 0 \) such that the action is \((100\delta, L, N)\)-acylindrical.

**Remark.** F. Dahmani, V. Guirardel and D. Osin work in a class of geodesic spaces. Nevertheless, following the proof of [15, Proposition 5.31] one observes that the statement also holds for length spaces. Moreover one gets the following quantitative statement. Assume that the action of \( G \) on \( X \) is \((100\delta, L, N)\)-acylindrical, then for every \( d > 0 \) the action is \((d, L(d), N(d))\)-acylindrical where

\[
L(d) = L + 4d + 100\delta, \\
N(d) = \left( \frac{d}{3\delta} + 3 \right) N.
\]

**Classification of group actions.** We assume here that the action of \( G \) on \( X \) is WPD. We denote by \( \partial G \) the set of all accumulation points of an orbit \( G \cdot x \) in the boundary \( \partial X \). This set does not depend on the point \( x \). One says that the action of \( G \) on \( X \) is
Hyperbolic geometry

- elliptic, if \( \partial G \) is empty, or equivalently if one (hence any) orbit of \( G \) is bounded;
- parabolic, if \( \partial G \) contains exactly one point;
- lineal, if \( \partial G \) contains exactly two points;

If the action of \( G \) is elliptic, parabolic or lineal, we will say that this action is elementary. In this context, being elliptic (respectively parabolic, lineal, etc) refers to the action of \( G \) on \( X \). However, if there is no ambiguity we will simply say that \( G \) is elliptic (respectively parabolic, lineal, etc). If \( g \) is a loxodromic element of \( G \), we write \( g^- \) and \( g^+ \) for the repulsive and attractive points of \( g \) in \( \partial X \). The subgroup \( E^+(g) \) of \( G \) fixing point-wise \( \{ g^-, g^+ \} \) is a lineal subgroup. The set \( F \) of all elliptic elements of \( E^+(g) \) forms a normal subgroup of \( E^+(g)/F \) isomorphic to \( \mathbb{Z} \). We say that \( g \) is primitive if its image in \( E^+(g)/F \) is \( \pm 1 \).

3.2 Invariants of a group action.

In this section we recall several numerical invariants associated to a WPD action. They will be useful to control the value of the critical exponent \( n_p \) in Theorems 2.4 and 2.8.

Exponent of the holomorph. Let \( F \) be a finite group. Its holomorph, denoted by \( \text{Hol}(F) \), is the semi-direct product \( F \rtimes \text{Aut}(F) \), where \( \text{Aut}(F) \) stands for the automorphism group of \( F \). The exponent of \( \text{Hol}(F) \) is the smallest integer \( n \) such that \( \text{Hol}(F) \) belongs to \( \mathfrak{B}_n \). Assume now that the action of \( G \) on \( X \) is WPD. It is known that every lineal subgroup \( E \) of \( G \) is virtually cyclic. In particular, it admits a maximal finite normal subgroup \( F \) and \( E/F \) is isomorphic either to \( \mathbb{Z} \) of the infinite dihedral group \( D_\infty \); see for instance [14, Corollary 3.30].

Definition 3.6. The integer \( e(G,X) \) is the least common multiple of the exponents of \( \text{Hol}(F) \), where \( F \) runs over the maximal finite normal subgroups of all maximal lineal subgroups of \( G \).

Remark 3.7. If the lineal subgroups of \( G \) are all cyclic then \( e(G,X) = 1 \).

Injectivity radius. To measure the action of an element \( g \in G \) on \( X \) we define the translation length and the asymptotic translation length as

\[
[g]_X = \inf_{x \in X} |gx - x|, \quad \text{and} \quad [g]_X^\infty = \lim_{n \to +\infty} \frac{1}{n} |g^n x - x|.
\]

These two lengths are related as follows [12, Chapitre 10, Proposition 6.4].

\[
[g]_X^\infty \leq [g]_X \leq [g]_X^\infty + 16\delta. \tag{5}
\]

Definition 3.8 (Injectivity radius). The injectivity radius of \( G \) on \( X \) denoted by \( \text{inj}(G,X) \) is the infimum of \( [g]_X^\infty \) over all loxodromic elements \( g \in G \).

Lemma 3.9 (Bowditch [10, Lemma 2.2]). Let \( L, N > 0 \). Assume that the action of \( G \) on \( X \) is \((100\delta, L, N)\)-acylindrical. Then the injectivity radius of \( G \) on \( X \) is bounded below by

\[
\text{inj}(G,X) \geq \delta/N
\]
Remark. Although he does not provide a precise estimate, B. Bowditch already stresses in his proof that the lower bound only depend on $\delta$, $N$ and $L$. For the agreement of the reader we compute this lower bound.

Proof. According to Proposition 3.5, the action of $G$ on $X$ is $(200\delta, L', N')$-acylindrical where $L' = L + 900\delta$ and $N' = 50N$. Let $g$ be a loxodromic element of $G$. According to (5), it is sufficient to prove that $[g^N] \geq 66\delta$. Assume on the contrary that it is false. There exists an $L'\delta$-local $(1, \delta)$-quasi-geodesic $\gamma : \mathbb{R} \to X$ joining $g^-$ to $g^+$ [14, Lemma 3.2]. Let $x$ and $y$ be two points on $\gamma$ such that $|x - y| \geq L'$. Let $j \in \{0, \ldots, N'\}$. We know that $\gamma$ is contained in the $52\delta$-neighbourhood of the axis of $g^j$ [13, Lemma 2.32] hence $|g^j x - x| \leq [g^j] + 112\delta$. It follows from (5) that

$$|g^j x - x| \leq [g^j] + 112\delta \leq j[g]^\infty + 128\delta \leq N'[g]^\infty + 128\delta \leq [g^{N'}] + 128\delta \leq 200\delta.$$ 

The same observation holds with $y$. It follows from the acylindricity that the set $\{1, g, g^2, \ldots, g^{N'}\}$ contains at most $N'$ elements. Hence $g$ has finite order, which contradicts our assumption. \qed

The invariants $\nu$ and $A$. The critical exponent $n_p$ that appears in Theorems 2.4 and 2.8 will depend on two more numerical invariants that are defined as follows.

Definition 3.10. The invariant $\nu(G, X)$ (or simply $\nu$) is the smallest positive integer $m$ satisfying the following property. Let $g$ and $h$ be two isometries of $G$ with $h$ loxodromic. If $g, h^{-m}gh, \ldots, h^{-m}gh^m$ generate an elementary subgroup which is not loxodromic then $g$ and $h$ generate an elementary subgroup of $G$.

To any element $g \in G$, we associate to $g$ an axis $A_g$ defined as the set of points $x \in X$ such that $|gx - x| < |g| + 8\delta$. Given $\alpha \in \mathbb{R}_+$, we write $A_\alpha^g$ for its $\alpha$-neighborhood. If $g_0, \ldots, g_m$ are $m$ elements of $G$ we denote by $A(g_0, \ldots, g_m)$ the quantity

$$A(g_0, \ldots, g_m) = \text{diam} \left( A_{g_0}^{+13\delta} \cap \ldots \cap A_{g_m}^{+13\delta} \right).$$

Recall that the parameter $L_S$ is the constant given by the stability of quasi-geodesics (Definition 3.2).

Definition 3.11. Assume that $\nu = \nu(G, X)$ is finite. We denote by $\mathcal{A}$ the set of $(\nu + 1)$-uples $(g_0, \ldots, g_\nu)$ such that $g_0, \ldots, g_\nu$ generate a non-elementary subgroup of $G$ and for all $j \in \{0, \ldots, \nu\}$, $[g_j] \leq L_S\delta$. The parameter $A(G, X)$ is given by

$$A(G, X) = \sup_{(g_0, \ldots, g_\nu) \in \mathcal{A}} A(g_0, \ldots, g_\nu).$$

Lemma 3.12 (Coulon [14, Lemmas 6.12 – 6.14]). Let $L, N > 0$. Assume that the action of $G$ on $X$ is $(100\delta, L, N)$-acylindrical. Then the invariants $\nu(G, X)$ and $A(G, X)$ are bounded above as follows

$$\nu(G, X) \leq N \left( 2 + \frac{L}{\delta} \right) \quad \text{and} \quad A(G, X) \leq 10L^2S^3(L + 5\delta).$$

Remark. The statements given in [14] do not mention an explicit upper bound for $\nu(G, X)$ and $A(G, X)$. However following the proofs yields directly to the result. Our estimates are very generous. The important point to notice is that they only depend on $\delta$, $L$ and $N$. 
4 From acylindrical action to periodic quotient

In this section we proof the following fact. If a group $G$ admits a non-elementary acylindrical action on a hyperbolic space $X$ then one can exploit the negative curvature of $X$ to a produce a (partially) periodic quotient of $G$. A precise statement is given in Proposition 4.1 below. We want to stress the fact that the critical exponent $n_p$ appearing in Proposition 4.1 only depends on the parameters of the action and not on the group $G$ or the space $X$.

**Proposition 4.1** (compare with Coulon [14, Theorem 6.15]). Let $N, L, \delta, r > 0$. There exists $N_1 \in \mathbb{N}$ such that the following holds. Let $G$ be a group acting $(100\delta, L, N)$-acylindrically on a $\delta$-hyperbolic length space $X$. We assume that $G$ is non-elementary, has no even torsion and $e(G, X)$ is odd. For every odd integer $n \geq N_1$ that is a multiple of $e(G, X)$, there exists a quotient $B_n$ of $G$ with the following properties.

(i) Every elliptic subgroup of $G$ embeds in $B_n$.

(ii) For every $b \in B_n$ that is not the image of an elliptic element we have $b^n = 1$.

(iii) If every elliptic subgroup of $G$ belongs $\mathfrak{B}_n$ then $B_n$ is isomorphic to $G/G^n$. In particular $B_n$ lies in $\mathfrak{B}_n$.

(iv) There exist infinitely many elements in $B_n$ which are not the image of an elliptic element of $G$.

(v) For every $g \in G \setminus \{1\}$, for every $x \in X$, if $|gx - x| \leq r$, then the image of $g$ in $B_n$ is not trivial.

**Remark 4.2.** In [2], S.I. Adian introduced a notion of free product in the class $\mathfrak{B}_n$. Our result can be used to recover most of its properties. Let $n$ be an odd integer. Consider $A$ and $B$ two groups of exponent $n$. It follows from the Bass-Serre theory that the (regular) free product $G = A \ast B$ acts $(0, 1, 0)$-acylindrically on the corresponding Bass-Serre tree $X$, which is a 0-hyperbolic space. Provided $n$ is large enough (this value does not depend on $A$ or $B$) one can apply Proposition 4.1 to $G$ and $X$. We get as output a group of exponent $n$, denoted by $A \ast^n B$, in which $A$ and $B$ embeds. Moreover if $H$ is a group of $\mathfrak{B}_n$ containing $A$ and $B$ and generated by these two subgroups, then $H$ is a quotient of $A \ast^n B$. In this article we always assumed that the hyperbolicity constant $\delta$ is positive. Nevertheless this is not an issue as we may look at the Bass-Serre tree as a $\delta$-hyperbolic space for arbitrarily small positive $\delta$.

The proof of Proposition 4.1 is essentially done by the first author in [14, Theorem 6.15]. However the statement there does not make the dependency between $N_1$ and all the other parameters explicit. For the agreement of the reader we recall the main steps of the proof, focusing on the ones which are crucial for the control of $N_1$. The main ideas are the following. One defines by induction a sequence of quotients

$$G = G_0 \rightarrow G_1 \rightarrow \cdots \rightarrow G_k \rightarrow G_{k+1} \rightarrow \cdots$$

where $G_{k+1}$ is obtained from $G_k$ by adding new relations of the form $h^n$ with $h$ running over all small loxodromic elements of $G_k$. The quotient $B_n$ is then the direct limit of these groups. The difficulty is to control the geometry of $G_k$ at each step to make sure that the sequence of groups does not ultimately collapse. This is the role of the next statement that will be used as the induction step in our process.
**Proposition 4.3** (Coulon [14, Proposition 6.1]). There exist positive constants $\delta_1, A_0, r_0, \alpha$ such that for every positive integer $\nu_0$ there is an integer $N_0$ with the following properties. Let $G$ be a group without involution acting by isometries on a $\delta_1$-hyperbolic length space $X$. We assume that this action is WPD, non-elementary and without parabolic. Let $N_1 \geq N_0$ and $n \geq N_1$ be an odd integer. Let $K$ be the (normal) subgroup of $G$ generated by $\{h^n, h \in P\}$ and $\bar{G}$ the quotient of $G$ by $K$. We make the following assumptions.

(i) $e(G, X)$ divides $n$.

(ii) $\nu(G, X) \leq \nu_0$.

(iii) $A(G, X) \leq \nu_0 A_0$.

(iv) $r_{mj} (G, X) \geq r_0 / \sqrt{N_1}$.

Then there exists a $\delta_1$-hyperbolic length space $\bar{X}$ on which $\bar{G}$ acts by isometries. This action is WPD, non-elementary and without parabolic. The group $\bar{G}$ has no involution. Moreover it satisfies Assumptions (i)-(iv).

**Vocabulary.** Let $n \geq N_1$ be two integers as in the proposition above. Let $G$ be a group acting by isometries on a metric space $X$. We say that $(G, X)$ satisfies the induction hypotheses for exponent $n$ if it satisfies the assumptions of Proposition 4.3, including Points (i)-(iv).

**Proof of Proposition 4.1.** The parameters $\delta_1, A_0, r_0$ and $\alpha$ are the universal constants given by Proposition 4.3. Recall that the action of $G$ on $X$ is non-elementary and $(100\delta, L, N)$-acylindrical. We fix $\nu_0 = N(2 + L/\delta)$. The critical exponent $N_0 \in \mathbb{N}$ is the one provided by Proposition 4.3. We define a rescaling parameter $a > 0$ as follows

$$a = \min \left\{ \frac{\delta_1}{\delta}, \frac{\nu_0 A_0}{10L^2 S_3 N^3(L + 5\delta)}, \frac{L_3 \delta_1}{r} \right\}$$

We now choose $N_1 \geq N_0$ such that

$$\frac{a \delta}{N} \geq \frac{r_0}{\sqrt{N_1}} \quad \text{and} \quad \frac{\alpha}{\sqrt{N_1}} < 1.$$  

(7)

Observe that $a$ and thus $N_1$ only depend on $\delta$, $L$, $N$ and $r$. From now on, we fix an odd integer $n \geq N_1$ which is a multiple of $e(G, X)$. 

The base of induction. We denote by \( X_0 = aX \) the space \( X \) rescaled by \( a \), i.e. for every \( x, x' \in X_0 \), we have \( |x - x'|_{X_0} = a|x - x'|_X \). In addition we let \( G_0 = G \). One checks that the action of \( G_0 \) on \( X_0 \) is \((100a\delta, aL, N)\)-acylindrical. According to Lemma 3.9 and Lemma 3.12 we have
\[
\text{inj} (G_0, X_0) \geq \frac{a\delta}{N}, \quad \nu(G_0, X_0) \leq N \left( 2 + \frac{L}{\delta} \right) \quad \text{and} \quad A(G_0, X_0) \leq 10L^2N^3a(L + 5\delta)
\]
It follows from our choice of \( a \) and \( N_1 \) that \( X_0 \) is \( \delta_1 \)-hyperbolic, \( \nu(G_0, X_0) \leq \nu_0 \), \( A(G_0, X_0) \leq \nu_0A_0 \) [13, Lemma 2.45] and \( \text{inj} (G_0, X_0) \geq r_0/\sqrt{N_1} \). In other words, \((G_0, X_0)\) satisfies the induction hypotheses for exponent \( n \).

