Key words: middle-altitude, non-small cell lung cancer, cancer tissues, micro ribonucleic acid

Abstract. Micro ribonucleic acid (miRNA) expression profile in non-small cell lung cancer (NSCLC) tissues in middle-altitude area was analyzed using the Affymetrix chip technique, to predict the target genes of abnormally-expressed miRNAs, and to analyze the target gene-related signaling pathways and cell biological functions regulated by them. The difference in miRNA expression profile in NSCLC tissues was analyzed using the Affymetrix chip technique. Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) was performed for the verification of some differentially-expressed miRNAs. The genes predicted by at least 6 out of 12 commonly used prediction methods of miRNA target genes, based on miRWalk2.0, were considered as target genes. The functions of differentially-expressed miRNA target genes were analyzed via Gene Ontology (GO) enrichment analysis, and the main signaling pathways involving target genes were analyzed via Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis. There was abnormal expression of miRNAs in NSCLC tissues in the middle-altitude area. There were 140,405 target genes predicted for differentially-expressed miRNAs. The GO enrichment analysis of the functions of the target genes of differentially expressed miRNAs revealed that they mainly influence the binding process of intracellular components to protein, the positive regulation of biological process and the regulation of metabolic process. Moreover, these target genes were mainly enriched in the immunity, gene expression, metabolism and signal transduction, among which signal transduction was enriched with the most genes. The expression levels of miRNA-139-5p and miRNA-150-5p in lung cancer group were lower than those in the control group. The expression of miRNAs in NSCLC tissues in the middle-altitude area is abnormal, and most miRNAs are downregulated.

Introduction

There are numerous diagnostic methods for lung cancer, such as sputum pathology, tumor markers, imaging, CT scan, percutaneous lung puncture, and fiberoptic bronchoscopic and surgical tissue biopsy. Sputum cytologic culture is a traditional diagnostic method with high diagnostic specificity of >98%, but the sensitivity is only 66% (1). A trend toward lower sensitivity was noted for lesions that were <2 cm in diameter. However, sensitivity is higher for central lesions than for peripheral lesions. Therefore, for lesions <2 cm in diameter, CT is better than sputum cytology, especially in peripheral lung cancer. Although its diagnostic sensitivity is improved by cytologic smears, the arrangement mode of cancer cells is often changed during the smear process, harming the pathological diagnosis of lung cancer. There is a number of studies on the abnormal expression of micro ribonucleic acid (miRNA) in lung cancer tissues. However, the results are inconsistent or the biological functions remain unclear (1-3). The abnormal expression of miRNA is also related to environment and genetics, which also have prognostic risks (4). Whether the expression of miRNAs is inconsistent in lung cancer tissues and serum is unknown, and it has been reported that the miR-133 expression is increased in both lung cancer tissues and serum (5). According to the MeDIP-chip microarray analysis, there is methylation of miRNAs (miR-10b, miR-1179, miR-137, miR-572, miR-3150b and miR-129-2) in primary lung tumor, and miR-1179 mimics prevent cell growth through inhibiting the target gene CCNE1 (6).

miRNA is a kind of non-coding small-molecule RNA, which can target a variety of genes. miRNA is involved in regulating various biological processes, including the cell signal expression, proliferation, differentiation and apoptosis. Each miRNA can regulate hundreds of messenger RNAs (mRNAs) in a parallel and targeted manner, and any change in its expression level may produce significant influences on biological processes and lead to pathophysiological changes (7). Tumor cells are in a special hypoxic microenvironment, and hypoxia will occur once the tumor diameter becomes more than several
The clinical stage of the above NSCLC patients was T1-2N0M0 of adenocarcinoma, according to pathological classification. There were 17 cases of squamous cell carcinoma and 13 cases of lung puncture, and were confirmed by immunohistochemistry. Patients were obtained by surgical resection or percutaneous biopsy of lung tissues (Fig. 1), and had no malignant tumors in other organs. Further 34 non-tumor patients, admitted to the Qinghai Provincial People’s Hospital during the same period and living in a middle-altitude area (altitude: 1,500 - 2,500 m), they were selected as the control group, which included 24 males and 10 females with an average age of 64.58±12.56 years and age range of 41-77 years. The cancer tissues of all lung cancer patients of this study and/or their guardians were informed and signed an informed consent form. All study processes met the ethical requirements and were reviewed and approved by the Ethics Committee of the Qinghai Provincial People’s Hospital (approval no. 2015-07).