The inductive step. Let \( k \in \mathbb{N} \). We assume that we already constructed the group \( G_k \) and the space \( X_k \) such that \((G_k, X_k)\) satisfies the induction hypotheses for exponent \( n \). We denote by \( P_k \) the set of primitive loxodromic elements \( h \in G_k \) such that \([h]_{X_k} \leq L_S\delta_1 \). Let \( K_k \) be the (normal) subgroup of \( G_k \) generated by \( \{h^n, h \in P_k \} \). We write \( G_{k+1} \) for the quotient of \( G_k \) by \( K_k \). By Proposition 4.3, there exists a metric space \( X_{k+1} \) such that \((G_{k+1}, X_{k+1})\) satisfies the induction hypotheses for exponent \( n \). Moreover the projection \( G_k \to G_{k+1} \) fulfills the properties (P1)-(P4) of Proposition 4.3.

Direct limit. The direct limit of the sequence \((G_k)\) is a quotient \( B_n \) of \( G \). We claim that this group satisfies the announced properties. Following the same strategy than in [14, Theorem 6.9] we prove the following statements: every elliptic subgroup of \( G \) embeds into \( B_n \); every element \( b \in B_n \) which is not the image of an elliptic element of \( G \) satisfies \( b^n = 1 \); there are infinitely many elements in \( B_n \) which are not the image of an elliptic element of \( G \). So we are left to prove Points (iii) and (v).

We start with Point (iii). Assume that every elliptic subgroup of \( G \) has exponent \( n \). It follows from the previous discussion that for every \( b \in B_n \), \( b^n = 1 \). Hence the projection \( G \to B_n \) induces an epimorphism \( G/G^n \to B_n \). On the other hand, all the relations added to define \( B_n \) are \( n \)-th power. In other words the kernel \( K \) of the projection \( G \to B_n \) is contained in \( G^n \). Hence \( G/G^n \) and \( B_n \) are isomorphic.

We finish with Point (v). Let \( g \in G \setminus \{1\} \) and \( x \in X \) such that \( |gx - x|_X \leq r \). It follows from our choice of \( a \) that \( |gx - x|_{X_0} \leq L_S\delta_1 \). In particular \( [g]_{X_0} \leq L_S\delta \). If \( g \) is elliptic in \( G \), then (P4) tells us that the image of \( g \) in \( G_1 \) is a non-trivial elliptic element. If \( g \) is loxodromic in \( G \), then by construction the image of \( g \) in \( G_1 \) is elliptic. Moreover this image is non-trivial [14, Theorem 5.2(4)]. A proof by induction using (P1) and (P4) now shows that for every \( k \in \mathbb{N} \), the image of \( g \) in \( G_k \) is non trivial. Hence neither is its image in \( B_n \).

5 From small cancellation to acylindrical action

In this section we study the action of a graphical small cancellation group on its hyperbolic cone-off space, see Definition 5.8. We first provide definitions and notations and then show that, in the cases we consider, the action is acylindrical with universal constants. We then proceed to determine the elliptic elements and the maximal elementary subgroups for this action. Finally, we prove a result that will justify our concise statement of Theorem 2.4.
5.1 Definitions and notation

Recall the definitions of small cancellation conditions given in Section 2.1. We shall often use the word "piece" to mean either a word as defined in Section 2.1, or as a path (in a labelled graph) whose label is a piece in that sense.

We first discuss graphical small cancellation over the free group. We give a slight generalization of the definition for graphical small cancellation over free groups Definition 2.3 that will turn out to be suitable for proving acylindricity of the action on the hyperbolic cone-off space.

Definition 5.1. Let \( p \in \mathbb{N} \) and \( \lambda \in (0,1) \). Let \( \Gamma \) be a graph labelled by a set \( S \). We say that \( \Gamma \) satisfies the \( C'(\lambda,p) \)-small cancellation assumption if the following holds.

(i) \( \Gamma \) satisfies the \( C'(\lambda) \)-condition.

(ii) Whenever \( w \) is a cyclically reduced word such that \( w^p \) labels a path in \( \Gamma \), then for every \( n \in \mathbb{N} \), the word \( w^n \) labels a path in \( \Gamma \).

The following definitions will enable us to do small cancellation theory that produces quotients of a given free product of groups \( \ast_{i \in I} G_i \). We recall the definition of graphical small cancellation over free products of Gruber [23]. Given a graph \( \Gamma \) labelled by a set \( S \), the reduction of \( \Gamma \) is the quotient of \( \Gamma \) by the following equivalence relation on the edges of \( \Gamma \): \( e \sim e' \) if and only if \( \ell(e) = \ell(e') \), and there exists a path from \( ie \) to \( ie' \) whose label is trivial in \( F(S) \). Here, and henceforth, \( \ell(e) \) denotes the label in \( S \cup S^{-1} \) of an edge \( e \).

Definition 5.2 (Completion). Let \( \Gamma \) be a graph labelled by a set \( S := \sqcup_{i \in I} S_i \), where each \( S_i \) is a generating set of a group \( G_i \). The completion \( \overline{\Gamma} \) of \( \Gamma \) is defined as the reduction of the graph obtained from \( \Gamma \) by performing the following operations.

- onto each edge labelled by \( s \in S_i \) for some \( i \), attach a copy of \( \text{Cay}(G_i,S_i) \) along an edge labelled by \( s \);
- if, for some \( i \), no element of \( S_i \) occurs as a label of \( \Gamma \), then add a copy of \( \text{Cay}(G_i,S_i) \) (as its own connected component).

A word in the free monoid on \( S \cup S^{-1} \) is locally geodesic if it labels a geodesic in \( \text{Cay}(\ast_{i \in I} G_i,S) \), and a path in \( \overline{\Gamma} \) (or another \( S \)-labelled graph) is locally geodesic if its label is locally geodesic.

Definition 5.3 (Small cancellation condition). Let \( \lambda \in (0,1) \). Let \( \Gamma \) be a graph labelled by a set \( S := \sqcup_{i \in I} S_i \), where each \( S_i \) is a generating set of a group \( G_i \). We say \( \Gamma \) satisfies the \( C'_*(\lambda) \)-condition if

- \( \Gamma = \overline{\Gamma} \);
- every \( \text{Cay}(G_i,S_i) \) is an embedded subgraph of \( \Gamma \);
- for every locally geodesic piece \( w \) that is a subword of the label of a simple closed path \( \gamma \) in \( \Gamma \) such that the label of \( \gamma \) is non-trivial in \( \ast_{i \in I} G_i \), we have \( |w| < \lambda |\gamma| \).

Here, as usual, \(| \cdot |\) denotes the (edge-)length of a path, respectively the length of a word (i.e. its number of letters). We call the embedded copies of \( \text{Cay}(G_i,S_i) \) attached Cayley graphs. When we say an \( S \)-labelled graph satisfies the \( C'_*(\lambda) \)-condition, we shall assume that we have \( S = \sqcup_{i \in I} S_i \) for given generating sets \( S_i \) of given groups \( G_i \). If \( \Gamma = \overline{\Gamma} \), the group \( G(\Gamma) \), using our previous definition in Section 2.2, coincides with the quotient of \( \ast_{i \in I} G_i \) by all the words read on closed paths in \( \Gamma \).
The assumption $\Gamma = \Gamma$ is a mere technicality to allow for efficient notation. We recall from [23] that if $\Gamma$ satisfies the $C'_*(1/6)$-condition, then each generating factor $G_i$ is subgroup of $G(\Gamma)$, and each component of $\Gamma$ injects into $\text{Cay}(G(\Gamma), S)$.

Note that the case that $\Gamma$ can be realized as the completion of a disjoint union of cycle graphs and that $S_i = G_i$ recovers the classical $C'_*(\lambda)$-condition, whose power-free simplification is given in Definition 2.6.

In order to prove our acylindricity statement also in the free product case, we require the following property for $\Gamma$. It will be used in Lemma 5.30.

**Definition 5.4** (Cylinder-free). Let $\Gamma$ satisfy the $C'_*(\lambda)$-condition for some $\lambda$. We say $\Gamma$ is cylinder-free if for every connected component $\Gamma_0$ and every two disjoint attached Cayley graphs $C_1$ and $C_2$ of $\Gamma_0$, any label-preserving automorphism $\varphi$ of $\Gamma_0$ with $\varphi(C_1) = C_1$ and $\varphi(C_2) = C_2$ is the identity.

**Remark 5.5.** Let $\Gamma$ satisfy the $C'_*(\lambda)$-condition for some $\lambda$, and assume $\Gamma$ is the completion of a disjoint union of cycle graphs. Let $\Gamma_0$ be a connected component of $\Gamma$ and $C$ an attached Cayley graph in $\Gamma_0$. Then there are at most two vertices $v_1$ and $v_2$ that $C$ shares with other attached Cayley graphs. A label-preserving automorphism $\varphi$ of $\Gamma_0$ that preserves $C$ also preserves the set \{v_1, v_2\}. As $\varphi$ is uniquely determined by the image of any one vertex, this means that there are at most two options for $\varphi$: being the identity, and permuting $v_1$ and $v_2$. In particular, the order of $\varphi$ divides 2.

We also observe: if an automorphism $\varphi$ of $\Gamma_0$ preserves an attached $C = \text{Cay}(G_i, S_i)$, then the action of $\varphi$ on $C$ corresponds to left-multiplication with the element of $G_i$ represented by the label of any path in $C$ from $v$ to $\varphi(v)$ for any vertex $v$ in $C$. Thus, the order of $\varphi$ equals the order of an element of $G_i$. In particular, if $\Gamma$ is the completion of a disjoint union of cycle graphs and no generating factor has even torsion, then $\Gamma$ is cylinder-free.

**Example 5.6.** A classical $C'_*(1/6)$-presentation that is not cylinder-free is given, for example, by the quotient of $\mathbb{Z} \ast \mathbb{Z} \ast \mathbb{Z} \ast \mathbb{Z}/2\mathbb{Z}$, where each copy $G_i$ of $\mathbb{Z}$ is generated by $t_i$, $i = 1, 2, 3$, and $\mathbb{Z}/2\mathbb{Z}$ is generated by $s$, by the relation $t_1t_2t_3s^{s_2}t_3^{-1}t_2^{-1}t_1^{-1}t_3^{-1}s^{s_2}$, where $s_1, s_2 \in \{1, -1\}$, and hence have length 8. All pieces have length at most 1 (observe, e.g. that by the above considerations, the paths labelled by $t_1t_2t_3$ are not pieces). Thus, the $C'_*(1/8 + \varepsilon)$-condition is satisfied for any $\varepsilon > 0$.

**Definition 5.7.** Let $\lambda \in (0, 1)$, let $p \in \mathbb{N}$. Let $\Gamma$ be a graph labelled by a set $S := \sqcup_{i \in I} S_i$, where each $S_i$ is a generating set of a group $G_i$. We say $\Gamma$ satisfies the $C'_*(\lambda, p)$-condition if

(i) it satisfies the $C'_*(\lambda)$-condition;

(ii) for every cyclically reduced word $w$ over the alphabet $S$, if $w^p$ is the label of a path in $\Gamma$, the for every $n \in \mathbb{N}$, there is a path in $\Gamma$ labelled by $w^n$;

(iii) it is cylinder-free.

We have argued in Remark 5.5 that a presentation satisfying the power-free $C'_*(\lambda, p)$-condition of Definition 2.6 and for which no generating factor contains elements of order two can be regarded as satisfying the (graphical) $C'_*(\lambda, p)$-condition we just defined.
The hyperbolic cone-off space $\hat{X}$. Let $\Gamma$ be a graph labelled be a set $S$. We associate to $\Gamma$ its cone-off space defined by Gruber and Sisto [25].

**Definition 5.8** (The cone-off space). Let $\Gamma$ be a graph labelled by $S$. The cone-off space, denoted by $X(\Gamma)$ (or simply $\hat{X}$) is the Cayley graph of $G(\Gamma)$ with respect to $S \cup W$, where $W$ stands for the set of all elements of $G(\Gamma)$ represented by the label of a path in $\Gamma$.

Observe that in the free product case, if $\Gamma$ is its own completion (as is the case for a $C'_*(\lambda)$-graph) then the image in $G(\Gamma)$ of each one of the generating factors is contained in $W$. We record an immediate consequence of [25, Remark 4.11]:

**Theorem 5.9** (Uniform hyperbolicity of $\hat{X}$). Let $\Gamma$ be a $C'(1/6)$-labelled graph or a $C'_*(1/6)$-labelled graph. Then the vertex set of any geodesic triangle in $\hat{X}$ is 5-slim.

In particular, the vertex set of $\hat{X}$ is 40-hyperbolic in the sense of Section 3 by [12, Chapitre 1, Proposition 3.6].

In the following, we will show results concerning quotients of free groups and quotients of free products, which are, in principle, separate cases, whence we have to carry out two proofs. However, we shall see that the geometric arguments involved in both proofs are very similar and, in many cases, exactly the same. We now introduce standing assumptions and notation that will let us efficiently handle the two cases in parallel.

**Notation.** We denote by $\Gamma$ a labelled graph and by $S$ the set of labels. Recall our convention that if we say $\Gamma$ satisfies the $C'_*(\lambda)$-condition, then we assume $S = \sqcup_{i \in I} S_i$, where the $S_i$ are generating sets of groups $G_i$. We denote $X := \text{Cay}(G(\Gamma), S)$ and $\hat{X}$ the cone-off space from Definition 5.8. We will consider $X$ as a subgraph of $\hat{X}$.

We from now on assume that, in the free case, the $C'(1/6)$-condition is satisfied and, in the free product case, the $C'_*(1/6)$-condition is satisfied. Moreover, for simplicity, we assume that no component of $\Gamma$ is a single vertex, and that every generator occurs on some edge of $\Gamma$. (The latter is no restriction: in the free product case, it follows from the definition of $\Gamma$. In the free case we may just add, for any generator that does not occur already, a new component to $\Gamma$ that is merely an edge labelled by the generator. This does not change the metric on the vertex set of $\hat{X}$.)

A relator is the image of component of $\Gamma$ in $X$ under a label-preserving graph homomorphism. Note that such a relator is in fact an (isometrically) embedded image of a component [35, 22, 25].

We denote by $F$ the free group on $S$ in the free case, respectively the free product of the generating factors $G_i$ in the free product case.

**$F$-reduced paths.** In the free product case, we define the following terminology, which should be thought of as a way of dealing with homotopy classes of paths not necessarily in a tree (which corresponds to the free group case) but in a tree of Cayley complexes (which corresponds to the free product case).

We say a path in $X$ is $F$-reduced if its label has the form $w_1 w_2 \ldots w_k$, where each $w_i$ is a word contained in a single generating factor that does not represent the identity, and any two consecutive $w_i$ come from distinct generating factors. (In other words, if $w_i$ represents an element $g_i$ of a generating factor, then $g_1 g_2 \cdots g_k$ is in normal form in the sense of Section 2.2.) A closed path is cyclically $F$-reduced if every one of its cyclic shifts is $F$-reduced. (In other words, $g_1 g_2 \cdots g_k$ is weakly cyclically reduced.) We say two paths are $F$-equivalent if they have the same starting vertex and have the same label as element of $F$. A path is $F$-homotopically trivial if its label is
trivial in $F$. An $F$-tree is a subgraph of $X$ where every two vertices are connected by a unique $F$-equivalence class of $F$-reduced paths or, equivalently, a connected subgraph where any closed path is $F$-homotopically trivial. Given an $F$-reduced path $p$, an $F$-subpath $q$ is an $F$-reduced path $F$-equivalent to a subpath of $p$ such that the label $\ell(q)$ of $q$ is a subword of $\ell(p)$ in the free product sense. This means: if the element of $F$ represented by $\ell(p)$ is written as $g_1g_2\ldots g_k$ in normal form, then there exist $1 \leq i \leq j \leq k$ such that $p$ may be written as $p_1p_2p_3$ with $\ell(p_1)$ representing $g_1g_2\ldots g_{i-1}$, $\ell(p_2)$ representing $g_i g_{i+1}\ldots g_j$, and $q$ being $F$-equivalent to $p_2$.

We have already explained the notion of locally geodesic paths in the free product setting. In the free group case, we shall take locally geodesic to mean reduced (i.e. without back-tracking).

In the free group case, all terms defined above are defined in the free group case by simply omitting the prefix “$F$−” (i.e. an $F$-reduced path is simply a reduced path, a an $F$-tree is simply a tree, . . .). Using the same words for both cases will allow us to streamline statements.

5.2 Acylindricity of the action on $\hat{X}$

We set out to prove the following result. Notice that the constants we produce are universal, i.e. independent of the specific graph $\Gamma$ under consideration.

**Theorem 5.10** (Acylindricity theorem). For all $p \in \mathbb{N}$ and $\varepsilon \geq 0$ there exist $L > 0$ and $N \in \mathbb{N}$ with the following property. Let $\Gamma$ be a labelled graph satisfying the graphical $C'(1/6,p)$-condition or the graphical $C'_\varepsilon(1/6,p)$ condition. Then the action of $G(\Gamma)$ on the cone-off space $\hat{X}$ is $(\varepsilon, L, N)$-acylindrical.

The actual constants we obtain are $L = 18\varepsilon + 25$ and $N = (9\varepsilon + 4)^3(8p + 100)$, i.e. $L$ does not depend on $p$, while $N$ does.

**Remark 5.11.** When considering the action of $G(\Gamma)$ on $\hat{X}$, one may instead consider the action of $G(\Gamma)$ on the graph $R$ with vertex set $\{\text{relators in } X\}$ and where any two vertices are connected by an edge if their corresponding relators in $X$ intersect. The graph $R$ comes with the $G(\Gamma)$-action induced by the action of $G(\Gamma)$ on $X$, and $R$ is $G(\Gamma)$-equivariantly $(1,1)$-quasi-isometric to $\hat{X}$. (Recall here that we assume that every generator occurs on $\Gamma$.) The two main propositions in our proof of Theorem 5.10, namely Propositions 5.19 and 5.28, are phrased purely in terms of $R$, as are many of our intermediate results. Nonetheless, we will often need the underlying space $\hat{X}$ in our arguments.

5.2.1 Convexity of geodesics in $\hat{X}$

In this subsection, we link the metric properties of geodesics in $\hat{X}$ to metric properties of $X$, strengthening [25, Proposition 3.6]. We remark here that Lemmas 5.13 and 5.17 are our only applications of van Kampen diagrams in the proof of Theorem 5.10. While more extensive usage of diagrams (following techniques of [25, 5]) would be able to provide better acylindricity constants, limiting their usage enables us to more clearly present our proof, in particular in view of the dual approach to both free group and free product cases.

We recall a tool from graphical small cancellation theory and basic facts about it, see [22, 23] for details.

**$\Gamma$-reduced diagrams.** A diagram over a presentation $\langle S \mid R \rangle$ is a finite connected $S$-labelled graph $D$ with a fixed embedding in $\mathbb{R}^2$, such that each bounded region (face) has a boundary word.
in \( R \). Given a closed path \( \gamma \) in \( \text{Cay}(G, S) \), where \( G \) is the group defined by \( \langle S \mid R \rangle \), a diagram for \( \gamma \) is a diagram that admits a label-preserving map \( \partial D \to \gamma \), where \( \partial D \) is the boundary of the unbounded component defined by \( D \) inside \( \mathbb{R}^2 \). It is a classical fact that for every closed path in \( \text{Cay}(G, S) \) there exists a diagram. To simplify notation, we will often not distinguish in notation between subpaths of \( \gamma \) and their preimages in \( \partial D \) where this does not cause ambiguity. A disk diagram is a diagram without cut-vertices.

Suppose we have an \( S \)-labelled graph \( \Gamma \) and the presentation \( \langle S \mid \text{labels of simple closed paths in } \Gamma \rangle \). A diagram \( D \) over \( \Gamma \) is a diagram over this presentation. If \( \Pi \) is a face of \( D \), then \( \partial \Pi \) admits a map \( \partial \Pi \to \Gamma \) (possibly more than one), which we call lift. We say \( D \) is \( \Gamma \)-reduced if for any two faces \( \Pi \) and \( \Pi' \) and any path \( a \) in \( \Pi \cap \Pi' \), no two lifts \( \partial \Pi \to \Gamma \) and \( \partial \Pi' \to \Gamma \) restrict to the same map on \( a \) and any path \( a \) in \( \Pi \cap \Pi' \) is locally geodesic. In the free product case, we also require that any face whose boundary word is trivial in \( F \) actually has a boundary word that is contained in a single generating factor.

If \( \Gamma \) satisfies the \( C'(1/6) \)-condition or the \( C'_4(1/6) \)-condition, then any closed path \( \gamma \) in \( \text{Cay}(G(\Gamma), S) \) admits a \( \Gamma \)-reduced diagram \( D \) over \( \Gamma \). In a \( \Gamma \)-reduced diagram, any face is simply connected, and for any two faces \( \Pi \) and \( \Pi' \) and any path \( \alpha \) in \( \Pi \cap \Pi' \) we have \( |\alpha| < \min\{|\partial \Pi|, |\partial \Pi'|\}/6 \), because \( \alpha \) is a locally geodesic piece. Finally, we have that every face that intersects at least one other face in at least one edge has a label that is non-trivial in \( F \).

An arc in a diagram is an embedded line graph whose endpoints have degrees different from 2 and all whose other vertices have degree 2. Given a face \( \Pi \), \( d(\Pi) \) is the number of arcs in \( \partial \Pi \), \( i(\Pi) \) is the number of arcs in \( \partial \Pi \) that \( \Pi \) shares with other faces (interior arcs), \( e(\Pi) \) is the number of arcs it shares with \( \partial D \) (exterior arcs). A \((3, 7)\)-diagram is a diagram where \( e(\Pi) = 0 \) implies \( i(\Pi) \geq 7 \). Note that a \( \Gamma \)-reduced diagram over a \( C'_4(1/6) \)-labelled graph or a \( C'_4(1/6) \)-labelled graph \( \Gamma \) is a \((3, 7)\)-diagram.

The following is a classical fact from small cancellation theory, see e.g. [30, Chapter V].

**Lemma 5.12** (Greendlinger’s lemma). Let \( D \) be a \((3, 7)\)-disk diagram that is not a single face. Then \( D \) contains two faces \( \Pi_1 \) and \( \Pi_2 \) with \( e(\Pi_1) = 1 = e(\Pi_2) \) and \( i(\Pi_1) \leq 3 \) and \( i(\Pi_2) \leq 3 \).

**Lemma 5.13.** Let \( \Gamma_1, \Gamma_2, \ldots, \Gamma_k \) be relators such that \( \Gamma_i \cap \Gamma_{i+1} \neq \emptyset \) (indices mod \( k \)). If \( k = 3 \), then \( \Gamma_1 \cap \Gamma_2 \cap \Gamma_3 \neq \emptyset \). If \( k = 4 \), then \( \Gamma_1 \cap \Gamma_3 \neq \emptyset \) or \( \Gamma_2 \cap \Gamma_4 \neq \emptyset \).

**Proof.** Assume the claim is false for \( 3 \leq k \leq 4 \) and corresponding \( \Gamma_i \). Let \( \gamma = \gamma_1 \gamma_2 \ldots \gamma_k \) be a closed path, where each \( \gamma_i \) is in \( \Gamma_i \). Let \( D \) be a \( \Gamma \)-reduced diagram for \( \gamma \). Choose \( \gamma \) such that, among all possible choices, the number of edges of \( D \) is minimal. Then \( D \) is a disk diagram, and the label of \( \partial D \) is non-trivial in \( F \).

Consider a path \( \pi \) in the intersection of a face \( \Pi \) with some \( \gamma_i \). Then there are lifts \( \pi \to \partial \Pi \to \Gamma_i \) and \( \pi \to \gamma_i \to \Gamma_i \). By our assumption on edge-minimality, these two lifts may never coincide: otherwise, we could replace the copy of \( \pi \) that is a subpath of \( \gamma_i \) by a copy of the complement of \( \pi \) in \( \Pi \). Thus \( \gamma_i \) is a piece (with respect to \( \Gamma \)) and, by minimality, it is locally geodesic. Hence, by the small cancellation condition, \( D \) is not a single face.

Let \( \Pi \) be a face with \( i(\Pi) \leq 3 \) and \( e(\Pi) = 1 \). Then the exterior arc of \( \Pi \) is not a concatenation of at most 3 pieces, since the label of \( \partial D \) is non-trivial in \( F \). Hence, if \( k = 3 \), we have a contradiction. If \( k = 4 \), this arc intersects all the \( \gamma_i \) in edges. This can be true for at most one face \( \Pi \), which contradicts Greendlinger’s lemma.

**Definition 5.14** ([25, Definition 2.11]). A \((3, 7)\)-bigon is a \((3, 7)\)-diagram with a decomposition of \( \partial D \) into two reduced subpaths \( \partial D = \gamma_1 \gamma_2 \) with the following property: Every face \( \Pi \) of \( D \) with
Lemma 5.15 (Strebel's bigons [48, Theorem 35]). Let \( D \) be a \((3,7)\)-bigon. Then any one of its disk components is either a single face, or it has the shape \( I_1 \) depicted in Figure 5.2.1. This means \( D \) has exactly two distinguished faces that have interior degree 1 and exterior degree 1. Moreover, any non-distinguished face has interior degree 2 and exterior degree 2 and intersects both sides of \( D \).

Definition 5.16. We say a sequence of relators \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) is geodesic if \( \Gamma_i \cap \Gamma_{i+1} \neq \emptyset \), and if there exists no sequence of relators \( \Gamma_1 = \Theta_1, \Theta_2, \ldots, \Theta_k = \Gamma_n \) with \( \Theta_i \cap \Theta_{i+1} \neq \emptyset \) and \( k < n \).

Note that since we assume that every generator occurs on \( \Gamma \), we have that for any two relators, there exists a geodesic sequence containing them. Moreover, given vertices \( x, y \in X \) with \( d_X(x, y) = n \), there exists a geodesic sequence of relators \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) with \( x \in \Gamma_1 \) and \( y \in \Gamma_n \) by very definition of \( X \).

Lemma 5.17. If \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) is a geodesic sequence, then \( \Gamma_1 \cup \Gamma_2 \cup \cdots \cup \Gamma_n \) is convex in \( X \).

Proof. Let \( x \) be a vertex in \( \Gamma_i \) and \( y \) a vertex in \( \Gamma_j \). If \( i = j \), then any geodesic from \( x \) to \( y \) stays in \( \Gamma_i \), because \( \Gamma_i \) is convex by [25, Lemma 2.15]. Thus we may assume \( i < j \) and, if \( (given \ x \ and \ y) \) the choices of \( i \) and \( j \) are not unique, choose them such that \( |i - j| \) is minimal. Then there exist non-trivial paths \( \sigma_t \) in \( \Gamma_i \) for \( i \leq t \leq j \) such that \( \sigma := \sigma_i \sigma_{i+1} \cdots \sigma_j \) is a path from \( x \) to \( y \). Let \( \gamma \) be a geodesic in \( X \) from \( x \) to \( y \). Let \( D \) be a \( \Gamma \)-reduced diagram for \( \gamma \sigma^{-1} \) and, given \( x \) and \( y \), among the possible choices for the \( \sigma_t \), choose them such that the number of edges of \( D \) is minimal. Observe that this implies that \( \sigma \) is reduced.

Consider a non-trivial path \( \pi \) in the intersection of a face \( \Pi \) with some \( \sigma_t \). Then, as in the proof of Lemma 5.13, \( \pi \) is a locally geodesic piece and the label of \( \Pi \) is non-trivial in \( F \). Since \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) is a geodesic sequence, \( \Pi \) can intersect at most 3 consecutive \( \sigma_t \). (Recall that the 1-skeleton of any face maps to a subgraph of a relator in \( X \).) Therefore, if \( \Pi \) has \( e(\Pi) = 1 \) and its exterior arc contained in \( \gamma \), then \( i(\Pi) \geq 4 \). The same conclusion holds if \( \Pi \) has \( e(\Pi) = 1 \) and its exterior arc contained in \( \gamma \), because \( \gamma \) is a geodesic in \( X \). Therefore, \( D \) is a \((3,7)\)-bigon.

Let \( \Delta \) be a disk-component of \( D \). If it were a single face \( \Pi \), then, as observed above, \( \Pi \) would intersect \( \sigma \) in at most 3 locally geodesic pieces and the geodesic \( \gamma \) in a path of length at most \( |\partial \Pi|/2 \). This contradicts the fact that any locally geodesic piece has length less than \( |\partial \Pi|/6 \). Therefore, by Lemma 5.15, it has shape \( I_1 \) as shown in Figure 5.2.1. Thus any face \( \Pi \) has interior degree at most 2, whence its intersection with \( \sigma \) has length greater than \( |\partial \Pi|/6 \) – therefore, this intersection

![Figure 1: A diagram \( D \) of shape \( I_1 \). All faces except the two distinguished ones are optional, i.e. \( D \) may have as few as 2 faces.](image)
Lemma 5.17

Now we may replace the subpath $W$. We have that $\eta$ are in (some cyclic shift of) $\pi$. Let $k$ and $\theta$ is not contained in $\Theta$. Suppose it is not. Then there exists some $i$ such that $\gamma$ is contained in a single $\Gamma_i$. Suppose it is not. Then there exists some $i$ such that $\gamma$ is contained in $\Gamma_i$ and $\gamma$ does not contain an edge of $\Gamma_{i+1}$. We have that $T$ is convex, and so are $\Gamma_i$ and $\Gamma_{i+1}$. Therefore, $T \cap \Gamma_i \cap \Gamma_{i+1}$ is convex and hence connected, and there exists an $F$-reduced path $\pi'$ in $T \cap \Gamma_i \cap \Gamma_{i+1}$ with the same endpoints as $\pi$. Now we may replace the subpath $\pi$ of (the cyclic shift of) $\gamma$ by $\pi'$ to obtain a closed path $\gamma'$ with $\omega'(\gamma') < \omega(\gamma)$. Hence, $\gamma'$ is $F$-trivial. We may write a cyclic shift of $\gamma'$ as $\pi' \eta$, where both $\pi'$ and $\eta$ are $F$-reduced. This implies that $\pi'^{-1}$ and $\eta$ are in the same $F$-equivalence class of $F$-reduced paths. Since $\pi'$ is contained in $\Gamma_i \cap \Gamma_{i+1}$, so is $\eta$. We deduce that the original path $\gamma$ was contained in $\Gamma_i \cap \Gamma_{i+1}$, contradicting our assumption.

Let $T_i := \Gamma_i \cap T$. Analogously to above, we define a weight function $\omega'(\theta) = \max\{k : \theta$ is not contained in $\Theta_j \cup \Theta_{i+1} \cup \cdots \cup \Theta_{i+k-1}$ for any $i\}$ and show that a closed path $\theta$ in $T_i$ that is not $F$-trivial and that minimizes $\omega'$ is contained in a single $\Theta_j$. Thus, such a $\theta$ is contained in $\Gamma_i \cap \Theta_j$. But any path in this intersection is a piece, whence $\theta$ cannot exist, and $T$ is an $F$-tree.

Lemma 5.21. Let $n \geq 3$, and let $\Gamma_1, \ldots, \Gamma_n$ and $\Gamma_1, \Theta_2, \Theta_3, \ldots, \Theta_{n-1}, \Gamma_n$ be geodesic sequences such that $\Gamma_i \neq \Theta_j$ for every $2 \leq i, j \leq n - 1$. Then there is an up to $F$-equivalence unique $F$-reduced path in $(\Gamma_2 \cup \Gamma_3 \cup \cdots \cup \Gamma_{n-1}) \cup (\Theta_2 \cup \Theta_3 \cup \cdots \cup \Theta_{n-1})$ that connects a vertex in $\Gamma_1$ to a vertex in $\Gamma_n$ and that does not contain any edge in $\Gamma_1$ or in $\Gamma_n$.

Proof. As both $\Gamma_1 \cup \Gamma_2 \cup \cdots \cup \Gamma_{n-1} \cup \Gamma_n$ and $\Gamma_1 \cup \Theta_2 \cup \cdots \cup \Theta_{n-1} \cup \Gamma_n$ are convex by Lemma 5.17, their intersection is convex and, in particular, connected. Hence, the intersection contains a path $\alpha$ connecting a vertex of $\Gamma_1$ to a vertex of $\Gamma_n$. Observe that the first edge of $\alpha$ outside $\Gamma_1$ must be a piece and not contained in a single $\sigma_i$. This shows that in $\Delta$ there may be at most one face intersecting 3 consecutive $\sigma_i$ in edges – otherwise we would have a path $\sigma_i \sigma_{i+1} \cdots \sigma_{i+k}$ contained in $k$ faces, where $i < t$ and $t + k < j$. This would contradict the fact that $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$ is a geodesic sequence. However, $\Delta$ has two faces with interior degree 1, neither of which can intersect $\sigma_i$ in at most 2 locally geodesic pieces. This is a contradiction to the existence of a disk component, whence $\gamma = \sigma$. \hfill \Box

5.2.2 Parallels in $\hat{X}$

We show that geodesic quadrangles in $\hat{X}$ are uniformly slim in the following sense:

Definition 5.18. We say two geodesic sequences of relators $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$ and $\Theta_1, \Theta_2, \ldots, \Theta_n'$ are parallel if $n = n'$, and $\Gamma_i \cap \Theta_i \neq \emptyset$ for all $i$. We say they are properly parallel if $\Gamma_i \neq \Theta_i$ for all $i$.

Proposition 5.19. Let $\varepsilon > 0$, and let $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$ and $\Theta_1, \Theta_2, \ldots, \Theta_n'$ be geodesic sequences such that $d_X(\Gamma_1, \Theta_1) \leq \varepsilon$ and $d_X(\Gamma_n, \Theta_n') \leq \varepsilon$. Then there exist $k, k', l, l'$ with $\max\{k, k', l, l'\} \leq 9\varepsilon + 3$ and $k + l = k' + l'$ such that $\Gamma_k, \Gamma_{k+1}, \Gamma_{n-l+1}$ and $\Theta_{k'}, \Theta_{k'+1}, \Theta_{n'-l'+1}$ are parallel.

Lemma 5.20. Let $\Gamma_1, \ldots, \Gamma_n$ and $\Theta_1, \ldots, \Theta_n'$ be geodesic sequences such that $\Gamma_i \neq \Theta_j$ for every $i, j$. Then $T := (\Gamma_1 \cup \Gamma_2 \cup \cdots \cup \Gamma_n) \cap (\Theta_1 \cup \Theta_2 \cup \cdots \cup \Theta_n')$ is an $F$-tree.

Proof. Being the intersection of two convex subgraphs (see Lemma 5.17), $T$ is connected. We prove by contradiction: assume there is a closed path in $T$ that is not $F$-trivial. Given a path $\gamma$ in $T$, we define its weight to be $\omega(\gamma) = \max\{k : \gamma$ is not contained in $\Gamma_i \cup \Gamma_{i+1} \cup \cdots \cup \Gamma_{i+k-1}$ for any $i\}$. Let $\gamma$ be a closed path in $T$, not $F$-trivial, such that $\omega(\gamma)$ is minimal among all such paths. We choose $\gamma$ to be cyclically $F$-reduced.

We claim: $\gamma$ is contained in a single $\Gamma_i$. Suppose it is not. Then there exists some $i$ such that (some cyclic shift of) $\gamma$ contains a subpath $\pi$ with: $\eta$, $\tau \pi$ are contained in $\Gamma_i \cap \Gamma_{i+1}$, all edges of $\pi$ are in $\Gamma_{i+1}$ but not in $\Gamma_i$, $\pi$ has at least one edge, and $\gamma$ does not contain an edge of $\Gamma_{i+1}$. We have that $T$ is convex, and so are $\Gamma_i$ and $\Gamma_{i+1}$. Therefore, $T \cap \Gamma_i \cap \Gamma_{i+1}$ is convex and hence connected, and there exists an $F$-reduced path $\pi'$ in $T \cap \Gamma_i \cap \Gamma_{i+1}$ with the same endpoints as $\pi$. Now we may replace the subpath $\pi$ of (the cyclic shift of) $\gamma$ by $\pi'$ to obtain a closed path $\gamma'$ with $\omega(\gamma') < \omega(\gamma)$. Hence, $\gamma'$ is $F$-trivial. We may write a cyclic shift of $\gamma'$ as $\pi' \eta$, where both $\pi'$ and $\eta$ are $F$-reduced. This implies that $\pi'^{-1}$ and $\eta$ are in the same $F$-equivalence class of $F$-reduced paths. Since $\pi'$ is contained in $\Gamma_i \cap \Gamma_{i+1}$, so is $\eta$. We deduce that the original path $\gamma$ was contained in $\Gamma_i \cap \Gamma_{i+1}$, contradicting our assumption.

Let $T_i := \Gamma_i \cap T$. Analogously to above, we define a weight function $\omega'(\theta) = \max\{k : \theta$ is not contained in $\Theta_j \cup \Theta_{i+1} \cup \cdots \cup \Theta_{i+k-1}$ for any $i\}$ and show that a closed path $\theta$ in $T_i$ that is not $F$-trivial and that minimizes $\omega'$ is contained in a single $\Theta_j$. Thus, such a $\theta$ is contained in $\Gamma_i \cap \Theta_j$. But any path in this intersection is a piece, whence $\theta$ cannot exist, and $T$ is an $F$-tree. \hfill \Box
be contained in $\Gamma_2 \cap \Theta_2$ and, likewise, the last edge outside $\Gamma_n$ must be contained in $\Gamma_{n-1} \cap \Theta_{n-1}$. Denote $T := (\Gamma_2 \cup \Gamma_3 \cup \cdots \cup \Gamma_{n-1}) \cap (\Theta_2 \cup \Theta_3 \cup \cdots \cup \Theta_{n-1})$. By Lemmas 5.17 and 5.20, $T$ is a convex $F$-tree, and it intersects both convex graphs $\Gamma_1$ and $\Gamma_n$. Since $T \cap \Gamma_1$ and $T \cap \Gamma_2$ are sub-$F$-trees of $T$, there is an up to $F$-equivalence unique $F$-reduced path in $T$ connecting them as in the claim.

**Lemma 5.22.** Let $\Gamma_1, \Gamma_2, \Gamma_3$ be a geodesic sequence of relators. Up to $F$-equivalence, there exists at most one $F$-reduced path that is a concatenation of at most two pieces in $\Gamma_2$ that intersects $\Gamma_1$ exactly in a vertex and $\Gamma_3$ exactly in a vertex.

**Proof.** Suppose there are $F$-reduced paths $\pi$ and $\hat{\pi}$ as in the statement. Since $\Gamma_i \cap \Gamma_{i+1}$ is connected, there exists an $F$-reduced path $\rho$ in $\Gamma_1 \cap \Gamma_2$ from $i\pi$ to $i\hat{\pi}$; similarly, there exists an $F$-reduced path $\hat{\rho}$ in $\Gamma_2 \cap \Gamma_3$ from $\tau\hat{\pi}$ to $\tau\pi$. By construction, the concatenation $\rho\hat{\rho}\rho^{-1}$ is $F$-reduced. The path $\rho\hat{\rho}\rho^{-1}$ is closed, and it is a concatenation of at most 6 pieces. Therefore, it is $F$-homotopically trivial. Hence the two $F$-reduced paths $\rho\hat{\rho}$ and $\pi$ are $F$-equivalent. Observe that the property of intersecting $\Gamma_1$, respectively $\Gamma_3$, in exactly a vertex is preserved by $F$-equivalence. Thus, $\rho$ and $\hat{\rho}$ must be trivial (i.e. length 0), and $\pi$ and $\hat{\pi}$ are $F$-equivalent.

**Lemma 5.23.** Let $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$ be a geodesic sequence of relators with $n \geq 5$. Then there exists a geodesic path $\pi$ in $X$ contained in $\Gamma_1 \cup \Gamma_2 \cup \cdots \cup \Gamma_{n-2}$ intersecting both $\Gamma_2$ and $\Gamma_{n-1}$ in exactly a vertex each such that: if $\Theta_1, \Theta_2, \ldots, \Theta_n$ is a properly parallel geodesic sequence for $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$, then $\Theta_1 \cup \Theta_2 \cup \cdots \cup \Theta_n$ contains $\pi$.

**Proof.** If there is an $F$-reduced path from $\Gamma_1$ to $\Gamma_3$ in $\Gamma_2$ intersecting $\Gamma_1$ and $\Gamma_3$ only in a vertex, respectively, that is made up of at most 2 pieces, let $x_0$ be the first vertex in it (i.e. the one still in $\Gamma_1$); otherwise let $x_0$ be any vertex in $\Gamma_1 \cap \Gamma_2$. If there is an $F$-reduced path from $\Gamma_{n-2}$ to $\Gamma_n$ in $\Gamma_{n-1}$ made up of 2 pieces, let $y_0$ be the last vertex in it (i.e. the one already in $\Gamma_n$); otherwise let $y_0$ be any vertex in $\Gamma_{n-1} \cap \Gamma_n$. Let $\pi_0$ be a geodesic in $X$ from $x_0$ to $y_0$. By convexity, $\Gamma_2 \cup \Gamma_3 \cup \cdots \cup \Gamma_{n-2}$ contains $\pi_0$. Let $\pi$ be the maximal subpath that intersects $\Gamma_2$ only in a vertex and $\Gamma_{n-1}$ only in a vertex. Let $x$ be its initial vertex and $y$ its terminal vertex.

**Case 1.** Suppose $\Gamma_2$ does not intersect both $\Theta_1$ and $\Theta_3$, and $\Gamma_{n-1}$ does not intersect both $\Theta_{n-2}$ and $\Theta_n$. First, assume $\Gamma_2$ does not intersect $\Theta_1$ but does intersect $\Theta_3$. Then $\Theta_2$ intersects $\Gamma_1$ by Lemma 5.13. Using again Lemma 5.13, we deduce that there exist vertices $v_1$ in $\Gamma_1 \cap \Gamma_2 \cap \Theta_2$, $v_2$ in $\Gamma_2 \cap \Theta_2 \cap \Theta_3$, and $v_3$ in $\Gamma_3 \cap \Gamma_3 \cap \Theta_3$. Hence, there is an $F$-reduced path in $\Gamma_2 \cap \Theta_2$ from $v_1$ to $v_2$ and an $F$-reduced path in $\Gamma_2 \cap \Theta_3$ from $v_2$ to $v_3$, and we may assume that both paths do not contain edges of $\Gamma_1 \cup \Gamma_3$. Note that each of the two paths is a piece. The concatenation of the two paths (after possibly performing a reduction) is an $F$-reduced path as in Lemma 5.22, whence it must contain $x_0$, because $F$-equivalence preserves endpoints. Therefore, $\Theta_1 \cup \Theta_2 \cup \Theta_3$ contains $x_0$.

The case that $\Gamma_2$ does not intersect $\Theta_3$ but does intersect $\Theta_1$ is symmetric. The case that $\Gamma_2$ intersects neither $\Theta_1$ nor $\Theta_3$ produces a path from $\Gamma_1$ to $\Gamma_3$ that lies in $\Gamma_2 \cap \Theta_2$, i.e. that is a single piece, and we again deduce that $\Theta_1 \cup \Theta_2 \cup \Theta_3$ contains $x_0$.

Symmetrically, we also deduce that $\Theta_{n-2} \cup \Theta_{n-1} \cup \Theta_n$ contains $y_0$ and conclude that $\Theta_1 \cup \Theta_2 \cup \cdots \cup \Theta_n$ contains $\pi_0$ by convexity and thus also the subpath $\pi$.

**Case 2.** Suppose $\Gamma_2$ intersects both $\Theta_1$ and $\Theta_3$ or $\Gamma_{n-1}$ intersects both $\Theta_{n-2}$ and $\Theta_n$. First, assume $\Gamma_2$ intersects both $\Theta_1$ and $\Theta_3$. The possibilities are as follows:
Γ_{n-1} intersects Θ_{n-2}. Then Γ_2, Θ_3, Θ_4, ..., Θ_{n-2}, Γ_{n-1} is a geodesic sequence and, hence, contains π_0 by convexity and thus the subpath π. Since π has no edges in Γ_2 ∪ Γ_{n-1}, we deduce that Θ_3 ∪ Θ_4 ∪ ... ∪ Θ_{n-2} contains π.

Γ_{n-1} does not intersect Θ_{n-2}. Then Θ_{n-2} ∪ Θ_{n-1} ∪ Θ_n contains π_0 as discussed in case 1. The sequence Γ_2, Θ_3, Θ_4, ..., Θ_n is geodesic, because it is a connected subsequence of Θ_1, Γ_2, Θ_3, Θ_4, ..., Θ_n, and it contains the endpoints of π_0. Hence, by convexity, it contains π_0 and its subpath π. Since π has no edges in Γ_2, we have that that Θ_3 ∪ Θ_4 ∪ ... ∪ Θ_n contains π.

The case that Γ_{n-1} intersects both Θ_{n-2} and Θ_n is symmetric. □

Corollary 5.24. Let Γ_1, Γ_2, ..., Γ_5 and Θ_1, Θ_2, ..., Θ_5 be geodesic sequences that are both parallel to a geodesic sequence Ξ_1, Ξ_2, ..., Ξ_5. Then (Γ_1 ∪ Γ_2 ∪ ... ∪ Γ_5) ∩ (Θ_1 ∪ Θ_2 ∪ ... ∪ Θ_5) ≠ ∅.

Proof. If both are properly parallel to Ξ_1, Ξ_2, ..., Ξ_5, then Lemma 5.23 implies the claim. If Γ_i = Ξ_i or Θ_i = Ξ_i for some i, the claim is obvious. □

Lemma 5.25. If Γ_1, Γ_2, ..., Γ_{n+k} and Θ_1, Θ_2, ..., Θ_n are geodesic sequences with Γ_1 ∩ Θ_1 ≠ ∅ and Γ_{n+k} ∩ Θ_n ≠ ∅ for k ≥ 0, then k ∈ {0, 1, 2}. Moreover:

0. If k = 0, then Γ_1, ..., Γ_n and Θ_1, ..., Θ_n are parallel, or Γ_2, ..., Γ_n and Θ_1, ..., Θ_{n-1} are parallel, or Γ_1, ..., Γ_{n-1} and Θ_2, ..., Θ_n are parallel. If k = 0, and Θ_1 = Γ_1 or Θ_n = Γ_n, then Γ_1, ..., Γ_n and Θ_1, ..., Θ_n are parallel.

1. If k = 1 then Γ_1, ..., Γ_n and Θ_1, ..., Θ_n are parallel, or Γ_2, ..., Γ_{n+1} and Θ_1, ..., Θ_n are parallel.

2. If k = 2, then Γ_2, ..., Γ_{n+1} and Θ_1, ..., Θ_n are parallel.

Proof. The claim that k ∈ {0, 1, 2} follows immediately from geodesicity. We observe:

A. Let 1 ≤ i < n+k and 1 ≤ j < n, and let x be a vertex in Γ_i ∩ Θ_j and y a vertex in Γ_{n+k} ∩ Θ_n. Let α be a geodesic from x to y in X. If α is contained in Γ_i ∩ Θ_j, then Γ_i ∩ Θ_j ∩ Γ_{n+k} ∩ Θ_n ≠ ∅, and we have i + 1 = n + k and j + 1 = n. Otherwise, by convexity, the first edge of γ outside Γ_i ∩ Θ_j must lie in Γ_{i+1} ∪ Θ_{j+1}. Hence, in both cases we have: Γ_i intersects Θ_{j+1}, or Θ_j intersects Γ_{i+1}.

B. If Γ_i intersects Θ_{i+2} for some i, then for every j ∉ {i, i+1}, Θ_j cannot intersect Γ_{j+1}, because the sequence is geodesic. The symmetric observation holds when exchanging the variables Γ and Θ.

C. Γ_i cannot intersect Θ_{i±k} for k ≥ 3.

Case 0. We prove claim 0, i.e. the case k = 0. We break this up into three subcases.

Case 0.1. Suppose Γ_i intersects Θ_{i+2} for some 1 ≤ i ≤ n − 2. We claim: Γ_j intersects Θ_{j+1} for every i ≤ j ≤ n − 1. Note that if i = n − 2, then Lemma 5.13 yields the claim. Otherwise, we may apply observation A to Γ_i and Θ_{i+2} to deduce: Γ_i intersects Θ_{i+3}, or Γ_{i+1} intersects Θ_{i+2}. Now C forbids the former, whence we have that Γ_{i+1} intersects Θ_{i+2}. 
Now assume we have proven our claim for \( j \) with \( i+1 \leq j \leq n-2 \), and consider \( \Gamma_j \) and \( \Theta_{j+1} \). Observation A shows that \( \Gamma_j \) intersects \( \Theta_{j+2} \), or \( \Gamma_{j+1} \) intersects \( \Theta_{j+1} \). In the first case, we are at the beginning of case 0.1 with the index \( i \) replaced by \( j \) and, hence, are able to show that \( \Gamma_{j+1} \) intersects \( \Theta_{j+2} \). In the second case, we deduce from A that \( \Gamma_{j+2} \) intersects \( \Theta_{j+1} \), or that \( \Gamma_{j+1} \) intersects \( \Theta_{j+2} \). Now, as the former is ruled out by B, the latter holds. Thus, we may use induction to conclude our claim. Observe that proving that \( \Gamma_j \) intersects \( \Theta_{j+1} \) for every \( 1 \leq j \leq i \) is symmetric. Thus, we conclude that \( \Gamma_j \) intersects \( \Theta_{j+1} \) for every \( 1 \leq j \leq n-1 \).

**Case 0.2.** Suppose \( \Theta_i \) intersects \( \Gamma_{i+2} \) for some \( i \). This is symmetric to case 0.1, and \( \Theta_j \) intersects \( \Gamma_{j+1} \) for every \( 1 \leq j \leq n-1 \).

**Case 0.3.** Suppose for no \( i \) we have \( \Gamma_i \) intersects \( \Theta_{i+2} \). Then, by iteratively applying A, we deduce that \( \Gamma_i \) intersects \( \Theta_i \) for every \( 1 \leq i \leq n \). Observe that if \( \Gamma_1 = \Theta_1 \) or if \( \Gamma_n = \Theta_n \), then we must be in this case by geodesicity.

**Case 1.** Let \( k = 1 \). Suppose \( \Gamma_1 \) intersects \( \Theta_2 \) or \( \Theta_{n-1} \) intersects \( \Gamma_{n+1} \). In the first case, \( \Gamma_1, \Theta_2, \Theta_3, \ldots, \Theta_n, \Gamma_{n+1} \) is a geodesic sequence, and claim 0 shows that for each \( 2 \leq i \leq n \), \( \Gamma_i \) and \( \Theta_i \) intersect. In the second case, \( \Gamma_1, \Theta_1, \Theta_2, \ldots, \Theta_{n-1}, \Gamma_{n+1} \) is a geodesic sequence and, again, claim 0 shows that for each \( 2 \leq i \leq n \), \( \Gamma_i \) and \( \Theta_i \) intersect.

Now assume that neither \( \Gamma_1 \) intersects \( \Theta_2 \), nor does \( \Gamma_{n+1} \) intersect \( \Theta_{n-1} \). Then observation A implies that \( \Gamma_2 \) intersects \( \Theta_1 \) and \( \Gamma_n \) intersects \( \Theta_n \). If \( \Gamma_i \) intersects \( \Theta_i \) for all \( 2 \leq i \leq n-1 \), then we are done. If \( \Gamma_1 \) does not intersect \( \Theta_i \) for some \( 2 \leq i \leq n-1 \), then, since \( \Gamma_{n+1} \) does not intersect \( \Theta_{n-1} \), claim 0 shows that \( \Gamma_2, \Gamma_3, \ldots, \Gamma_{n+1} \) and \( \Theta_1, \Theta_2, \ldots, \Theta_n \) are parallel.

**Case 2.** Let \( k = 2 \). Then \( \Gamma_1, \Theta_1, \Theta_2, \ldots, \Theta_n, \Gamma_{n+2} \) is a geodesic sequence. We apply claim 0.

**Corollary 5.26.** Let \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) and \( \Theta_1, \Theta_2, \ldots, \Theta_n' \) be geodesic sequences such that \( \Gamma_1 \cap \Theta_1 \neq \emptyset \) and \( \Gamma_n \cap \Theta_n' \neq \emptyset \). Then \( \Gamma_2, \Gamma_3, \ldots, \Gamma_{n-1} \) is parallel to a connected subsequence of \( \Theta_1, \Theta_2, \ldots, \Theta_n' \), and this subsequence contains \( \Theta_3, \ldots, \Theta_{n'-2} \).

**Lemma 5.27.** Let \( \Gamma_1, \Gamma_2, \ldots, \Gamma_n \) and \( \Theta_1, \Theta_2, \ldots, \Theta_n' \) be geodesic sequences and \( \Xi \) and \( \Xi' \) be relators with such that both \( \Gamma_1 \) and \( \Theta_1 \) intersect \( \Xi \) and both \( \Gamma_n \) and \( \Theta_n' \) intersect \( \Xi' \). Then \( \Gamma_9, \Gamma_{10}, \ldots, \Gamma_{n-8} \) is parallel to a connected subsequence of \( \Theta_7, \Theta_8, \ldots, \Theta_{n'-6} \).

**Proof.** Choose a geodesic sequence \( \Xi = \Xi_1, \Xi_2, \ldots, \Xi_{n'} = \Xi' \). Corollary 5.26 implies that both \( \Gamma_2, \Gamma_3, \ldots, \Gamma_{n-1} \) and \( \Theta_2, \Theta_3, \ldots, \Theta_{n'-1} \) are parallel to connected subsequences of \( \Xi_1, \Xi_2, \ldots, \Xi_{n'} \) that both contain \( \Xi_3, \Xi_4, \ldots, \Xi_{n'-2} \). Hence both \( \Gamma_2, \Gamma_3, \ldots, \Gamma_8 \) and \( \Theta_2, \Theta_3, \ldots, \Theta_8 \) contain parallel sequences for \( \Xi_3, \Xi_4, \Xi_5, \Xi_6, \Xi_7 \). Thus we may invoke Corollary 5.24 to deduce that there exist \( 1 \leq i, j \leq 8 \) such that \( \Gamma_i \) and \( \Theta_j \) intersect. Similarly, we obtain \( 0 \leq i', j' \leq 7 \) such that \( \Gamma_{n-i'} \) and \( \Theta_{n'-j'} \) intersect. Now Corollary 5.26 implies that \( \Gamma_9, \Gamma_{10}, \ldots, \Gamma_{n-8} \) is parallel to a connected subsequence of \( \Theta_1, \Theta_2, \ldots, \Theta_{n'} \).

Since \( \Gamma_9 \) cannot intersect \( \Theta_k \) for \( k \leq 6 \) and \( \Gamma_{n-8} \) cannot intersect \( \Theta_{n-k} \) for \( k \leq 5 \), our claim follows.

**Proof of Proposition 5.19.** By assumption, there exist \( k, k' \leq \varepsilon \) and geodesic sequences \( \Xi_1, \Xi_2, \ldots, \Xi_k \) and \( \Xi_1, \Xi_2, \ldots, \Xi_{k'} \) such that \( \Xi_i \) intersects \( \Gamma_i \), \( \Xi_1 \) intersects \( \Theta_1 \), \( \Xi_i \) intersects \( \Gamma_n \) and \( \Xi_{k'} \) intersects \( \Theta_{n'} \). Let \( K := \max\{k, k'\} \). Now for each \( 1 \leq i \leq K \), choose a geodesic sequence \( \Xi_i \) from \( \Xi_{\min\{i, k\}} \) to \( \Xi_{\min\{i, k'\}} \). Denote by \( \Xi_{K+1} \) the sequence \( \Theta_1, \Theta_2, \ldots, \Theta_{n'} \).

We claim: for each \( 2 \leq i \leq K+1 \), \( \Gamma_{i+8(i-1)}, \ldots, \Gamma_{n-8(i-1)} \) is parallel to a connected subsequence of \( \Xi_i \) that does not contain the endpoints of \( \Xi_i \). We argue by induction. For \( i = 2 \), the claim
follows from Lemma 5.27. Now suppose we have shown our claim for some \(2 \leq k \leq K + 1\). Then \(\xi_k\) is a parallel to a connected subsequence of \(\Xi_{k+1}\) by Lemma 5.25. Therefore, Lemma 5.27 implies that \(\Gamma_{1+8k}, \ldots, \Gamma_{n-8k}\) is parallel to a connected subsequence of \(\Xi_{k+1}\), and the claim is proved.

Thus \(\Gamma_{1+8\varepsilon}, \ldots, \Gamma_{n-8\varepsilon}\) is parallel to a connected subsequence of \(\Theta_1, \ldots, \Theta_{n'}\). Now since \(d_X(\Gamma_1, \Theta_j) \leq \varepsilon\), we have that \(\Gamma_{1+8\varepsilon}\) cannot intersect \(\Theta_j\) with \(j > 9\varepsilon + 3\), and a similar observation holds of \(\Gamma_{n-8\varepsilon}\) and \(j < n' - 9\varepsilon - 2\), whence our result follows.

5.2.3 The action on parallels in \(\bar{X}\)

We show that, given two geodesic sequences \(\gamma\) and \(\theta\) of relators, there are only boundedly many elements in \(g \in G(\Gamma)\) such that \(\gamma\) and \(g\theta\) are parallel.

**Proposition 5.28.** Let \(\Gamma\) be a \(C'(1/6, p)\)-labelled graph, or a \(C'_6(1/6, p)\)-labelled graph. Let \(\Gamma_1, \Gamma_2, \ldots, \Gamma_n\) and \(\Theta_1, \Theta_2, \ldots, \Theta_n\) be parallel geodesic sequences with \(n \geq 21\). Then there exist at most \(8p + 100\) elements \(g \in G(\Gamma)\) such that \(\Gamma_1, \Gamma_2, \ldots, \Gamma_n\) and \(g\Theta_1, g\Theta_2, \ldots, g\Theta_n\) are parallel.

We first explain how this yields Theorem 5.10.

**Proof of Theorem 5.10 using Proposition 5.28.** Let \(\varepsilon > 0\) and let \(x \in G\) with \(d_X(1, x) = n \geq 18\varepsilon + 25\). Let \(g \in G(\Gamma)\) with \(d(1, g) \leq \varepsilon\) and \(d(x, gx) \leq \varepsilon\). Let \(\Gamma_1, \ldots, \Gamma_n\) be a geodesic sequence of relators from 1 to \(x\). Then \(d_X(\Gamma_1, g\Gamma_1) \leq \varepsilon\) and \(d_X(\Gamma_n, g\Gamma_n) \leq \varepsilon\). Hence, there exist \(0 \leq k, k', l, l' \leq 9\varepsilon + 3\) for which the statement of Proposition 5.19 holds. Observe that since \(k + l = k' + l'\), the choice of \(k, l, k', l'\) determines \(l'\). We obtain parallel sequences of length at least \(n - k - l + 2 \geq n - 2(9\varepsilon + 3) + 2 \geq 21\). Thus, we are in the case of Proposition 5.28 and, given \(l, l', k, k'\), there are at most \(8p + 100\) possibilities for \(g\). Therefore, there are at most \((9\varepsilon + 4)^3(8p + 100)\) possibilities for \(g\) in total.

We will now prove Proposition 5.28. In the following, we still assume that \(\Gamma\) satisfies the \(C'(1/6)\)-condition or the \(C'_6(1/6)\)-condition.

**Lemma 5.29.** Let \(\Gamma_1, \ldots, \Gamma_n\) be a geodesic sequence, and let \(g\) with \(g\Gamma_1 = \Gamma_1\) and \(g\Gamma_n = \Gamma_n\). Then we have \(g\Gamma_i = \Gamma_i\) for all \(1 \leq i \leq n\).

**Proof.** We prove by contradiction and, hence, may assume \(n \geq 3\) and \(g\Gamma_i \neq \Gamma_i\) for all \(2 \leq i \leq n - 1\). Note that being geodesic implies \(g\Gamma_j \neq \Gamma_i\) for every \(i \neq j\). Let \(\alpha\) be a geodesic in \(X\), starting in \(\Gamma_1\) and ending in \(\Gamma_n\). Since \(\alpha\) starts in \(\Gamma_1 = g\Gamma_1\) and ends in \(\Gamma_n = g\Gamma_n\), both \(\Gamma_1 \cup \Gamma_2 \cup \cdots \cup \Gamma_n\) and \(g\Gamma_1 \cup g\Gamma_2 \cup \cdots \cup g\Gamma_n\) contain \(\alpha\) by convexity. Let \(\alpha'\) be the subpath of \(\alpha\) from the last vertex in \(\Gamma_1\) to the first vertex in \(\Gamma_n\). Then \(\alpha'\) is a path from \(\Gamma_1 \cap g\Gamma_1\) to \(\Gamma_n \cap g\Gamma_n\) in \((\Gamma_1 \cup \cdots \cup \Gamma_n) \cap (g\Gamma_1 \cup \cdots \cup g\Gamma_n)\) as in the statement of Lemma 5.21.

Consider the path \(g\alpha'\). The same arguments as above, together with the facts \(\Gamma_1 = g\Gamma_1\) and \(\Gamma_n = g\Gamma_n\), show that \(g\alpha'\) is a path from \(\Gamma_1 \cap g\Gamma_1\) to \(\Gamma_n \cap g\Gamma_n\) in \((\Gamma_1 \cup \cdots \cup \Gamma_n) \cap (g\Gamma_1 \cup \cdots \cup g\Gamma_n)\) as in the statement of Lemma 5.21. Hence, by the uniqueness statement of Lemma 5.21, we have \(g\alpha' = \alpha'\) by Lemma 5.21. Therefore, \(g = 1\). This is a contradiction to \(g\Gamma_2 \neq \Gamma_2\).

The following lemma is a variation on [25, Lemma 4.11].

**Lemma 5.30.** Let \(\Gamma\) be a \(C'(1/6)\)-labelled graph or a cylinder-free \(C'_6(1/6)\)-labelled graph. Let \(\Gamma_0, \Gamma_1, \Gamma_2\) be a geodesic sequence of relators. If \(g \in G(\Gamma)\) satisfies \(g\Gamma_i = \Gamma_i\) for all \(i\), then \(g = 1\).
Proof. Let $\gamma_1$ be a path in $\Gamma_1$ intersecting both $\Gamma_0$ and $\Gamma_2$ such that $|\gamma_1| = d_X(\Gamma_0, \Gamma_2)$. The set of $g \in G(\Gamma)$ with $g\Gamma_i = \Gamma_i$ is in bijection with the set of triples $(\varphi_0, \varphi_1, \varphi_2)$ of label-preserving automorphisms of the $\Gamma_i$ such that $\varphi_0(\gamma_1) = \varphi_1(\gamma_1)$ and $\varphi_2(\tau\gamma_1) = \varphi_1(\tau\gamma_1)$. We show $\varphi_1$ is the identity.

Suppose $\varphi_1$ is not the identity. Then there exist locally geodesic paths $\pi$ from $\nu \gamma_1$ to $\varphi_1(\nu \gamma_1)$ in $\Gamma_0 \cap \Gamma_1$ and $\rho$ from $\tau \gamma_1$ to $\varphi_1(\tau \gamma_1)$ in $\Gamma_1 \cap \Gamma_2$. Note that both $\pi$ and $\rho$ are pieces and, more strongly, for any $k$, the paths $\pi_k := \pi \varphi_1(\pi) \varphi_1^2(\pi) \ldots \varphi_1^k(\pi)$ and $\rho_k := \rho \varphi_1(\rho) \varphi_1^2(\rho) \ldots \varphi_1^k(\rho)$ are pieces. Moreover, so are locally geodesic paths with the same endpoints and labelled by the same elements of $F$ as $\pi_k$, respectively $\rho_k$; we denote these by $\hat{\pi}_k$ and $\hat{\rho}_k$.

We first consider the free case: if $\varphi_1$ is not the identity, then $\ell(\rho_k) = \ell(\rho)^k$ in $F$, whence $\ell(\pi)^k$ is freely non-trivial. Also observe that no subpath of $\hat{\pi}_k$ or of $\hat{\rho}_k$ can be closed, as otherwise we would have a simple closed path that is a piece. In particular, $\varphi_1$ must have infinite order. By construction, for any $k$, the path $\theta_k := \gamma_1 \hat{\rho}_k \varphi_1^k(\gamma_1) \hat{\pi}_k^{-1}$ is a simple closed path. Since $|\hat{\pi}_k| \to \infty$ and $|\hat{\rho}_k| \to \infty$ as $k \to \infty$ and $\hat{\pi}_k$ and $\hat{\rho}_k$ are pieces, this path eventually violates the $C'(1/6)$-condition.

In the free product case, if $\pi$ or $\rho$ are not contained in a single attached Cayley graph, then, again $|\hat{\pi}_k| \to \infty$ or $|\hat{\rho}_k| \to \infty$ as $k \to \infty$, and, again, the $C'_6(1/6)$-condition is violated eventually. Hence, we may assume that $\pi$ is contained in an attached component $1$ and $\rho$ is contained in an attached component $2$. Observe that, since $\varphi((\pi)) = \pi\pi$, we have $\varphi(C_1) \cap C_2 \neq \emptyset$, whence $\varphi$ leaves $C_1$ invariant. The same observation holds for $C_2$. Since $\Gamma_0$ and $\Gamma_2$ are disjoint, so are $C_1$ and $C_2$. Thus, cylinder-freeness implies the claim.

Lemma 5.31. Assume that $\Gamma$ satisfies the $C'(1/6, p)$-condition or the $C'_6(1/6, p)$ condition, and let $\varepsilon > 0$. Let $\gamma$ and $\theta$ be geodesics in $X$, and let with $d_X(\nu \gamma, \tau \gamma) > 1$ and $d_X(\nu \theta, \tau \theta) > 1$. Then there exist at most $\lceil \varepsilon p \rceil$ elements $g \in G(\Gamma)$ such that $g \theta$ is an $F$-subpath of $\gamma$ with $d_X(g \gamma, g \theta) \leq \varepsilon$.

Proof in the free group case. Let $r$ be a shortest word in the generators such that there exist $w$ a proper initial subword of $r$ and $N$ a positive integer with: $r^N w$ is word and $r^N w = \ell(\theta)$. Being shortest, $r$ is not a proper power of a word. We thus have: if $x$ is a word such that $xr$ is an initial subword of $r^N w$, then there exists some $k$ with $x = r^k$.

For simplicity of notation, assume that $\theta$ is a subpath of $\gamma$ as required in the assumption, i.e. $g = 1$ satisfies the claim, and, moreover, $d_X(\nu \gamma, \theta)$ is minimal among all possible $G(\Gamma)$-translates of $\theta$ which are subpaths of $\gamma$. (This is no restriction, up to replacing $\theta$ by a translate.) Let $g \in G(\Gamma)$ be non-trivial satisfying the assumptions, and let $x$ be the label of the subpath of $\gamma$ from $\nu \theta$ to $g \theta$. Then $xr$ is an initial subword of $r^N w$. Thus $x = r^k$ for some $k$ by the above observation. It remains to restrict $k$.

By [25, Proposition 3.6], a path in $X$ labelled by geodesic word $y$ can be covered by at most $|y|_X$ relators. Since $d_X(1, r^N w) > 1$, we have that not all powers of $r$ appear on $\Gamma$. Hence, by the $p$-condition, at most the $p - 1$st power occurs, and the same holds true for any cyclic conjugate of $r$. Hence, $\varepsilon \geq |r^k|_X > k/p$, whence $1 \leq k < \varepsilon p$. Thus, including the case $g = 1$, we get at most $\lceil \varepsilon p \rceil$ elements.

We now give (local) terminology for the free product case: if $w$ is a word in the generators, then a subword $u$ is a syllable if it is a maximal subword whose letters come from a single generating factor. A word $w$ is reduced if all its syllables represent non-trivial elements of their respective generating factors. A concatenation of non-empty reduced words $w_1 w_2 \ldots w_k$ is strongly reduced if the terminal syllable of $w_1$ is in a different generating factor than the initial syllable of $w_{i+1}$. An initial $F$-subword $u$ of $w$ is defined as follows: if $u$ is a word with $k$ syllables, then the first $k - 1$
coincide with the first $k - 1$ syllables of $w$, and the $k$-th syllable lives in the same generating factor as the $k$-th syllable of $w$; $u$ is a proper initial $F$-subword if it has fewer syllables than $w$.

**Proof in the free product case.** Let $r$ be a shortest word in the generators such that there exist $w$ a proper initial $F$-subword of $r$ and $N$ a positive integer with: $r^N w$ is strongly reduced and $r^N w = \ell(\theta)$ in $F$. Observe that, since $\delta(\theta \tau \theta) > 1$, $\ell(\theta)$ is not contained in a single generating factor and, therefore, neither is $r$. Hence, being shortest, $r$ does not represent a proper power of an element of $F$. We thus have: if $x$ is a word such that $x r$ is strongly reduced and equal in $F$ to an initial subword of $r^N w$, then there exists some $k$ with $x = r^k$ in $F$.

We repeat the proof as before: for simplicity of notation, assume that $\theta$ is an $F$-subpath of $\gamma$ as required in the assumption, i.e. $g = 1$ satisfies the claim, and, moreover, $(\gamma(\nu \gamma, \theta))$ is minimal among all possible $G(\Gamma)$-translates of $\theta$ which are $F$-subpaths of $\gamma$. (This is no restriction, up to replacing $\theta$ by a translate.) Let $g \in G(\Gamma)$ be non-trivial satisfying the assumptions, and let $x$ be the label of the subpath of $\gamma$ from $\theta$ to $g \theta$. Then $x r$ is strongly reduced by definition of an $F$-subpath, and it is equal in $F$ to an initial subword of $r^N w$. Thus $x = r^k$ in $F$ for some $k$ by the above observation. It remains to restrict $k$.

By [25, Proposition 3.6], a path in $X$ labelled by geodesic word $y$ can be covered by at most $|y|_X$ relators. Also observe: given two $F$-equivalent paths, both are covered by the same collection of relators. We conclude as in the free group case. □

**Proof of Proposition 5.28.** Let $N = 10$. First, let $g \in G(\Gamma)$ such that $\Gamma_1, \Gamma_2, \ldots, \Gamma_N = \Theta_1, \Theta_2, \ldots, \Theta_N$ are properly parallel. Let $\gamma$ be the geodesic path in $\Gamma_3 \cup \Gamma_4 \cup \ldots \cup \Gamma_{N-2}$ from $\Gamma_2$ to $\Gamma_{N-1}$ that is contained in every properly parallel sequence for $\Gamma_2, \Gamma_3, \ldots, \Gamma_{N-1}$ obtained in Lemma 5.23. In particular, $\gamma$ contains no edges of $\Gamma_2$ or $\Gamma_{N-1}$. Let $\theta$ be a geodesic path in $\Theta_5 \cup \Theta_6 \cup \ldots \cup \Theta_{N-4}$ from $\Theta_4$ to $\Theta_{N-3}$ that is contained in every sequence properly parallel to $\Theta_4, \ldots, \Theta_{N-3}$ from Lemma 5.23. Note that $\gamma$ and $\theta$ are defined independently of $g$.

Let $T := (\Gamma_1 \cup \Gamma_2 \cup \ldots \cup \Gamma_N) \cap (g \Theta_1 \cup g \Theta_2 \cup \ldots \cup g \Theta_3)$, which, by Lemma 5.20, is an $F$-tree. Let $\pi_0$ be the up to $F$-equivalence unique path in $T$ from $\Gamma_1 \cap g \Theta_1$ to $\Gamma_N \cap g \Theta_N$ that does not contain edges of $\Gamma_1 \cap \Theta_1$ or of $\Gamma_N \cap \Theta_N$. Such a path exists by construction and is unique (up to $F$-equivalence) because we are considering connected subsets of an $F$-tree. Let $\pi$ be the $F$-subpath of $\pi_0$ that intersects $\Gamma_2$ and $\Gamma_{N-1}$ in exactly a vertex each. Since $\gamma$ is contained in $T$ and it is an $F$-reduced path that intersects $\Gamma_2$ and $\Gamma_{N-1}$ in exactly a vertex each, we conclude that, up to $F$-equivalence, $\pi$ and $\gamma$ coincide.

Observe that $\Gamma_2 \cap g \Theta_5 = \emptyset$ and $g \Theta_{N-4} \cap \Gamma_{N-1} = \emptyset$, as we are considering geodesic sequences. Therefore, the initial vertex of $\gamma$ is contained in $g \Theta_1 \cup g \Theta_2 \cup g \Theta_3 \cup g \Theta_4$ and, likewise, its terminal vertex is contained in $g \Theta_{N-3} \cup g \Theta_{N-2} \cup g \Theta_{N-1} \cup g \Theta_N$. Therefore, $\gamma$ contains an $F$-subpath in $g \Theta_5 \cup g \Theta_6 \cup \ldots \cup g \Theta_{N-4}$ intersecting both $g \Theta_4$ and $g \Theta_{N-3}$ in exactly a vertex. As above, we conclude that, up to $F$-equivalence, this $F$-subpath coincides with $g \theta$. In other words: $g \theta$ is an $F$-subpath of $\gamma$. We have $d(\gamma, \tau \gamma) \geq (N - 1) - 2 - 1 > 1$ and $d(\gamma, \tau \theta) \geq (N - 3) - 4 - 1 > 1$. Moreover, $d(\gamma, \gamma, g \theta) \leq 4$. Thus, we may apply Lemma 5.31 with $\varepsilon = 4$ to conclude: there exist at most $4p$ elements $g \in G(\Gamma)$ such that the initial subsegments of length $N$ of $\Gamma_1, \Gamma_2, \ldots, \Gamma_n$ and $g \Theta_1, g \Theta_2, \ldots, g \Theta_n$ are properly parallel.

For the case that the terminal subsegments of length $N$ are properly parallel, the same observation holds, bringing our count of elements $g$ to at most $8p$.

Finally, consider the case that both the initial subsegment and the terminal subsegment of length $N$ are not properly parallel. This means there exist $1 \leq i \leq N$ and $N - 1 \leq j \leq n$ with $\Gamma_i = g \Theta_1$ and $\Theta_j = g \Gamma_j$. If we have another $g'$ with $\Gamma_i = g' \Theta_1$ and $\Theta_j = g' \Gamma_j$ then Lemma 5.29
shows that \( g^t \Theta_i = g \Theta_i \) for every \( i \leq t \leq j \). In particular, this holds for \( N \leq t \leq N + 2 \), because \( N + 2 \leq n - N + 1 \). Therefore, given \( i \) and \( j \), there exists at most 1 such \( g \) by Lemma 5.30. This gives a grand total of at most \( 8p + N^2 \) elements.

5.3 Characterization of elliptic elements

In this section, we give a complete characterization of the elliptic elements for the action of \( G(\Gamma) \) on \( \tilde{X} \). In particular, we show that every element is either elliptic or hyperbolic. As a corollary, we obtain a generalization of the Torsion Theorem for small cancellation groups to graphical small cancellation theory, even over free products, thus generalizing the corresponding classical results [18, 32], see also [21, 35, 22, 47] for results on the torsion-freeness of certain graphical small cancellation groups.

**Proposition 5.32.** Let \( \Gamma \) be a \( C'(1/6) \)-labelled graph or a \( C'_\ast(1/6) \)-labelled graph, and let \( g \in G(\Gamma) \). Then the following are equivalent:

1. \( g \) is elliptic for the action on \( \tilde{X} \);
2. \( g \) is not hyperbolic for the action on \( \tilde{X} \);
3. \( g \) is conjugate to an element of \( G(\Gamma) \) represented by a word all whose powers occur on \( \Gamma \).

**Proof.** Let \( g \in G(\Gamma) \), and let \( w \) be a word in \( S \) minimizing the lengths of words representing elements of the set \( \{ h \in G(\Gamma) : \exists n \in N : h^n \sim g \} \subseteq G(\Gamma) \), where \( \sim \) denotes conjugacy in \( G(\Gamma) \). We consider the following two cases studied by Gruber in [23, Section 4]:

1. every power of \( w \) occurs on \( \Gamma \), or
2. there exists some \( C_0 > 0 \) such that the longest subword of a power of \( w \) occurring on \( \Gamma \) has length at most \( C_0 \).

In case (1), the element \( h \) represented by \( w \) is elliptic, whence so is \( g \). It remains to show that in case (2), \( h \) is hyperbolic, which will imply hyperbolicity of \( g \).

It is shown in [23, Section 4] that, for every \( n \), there exist a geodesic word \( g_n \) representing \( w^n \) and a \( \Gamma \)-reduced diagram \( B_n \) with boundary word \( w^n g_n^{-1} \) such that

1. every disk component of \( B_n \) is a single face or has shape \( I_1 \) as in Figure 5.2.1, its two sides being subpaths of the sides of \( B_n \) corresponding to \( w^n \) (denoted \( \omega_n \)) and corresponding to \( g_n^{-1} \) (denoted \( \gamma_n \)),
2. every face \( \Pi \) of \( B_n \) has \( |\partial \Pi| < 6C_0 \),
3. the intersection of every face \( \Pi \) with \( \omega_n \) has length less than \( (2/3)|\partial \Pi| \).
4. if \( \Pi \) and \( \Pi' \) are consecutive faces in a disk component, then \( |\Pi \cap \gamma_n| > |\partial \Pi|/6 \) or \( |\Pi' \cap \gamma_n| > |\partial \Pi'|/6 \). (Here, consecutive means: sharing interior edges.)

The first 3 bullets are stated explicitly in [23], and the last bullet is deduced as follows: if both \( \Pi \) and \( \Pi' \) do not satisfy the claim, then \( |\Pi \cap \omega_n| > |\Pi|/2 \) and \( |\Pi' \cap \omega_n| > |\partial \Pi'|/2 \) by the small cancellation hypothesis. Therefore, both \( |\partial \Pi| \geq 2|w| \) and \( |\partial \Pi'| \geq 2|w| \) by the minimality hypothesis on \( w \). Hence, [23, Lemma 4.10] shows that both \( \Pi \) and \( \Pi' \) are special in the sense of [23, Lemma 4.11],
whence we may apply [23, Lemma 4.11] as follows: if $a$ is the arc in the intersection of $\Pi$ and $\Pi'\,'$, then $|\Pi \cap \omega_n| + |a| < |w| + |\partial \Pi'|/6 \leq 2|\partial \Pi|/3$. Apart from $a$, $\Pi$ has at most one additional interior arc, and this arc must have length less than $|\partial \Pi|/6$. Therefore, $|\Pi \cap \gamma_n| > |\partial \Pi|/6$, a contradiction.

Let $\sigma$ be a covering segment, i.e. a copy of a path in $\Gamma$ that is a subpath of $\gamma_n$. If $\sigma$ completely contains $\partial \Pi \cap \gamma_n$ for a face $\Pi$ with $|\partial \Pi \cap \gamma_n| > |\partial \Pi|/6$, then $\sigma \cup \Pi^{(1)}$ lifts to $\Gamma$, because $\sigma \cap \Pi$ is not a piece. We show that $\sigma$ cannot contain $(\Pi_1 \cup \Pi_2) \cap \gamma_n$ for 2 consecutive faces $\Pi_1$ and $\Pi_2$ in a disk component: for a contradiction, assume $\sigma$ does contain it. Suppose that $|\Pi_1 \cap \sigma| > |\partial \Pi_1|/6$. (Here we use the fourth bullet; the case where this holds for $\Pi_2$ follows by symmetry.) Then $\sigma \cup \Pi_1^{(1)}$ lifts to $\Gamma$, because $\sigma \cap \Pi_1$ is not a piece. Since $B_n$ is $\Gamma$-reduced, two consecutive faces in a disk component cannot lift together to $\Gamma$. Hence, $(\Pi_1 \cap \Pi_2) \cup (\Pi_2 \cap \sigma)$ is a piece (considering this embedded line graph as path). Thus, $\partial \Pi_2$ is a concatenation of at most 2 pieces and $\Pi_2 \cap \omega_n$. But this implies $|\Pi_2 \cap \omega_n| > (2/3)|\partial \Pi_2|$, a contradiction to the third bullet. Hence, $\sigma$ cannot contain the intersection of $\gamma_n$ with a disk component of $B_n$ of shape $I_1$, and, moreover, the parts of $\sigma$ contained in disk components of shape $I_1$ have total length less than $4(6C_0)/2 = 12C_0$ (using the second bullet).

If $\sigma$ contains $\Pi \cap \gamma_n$, where $\Pi$ is its own disk component, then, $\sigma \cup \Pi^{(1)}$ lifts to $\Gamma$, and we can replace $\sigma$ by a path $\tilde{\sigma}$ containing $\Pi \cap \omega_n$ instead of $\Pi \cap \gamma_n$, and $\tilde{\sigma}$ is also a copy of a path in $\Gamma$. Since $g_n$ is a geodesic word, we have $|\tilde{\sigma}| \geq |\sigma|$. We conclude that the parts of $\sigma$ contained in disk components consisting of single faces together with the parts of $\sigma$ not contained in any faces at all have total length at most $C_0$.

We conclude $|\sigma| < 13C_0$. Since every disk component of $B_n$ has shape $I_1$, we have $|g_n| \geq n|w|/C_0$. Hence, by [25, Proposition 3.6], we obtain $d_X(1, h^n) > n(|w|/C_0)/(13C_0)$, whence $h$ and, therefore, $g$ is hyperbolic.

**Corollary 5.33 (Torsion theorem).** Let $\Gamma$ be a $C'(1/6)$-labelled graph or $C'_*$$(1/6)$-labelled graph, and let $g \in G(\Gamma)$ be of order $n \in \mathbb{N} \setminus \{1\}$. Then there exist a connected component $\Gamma_0$ of $\Gamma$ and a label-preserving automorphism $\varphi$ of $\Gamma_0$ of order $n$ such that $g$ is conjugate to the element of $G(\Gamma)$ represented by the label of a path $v \to \varphi(v)$ for a vertex $v$ in $\Gamma_0$, or (only in the free product case) $g$ is conjugate to an order $n$ element of a generating factor.

**Proof.** Since $g$ has finite order, it must act elliptically on $X$. Therefore, by Proposition 5.32, a conjugate of $g$ is represented by a word $w$ such that every power of $w$ occurs on $\Gamma$. Now since every component of $\Gamma$ embeds into $\text{Cay}(G(\Gamma), S)$, non-triviality and finite order of $g$ imply that some proper power of $w$ must occur on a closed path $\gamma$ in a component $\Gamma_0$ of $\Gamma$, say starting from some vertex $v$, labelled by $w^k$ for some $k > 1$. We choose $k$ minimal with this property. Then $g$ has order $k$.

If (in the free product case) $w$ is contained in a single generating factor, then the second claim holds, because each generating factor embeds in $G(\Gamma)$. Otherwise, $\gamma$ is not $F$-homotopically trivial, and the small cancellation condition implies that $\gamma$ cannot be a piece. Thus, there exists an automorphism $\varphi$ of $\Gamma_0$ such that $\varphi(v)$ lies on $\gamma$ and the initial subpath $\pi$ of $\gamma$ from $v$ to $\varphi(v)$ is labelled by $w$. Since the path $\pi \varphi(\pi) \varphi^2(\pi) \ldots \varphi^{k-1}(\pi)$ is labelled by $w^k$ and, therefore, is closed, we obtain that $\varphi$ has order $k$. This argument also applies in the free group case.

### 5.4 Description of maximal elementary subgroups

We show that the elementary closure of every hyperbolic element is infinite cyclic or infinite dihedral. In particular, if there is no even torsion, it must be infinite cyclic.
Proposition 5.34. Let $\Gamma$ be a $C'(1/6)$-labelled graph or a cylinder-free $C'_1(1/6)$-labelled graph. Let $g$ be a hyperbolic element for the action of $G(\Gamma)$ on $\hat{X}$, and let $h$ be an elliptic element such that $g$ and $h$ commute. Then $h = 1$.

Proof. Proposition 5.32 tells us that there exists $t \in G(\Gamma)$ such that $th^{-1}$ of $h$ is represented by a (possibly empty) cyclically reduced word all whose powers appear on $\Gamma$. We have that $th^{-1}$ and $tg^{-1}$ commute if and only if $g$ and $h$ do, $h$ is elliptic if and only if $th^{-1}$ is, and $g$ is hyperbolic if and only if $tg^{-1}$ is. Hence, without loss of generality, we assume that $h$ itself is represented by a cyclically reduced word $w$ such that all powers of $w$ appear on $\Gamma$.

First, assume there exists a path $\pi$ in a component $\Gamma_0$ of $\Gamma$ such that $\pi$ is labelled by $w$, and such that there exists an automorphism of $\Gamma_0$ that takes $\iota \pi$ to $\tau \pi$. This implies: if $\Gamma_1$ is the relator in $X$ that is the image of $\Gamma_0$ under the map induced by $i \pi \mapsto 1 \in G(\Gamma)$, then $h\Gamma_1 = \Gamma_1$. Now choose $k$ such that $d_X(1, g^k) \geq 3$. In particular, this ensures $\Gamma_1 \cap g\Gamma_1 = \emptyset$. Choose a geodesic sequence $\Gamma_1, \Gamma_2, \ldots, \Gamma_l = g\Gamma_1$. Then $h\Gamma_1 = \Gamma_1$ and $h\Gamma_l = hg\Gamma_1 = gh\Gamma_1 = g\Gamma_1 = \Gamma_l$. Therefore, Lemmas 5.29 and 5.30 prove the claim.

Now assume that there does not exist such an automorphism as above. This implies: any path labelled by a power of $w$ is a piece in $\Gamma$. Now, in the free group case, denote by $\Theta$ a bi-infinite line graph labelled by the powers of $w$. In the free product case, denote by $\Theta$ the completion (see Definition 5.3) of a bi-infinite line-graph labelled by the powers of $w$. Consider the graph $\hat{\Gamma} := \Gamma \sqcup \Theta$. Then $\hat{\Gamma}$ defines the same group as $\Gamma$, the same Cayley graph $X$ and the same coned-off space $\hat{X}$. We claim that $\hat{\Gamma}$ satisfies the same small cancellation condition as $\Gamma$: all powers of $w$ label pieces in $\hat{\Gamma}$. Hence, in the free group case, adding $\Theta$ does not introduce new pieces. In the free product case, observe that whenever a path $p$ in $\Gamma$ is a piece, then so is every path in the completion of the support of $p$. Therefore, again, adding $\Theta$ does not introduce new pieces. As all closed paths in $\Theta$ are $F$-trivial, there are also no new simple closed paths to consider when checking the small cancellation condition.

Now the connected component $\Theta$ of $\hat{\Gamma}$ admits a path $\pi$ labelled by $w$ and an automorphism taking $i\pi$ to $\tau\pi$. Hence, we may apply our above argument for $\hat{\Gamma}$ instead of $\Gamma$. $\square$

Corollary 5.35. Let $H$ be a virtually cyclic subgroup of $G(\Gamma)$ that contains a hyperbolic element. Then $H$ is either infinite cyclic or infinite dihedral. In particular, if $G(\Gamma)$ has no even torsion, then $H$ is infinite cyclic.

Proof. As $H$ is virtually infinite cyclic, we may write $H = K \rtimes C$, where $C$ is either infinite cyclic or infinite dihedral and contains a hyperbolic element $g$. Both $C_1 := \langle g \rangle$ and the kernel $C_2$ of the action by conjugation of $C$ on $K$ have finite indices in $C$. Thus, $C_1 \cap C_2$ is non-trivial and contains a hyperbolic element commuting with every element of $K$, whence $K$ is trivial. $\square$

5.5 The case that $G(\Gamma)$ acts elementarily

The following proposition will handle the degenerate case of Theorem 2.4.

Proposition 5.36. Let $p \in \mathbb{N}$, $n$ odd, and $\Gamma$ be a $C'_n(1/6, p)$-labelled graph whose set of labels $S$ has at least two elements. Then either $G(\Gamma)$ acts non-elementarily on $X$, or $G(\Gamma) \in \mathfrak{B}_n$. If $G(\Gamma)$ is finite, then $\Gamma$ contains $\text{Cay}(G(\Gamma), S)$.

Notice that $p$ does not appear in the proof. The actual (weaker) version of (iii) of Definition 2.3 we require is: whenever, for a cyclically reduced word $w$, all powers of $w$ label paths in $\Gamma$, then $w^n$ labels a closed path in $\Gamma$. 
Proof. We shall assume that any two connected components of $\Gamma$ are non-isomorphic. Suppose $G := G(\Gamma)$ contains a hyperbolic element. Then, since the action is acylindrical by Theorem 5.10, $G$ is either virtually cyclic or acts non-elementarily on $X$.

If $G$ is virtually cyclic then Corollary 5.35 implies that $G$ is infinite cyclic and, in particular, abelian. Consider two different elements $s_1$ and $s_2$ of $S$ and a $\Gamma$-reduced diagram $D$ for the word $s_1s_2s_1^{-1}s_2^{-1}$. Since $\Gamma$ contains neither loops nor bigons, $D$ has no cut-points. If $D$ has at least two faces, then we may apply Greendlinger’s lemma to deduce that $D$ has at least two faces $\Pi_1$ and $\Pi_2$ of interior degree at most 3 each. In particular, we have for each $i = 1, 2$ that $|\partial \Pi_i \cap \partial D| > |\partial \Pi_i \setminus \partial D| \geq 3$, whence $|\partial D| \geq 8$, a contradiction.

Thus, $D$ consists of a single face with boundary length 4. This implies that neither $s_1$ nor $s_2$ can label pieces. Hence, there exist automorphisms $\varphi_1$ and $\varphi_2$ of $\Gamma$ and edges $e_i$ with $\ell(e_i) = s_i$ and $\varphi(e_i) = \tau e_i$. Hence the $C'_n(1/6, p)$-condition implies that the elements of $G(\Gamma)$ represented by $s_i$ have orders dividing $n$. Since $s_1$ and $s_2$ were arbitrary, $G(\Gamma)$ is a quotient of $\bigoplus_{s \in S} \mathbb{Z}/n\mathbb{Z}$, which contradicts the existence of an infinite order element.

Thus we may assume that $G(\Gamma)$ contains no hyperbolic element. Note that since $S$ is non-empty, this implies that $\Gamma$ is non-empty.

Assume $\Gamma$ has no component with non-trivial fundamental group. Then $G(\Gamma)$ is a non-trivial free group. As every element is elliptic, Proposition 5.32 implies that there exist arbitrarily high powers of freely non-trivial words read on paths in $\Gamma$ and, as every component has trivial fundamental group, these paths must be simple and, in particular, not closed. This contradicts the $C'_n(1/6, p)$-condition. On the other hand, assume $\Gamma$ has more than one component with non-trivial fundamental group. Then it follows from [25] that $G(\Gamma)$ does contain a hyperbolic element for the action on $X$, contradicting our assumption. Therefore, we from now on assume that $\Gamma$ has exactly one component $\Gamma_0$ with non-trivial fundamental group.

Let $g \in G(\Gamma)$ be a non-trivial element. Since $g$ is not hyperbolic, Proposition 5.32 implies that $g$ is elliptic and conjugate to an element of $G(\Gamma)$ that is represented by a word $w$ read on $\Gamma$ such that every power of $w$ can be read on $\Gamma$. By assumption, we have that $w^n$ is read on a closed path in $\Gamma_0$, and say this loop is based at a vertex $v$. The $C'(1/6)$-condition implies that a path labelled by $w^n$ cannot be a piece, whence there exists an automorphism $\varphi$ of $\Gamma_0$ such that $w$ is the label of a path from $v$ to $\varphi(v)$. Note that this implies that $\varphi$ has order dividing $n$.

The label-preserving map $\Gamma_0 \to X$ that takes $v$ to 1 induces a homomorphism $\text{Aut}(\Gamma_0) \to G(\Gamma)$, sending $\psi$ to the element represented by a path from $v$ to $\psi(v)$. Denote by $H$ the image of this homomorphism. Then our above considerations show: $G(\Gamma) = \bigcup_{g \in G(\Gamma)} ghg^{-1}$. Moreover, every element of $H$, and therefore every element of $G(\Gamma)$, has order dividing $n$, whence we have $G(\Gamma) \subseteq B_n$.

Suppose $G(\Gamma)$ is finite. It is an easy exercise in group theory to show that whenever a group $G_1$ is the union the of conjugates of a finite index subgroup $G_2$, then $G_1 = G_2$. Hence, if $G(\Gamma)$ is finite, then $G(\Gamma) = H$, which implies that $\Gamma$ is actually the (finite) Cayley graph of $G(\Gamma)$ with respect to $S$. \hfill \Box

6 Proofs of the main results

We now give a proof of Theorems 2.4 and 2.8. These statements actually follow from a more general result. Indeed as explained at the beginning of Section 5 we are working with a graph $\Gamma$ satisfying weaker hypotheses – namely the $C'_c(\lambda, p)$ and $C'_{\lambda}^2(\lambda, p)$ conditions – which allows the graph $G(\Gamma)$ to have infinite order elliptic elements for its action on the corresponding coned-off Cayley graph.
As usual our result has two variants, one for the usual graphical small cancellation and one for graphical small cancellation over free products. While their proofs are exactly the same, we found it clearer to state them separately.

**Theorem 6.1.** Let \( p \in \mathbb{N}^* \) and \( r \in \mathbb{R}_+ \). There exists \( n_{p,r} \in \mathbb{N} \) such that for every odd exponent \( n \geq n_{p,r} \) the following holds. Let \( \Gamma \) be a graph labelled by a set \( S \) satisfying the \( C'(1/6,p) \)-condition. Assume that \( G = G(\Gamma) \) has no even torsion. We focus on the action of \( G \) of the cone-off space \( \hat{X} = \hat{X}(\Gamma) \). There exists a quotient \( Q \) of \( G \) with the following properties.

(i) Every elliptic subgroup of \( G \) embeds in \( Q \).

(ii) For every \( g \in Q \) that is not the image of an elliptic element we have \( g^n = 1 \).

(iii) If every elliptic subgroup of \( G \) belongs \( \mathcal{B}_n \) then \( Q \) is isomorphic to \( G/G_n \). In particular \( Q \) is isomorphic to \( G_n(\Gamma) \) and belongs to \( \mathcal{B}_n \).

(iv) If the action of \( G \) on \( \hat{X} \) is non elementary then \( Q \) is infinite. Moreover the projection \( G \to Q \) is one-to-one on small balls in the following sense. For every \( g \in G \setminus \{1\} \), for every \( x \in \hat{X} \), if \( |g x - x|_{\hat{X}} \leq r \), then the image of \( g \) in \( Q \) is not trivial. In particular, if \( r \geq 1 \), then every connected component of \( \Gamma \) embeds in the Cayley graph of \( Q \) with respect to \( S \).

**Theorem 6.2.** Let \( p \in \mathbb{N}^* \) and \( r \in \mathbb{R}_+ \). There exists \( n_{p,r} \in \mathbb{N} \) such that for every odd exponent \( n \geq n_{p,r} \) the following holds. Let \( (F_i)_{i \in I} \) be a collection of groups. For each \( i \in I \) we fix a generating set \( S_i \) of \( F_i \) and let \( S = \sqcup_{i \in I} S_i \). Let \( \Gamma \) be a graph labelled by \( S \) satisfying the \( C'_n(1/6,p) \)-condition. Assume that \( G = G(\Gamma) \) has no even torsion. We focus on the action of \( G \) of the cone-off space \( \hat{X} = \hat{X}(\Gamma) \). There exists a quotient \( Q \) of \( G \) with the following properties.

(i) Every elliptic subgroup of \( G \) embeds in \( Q \). In particular, every \( F_i \) embeds in \( Q \).

(ii) For every \( g \in Q \) that is not the image of an elliptic element we have \( g^n = 1 \).

(iii) If every elliptic subgroup of \( G \) belongs \( \mathcal{B}_n \) then \( Q \) is isomorphic to \( G/G_n \). In particular \( Q \) is isomorphic to \( G_n(\Gamma) \) and belongs to \( \mathcal{B}_n \).

(iv) If the action of \( G \) on \( \hat{X} \) is non elementary then \( Q \) is infinite. Moreover the projection \( G \to Q \) is one-to-one on small balls in the following sense. For every \( g \in G \setminus \{1\} \), for every \( x \in \hat{X} \), if \( |g x - x|_{\hat{X}} \leq r \), then the image of \( g \) in \( Q \) is not trivial. In particular, if \( r \geq 1 \), then every connected component of \( \Gamma \) embeds in the Cayley graph of \( Q \) with respect to \( S \).

**Proof of Theorems 6.1 and 6.2.** Let \( p \in \mathbb{N}^* \) and \( r \in \mathbb{R}_+ \). We define a hyperbolicity constant \( \delta = 80 \). Let \( \Gamma \) be a labelled graph satisfying the conditions of Theorem 6.1 or Theorem 6.2. We write \( G = G(\Gamma) \) for the corresponding group and \( \hat{X} = \hat{X}(\Gamma) \) for its coned-off Cayley graph. According to Theorem 5.9 the cone-off space \( \hat{X} \) is \( \delta \)-hyperbolic. Moreover by Theorem 5.10, there exist constants \( L \) and \( N \), only depending on \( p \), such that the action of \( G \) on \( \hat{X} \) is \((100\delta, L, N)\)-hyperbolic. We assumed that \( G \) has no even torsion. Hence if the action of \( G \) is elementary, then \( G \) is either elliptic or isomorphic to \( \mathbb{Z} \) (Corollary 5.35). In such a situation the first three conclusions of both theorems are obvious. Hence from now on we assume that the action of \( G \) on \( \hat{X} \) is non-elementary.

Since \( G \) has no even torsion, every lineal subgroup of \( G \) is torsion free (Corollary 5.35). It follows that the \( e(G, \hat{X}) = 1 \) (see Definition 3.6 for the definition of this parameter). Consequently we can
apply Proposition 4.1. We denote by $n_{p,r}$ the critical exponent $N_i$ given by Proposition 4.1 applied with the parameters $N$, $L$, $\delta$ and $r$. Observe that $n_{p,r}$ only depends on the chosen $p$ and $r$, not on the specific $\Gamma$. Fix an odd exponent $n \geq n_{p,r}$. The first three conclusions of Theorems 6.1 and 6.2 follow from Proposition 4.1. Recall indeed that in the context of small cancellation over free products, the graph $\Gamma$ is its own completion (see Definition 5.2), whence every factor $F_i$ we started with acts elliptically on $X$. The first half of Point (iv) in both theorems is also a consequence of Proposition 4.1. The second half follows from this observation: the vertex set of each embedded component of $\Gamma$ in $\text{Cay}(G,S)$ has diameter at most 1 in the metric of $X$.

We are ready to prove our main result.

Proof of Theorem 2.4. Let $p \in \mathbb{N}^*$. Let $n_p$ the critical exponent of Theorem 6.1 for $p$ and $r = 2$, i.e. $n_p := n_{p,2}$. Let $\Gamma$ be a graph labelled by a set $S$ containing at least two elements and satisfying the $C'_n(1/6,p)$ condition. We assume that there is no finite groups $F$ generated by $S$ such that $\Gamma$ contained the Cayley graph of $F$ with respect to $S$. It follows from Proposition 5.36 that either $G(\Gamma)$ is already an infinite group in $\mathfrak{H}_n$ or the action of $G(\Gamma)$ on the cone-off Cayley graph $\tilde{X}(\Gamma)$ is non-elementary. In the first case $G_n(\Gamma) = G(\Gamma)$ and the conclusion follows from the usual graphical small cancellation theory [35, Theorem 1] or [22, Lemma 4.1 and Theorem 4.3].

Let us focus on the second case, that is when the action of $G(\Gamma)$ on $\tilde{X}(\Gamma)$ is non elementary. We denote by $Q$ the quotient given by Theorem 6.1. Proposition 5.32 tells us that every elliptic element for the action of $G(\Gamma)$ on $\tilde{X}$ has order dividing $n$. Thus the group $G_n(\Gamma)$ coincides with $Q$, which is infinite. Moreover, every component of $\Gamma$ embeds in $\text{Cay}(G_n(\Gamma), S)$.

It remains to prove Point (iii). In this claim, $S$ is finite, every component of $\Gamma$ is finite, and $\Gamma$ is countable. Since $G_n(\Gamma)$ is infinite and every component of $\Gamma$ embeds in $\text{Cay}(G_n(\Gamma), S)$, we observe that $\Gamma$ embeds in $\text{Cay}(G_n(\Gamma), S)$. It remains to prove the coarse embedding result. We follow the strategy of Gruber [22, Theorem 4.3] to obtain our result. For simplicity we let $G_n = G_n(\Gamma)$, $X = \text{Cay}(G,S)$, and $X_n = \text{Cay}(G_n,S)$.

If $\Gamma$ is finite, any map $\Gamma \to X_n$ satisfies the axioms of a coarse embedding, hence there is nothing to prove. Therefore we can assume that $\Gamma$ is infinite. By lining up the (finite) components of $\Gamma$ on a 1-infinite geodesic ray in $X_n$, we can choose a label-preserving graph homomorphism $f : \Gamma \to X_n$ such that $d(\Gamma_i, \Gamma_j) \geq \text{diam}(\Gamma_i) + \text{diam}(\Gamma_j) + i + j$. We show that $f$ is a coarse embedding.

Consider (by abuse of notation) $\Gamma_i$, $i$ and $\Gamma_j$, two images in $X_n$ of connected components of $\Gamma$ under any label-preserving graph homomorphism. We claim that $\Gamma_i \cap \Gamma_j$ is empty or connected. Let $x$ and $y$ be vertices in $\Gamma_i \cap \Gamma_j$. Let $\tilde{x}$ be a preimage of $x$ via the map $X \to X_n$. According to [22, Lemma 4.1] $\Gamma_i$ also embeds in $X$. Let us denote by $\tilde{\Gamma}_i$ a copy of $\Gamma_i$ in $X$. Recall that every map we are considering is label-preserving. Hence up to replacing $\tilde{\Gamma}_i$ by a translate of $\tilde{\Gamma}_i$, we may always assume that $\tilde{x}$ belongs to $\Gamma_i$ and that the map $X \to X_n$ maps $\tilde{\Gamma}_i$ onto $\Gamma_i$. We build in the same way a lift $\tilde{\Gamma}_j$ of $\Gamma_j$ containing $\tilde{x}$. Let $\tilde{y}_i$ be the resulting preimage of $y$ in $\Gamma_i$ and $\tilde{y}_j$ the one in $\tilde{\Gamma}_j$, and observe $|\tilde{y}_i - \tilde{y}_j|_X \leq 2$. Denote by $g$ the element of $G(\Gamma)$ with $g\tilde{y}_i = \tilde{y}_j$. Since both $\tilde{y}_i$ and $\tilde{y}_j$ map to $y$, the image of $g$ in $G_n$ is trivial. Hence, by Theorem 6.1 (iv), $g$ is trivial in $G(\Gamma)$, and $\tilde{y}_i = \tilde{y}_j$. Now by [25, Lemma 2.17], $\tilde{\Gamma}_i \cap \tilde{\Gamma}_j$ is connected. Hence, there is a path $\gamma$ in this intersection connecting $\tilde{x}$ to $\tilde{y}_j$. The image of $\gamma$ in $X_n$ lies in $\Gamma_i \cap \Gamma_j$ and connects $x$ to $y$, whence $\Gamma_i \cap \Gamma_j$ is connected.
We now prove coarse embedding by contradiction: let \((x_k, y_k) \subset \Gamma \times \Gamma\) be a sequence of pairs of vertices such that \(|x_k - y_k|_1 \to \infty\) and \(|f(x_k) - f(y_k)|_{X_*}\) is bounded. Since \(d(f(\Gamma_i), f(\Gamma_j)) \geq \text{diam}(\Gamma_i) + \text{diam}(\Gamma_j) + i + j\) we may, by possibly going to a subsequence, assume that for each \(k\) there exists \(j_k\) such that \(x_k, y_k \in \Gamma_{j_k}\). Again going to a subsequence and using local finiteness of \(X_n\), we may assume that there exists a fixed \(g \in G_n\) such that \(f(x_k)^{-1}f(y_k) = g\) for every \(k\). Now \(f(x_1)^{-1}\Gamma_{j_1} \cap f(x_k)^{-1}\Gamma_{j_k}\) contains \(g\) and, as shown above, is connected for each \(k\). Thus, \(f(x_1)^{-1}\Gamma_{j_1} \cap f(x_k)^{-1}\Gamma_{j_k}\) contains a simple path from 1 to \(g\), and the length of such a simple path is bounded by \(|V\Gamma_{j_1}| - 1\). Hence \(|V\Gamma_{j_i}| - 1 \geq |x_k - y_k|_{\Gamma_{j_k}}\), which contradicts \(|x_k - y_k|_{\Gamma_{j_k}} \to \infty\).

We are also ready to prove our main theorem in the (classical) free product case. Recall from Section 5.1 that a presentation satisfying the (classical) power-free \(C'_p(1/6, p)\)-condition for which the generating factors do not have even torsion can be regarded as satisfying the (graphical) \(C'_p(1/6, p)\)-condition. The graphical version of our result will be stated immediately after.

**Proof of Theorem 2.8.** Let \(G\) be a small cancellation quotient of a free product \(F = F_1 \ast \cdots \ast F_m\) and \(X\) be the corresponding cone-off space. Note that every factor \(F_k\) acts elliptically on \(X\) (recall that when constructing \(X\), we consider the graph \(\Gamma\) that is the completion of a disjoint union of cycle graphs labelled by the generators). Moreover the power-free \(C'_p(\lambda, p)\)-condition together with Proposition 5.32 implies that an element \(g \in G\) is elliptic if and only if it is conjugate to an element of one of the \(F_k\). The result is now a direct application of Theorem 6.2.

**Theorem 6.3.** Let \(p \in \mathbb{N}^*\). There exists a critical exponent \(n_p \in \mathbb{N}\) such that for every odd integer \(n \geq n_p\) the following holds. Let \((F_i)_{i \in I}\) be a collection of groups. For each \(i \in I\) we fix a generating set \(S_i\) of \(F_i\) and let \(S = \sqcup_{i \in I} S_i\). Let \(\Gamma\) be a graph labelled by \(S\) satisfying the \(C'_p(1/6, p)\)-condition such that the action of \(G(\Gamma)\) on its cone-off space \(X\) is non-elementary. Additionally assume that whenever \(w\) is a cyclically reduced word all whose powers label paths in \(\Gamma\), then \(w^n\) labels a closed path in \(\Gamma\). Denote \(G_n(\Gamma) := G(\Gamma)/G(\Gamma)^n\). Then the following holds.

(i) The group \(G_n(\Gamma)\) is infinite.

(ii) Every connected component of \(\Gamma\) embeds into \(\text{Cay}(G_n(\Gamma), S)\) via a label-preserving graph homomorphism.

(iii) Each one of the generating factors \(F_i\) embeds as a subgroup in \(G_n(\Gamma)\).

**Remark 6.4.** Observe that our assumptions imply that every \(F_i\) is \(n\)-periodic.

**Proof.** Proposition 5.32 and the assumptions imply that every elliptic element for the action of \(G(\Gamma)\) on \(X\) has order dividing \(n\). The proof now goes as the first part of the one in the non-elementary case of Theorem 2.4 using Theorem 6.2 instead of Theorem 6.1.

We conclude by providing an example that shows that our restriction on proper powers appearing as subwords of relators is indeed necessary in order to obtain infinite \(n\)-periodic groups.

**Example 6.5** (Pride group [41]). Let \(S = \{a, b\}\). We consider relations of the form

\[
\begin{align*}
  r_n &= a^{-1}bp^nab^nbp^n \ldots b_p^n b^n \\
  s_n &= b^{-1}aq^nba^nq^n a^n q^n \ldots a^n q^n
\end{align*}
\]

and take the group \(G = \langle a, b \mid r_n, s_n, n \in \mathbb{N} \rangle\). Under a suitable choice of \((p_i)\) and \((q_j)\) this presentation satisfies the \(C'_p(1/6, 3)\) assumption. Observe though that \(G/G^n\) is trivial for every \(n\). On the
other hand, $a$ acts elliptically on the cone-off space $\hat{X}(\Gamma)$, whence particular the infinite cyclic group $\langle a \rangle$ embeds in $Q$, and $Q$ is not a torsion group. This does not contradict Theorem 2.4, because our presentation does not satisfy $C'_n(1/6,3)$-condition for any $n$.

Clearly, if one prescribes $n$, already the group given by the 2-generator and 2-relator presentation $\langle a, b \mid r_n, s_n \rangle$ does not admit any non-trivial $n$-periodic quotient. Notice that we may achieve any small cancellation parameter we desire, i.e. make the presentation of Pride’s group satisfy any given $C'(\lambda)$-condition. Consequently, we can achieve any positive upper bound for the relative lengths of subwords that are proper powers. This shows that an absolute upper bound on the powers occurring as subwords of relators is indeed required for making any statement in the nature of our main results.