**Patients and methods**

*Study subjects.* A total of 30 patients admitted to the Respiratory and Critical Disease Department and Oncology Department of the Qinghai Provincial People’s Hospital (Xining, China) from October 2016 to October 2017, who were definitely diagnosed with NSCLC via pathological biopsy of lung tissues (Fig. 1), were selected as the lung cancer group. There were 22 males and 8 females enrolled, with an average age of 64.58±12.56 years and age range of 41-77 years. The cancer tissues of all lung cancer patients were obtained by surgical resection or percutaneous biopsy of lung tissues, and were confirmed by immunohistochemistry. There were 17 cases of squamous cell carcinoma and 13 cases of adenocarcinoma, according to pathological classification. The clinical stage of the above NSCLC patients was $T_{2-3}N_0M_0$ for all the patients according to the WHO classification (11). The patients of the lung cancer group lived permanently in a middle-altitude area (altitude: 1,500-2,500 m), they were diagnosed initially with primary tumor and did not receive any treatment (chemoradiotherapy, molecular targeted therapy, or surgical resection), and had no malignant tumors in other organs. Further 34 non-tumor patients, admitted to the Qinghai Provincial People’s Hospital during the same period and living permanently in a middle-altitude area, were selected as the control group, which included 24 males and 10 females with an average age of 59.36±14.08 years and age range of 39-75 years. Samples were collected from marginal normal lung tissue obtained from non-tumor patients with pneumothorax by surgical resection. There were no significant differences in sex ($\chi^2=0.0594$, P=0.8074) and age (t=1.556, P=0.1247) between the two groups (P=0.05), and thus, they were comparable. The patients of this study and/or their guardians were informed and signed an informed consent form. All study processes met the ethical requirements and were reviewed and approved by the Ethics Committee of the Qinghai Provincial People’s Hospital.

**miRNA extraction, miRNA reverse transcription and miRNA polymerase chain reaction (PCR).** Total RNA was extracted from cells using the TRIzol reagent (Ambion; Thermo Fisher Scientific, Inc.). miRNA reverse transcription was performed using the TaqMan® MicroRNA Reverse Transcription kit (Applied Biosystems Life Technologies; Thermo Fisher Scientific, Inc.), and PCR primers corresponding to miRNAs were synthesized by Applied Biosystems (Thermo Fisher Scientific, Inc.). miRNA-16 was used as an internal reference. Sequences of miR-139-5p and miR-150-5p primers were: miRNA-139-5p forward, GTCGTATCCGTCAGGGTCCAGGTATGGACCAA and reverse, TCTACAGTGAGAAGGGCTGCAGGGATACGACA; miRNA-150-5p forward, GTCGTATCCGTCAGGGTCCAGGGTACGACA and reverse, GCTTCGAGACCGAACTAC; miRNA-16 forward, GTCGTATCCGTCAGGGTCCAGGGTACGACA and reverse, AGACACGCGGCAAATGCTGA; miRNA-1 U6 forward, GTCGTATCCGTCAGGGTCCAGGGTACGACA and reverse, AAGCCTTCCAGATTGGCGC. PCR was performed with QuantStudio™ 7 Flex Real-Time PCR system (Thermo Fisher Scientific, Inc.) by using the 2-ΔΔCt method (12). Reaction system (15 µl): 7 µl Master Mix I (0.15 µl of 100 mM dNTPs with dTTP, 1.00 µl of 50 U/µl MultiScribe™ Reverse Transcriptase, 1.5 µl 10X Reverse Transcriptase Buffer, 0.19 µl of 20 U/µl RNase Inhibitor, and 4.16 µl nuclease-free water), 3 µl 5X RT primer and 5 µl RNA sample. Master Mix (MultiScribe™ Reverse Transcriptionase, Reverse Transcriptase Buffer, RNase Inhibitor, nuclease-free water) was derived from TaqMan® MicroRNA Reverse Transcription kit. The reverse transcription conditions were: 16°C for 30 min, 42°C for 30 min and 85°C for 5 min. RT-qPCR amplification system (20 µl): 1.00 µl TaqMan Small Assay (20X; Applied Biosystems Life Technologies; Thermo Fisher Scientific, Inc.), 1.33 µl product from RT reaction, 10 µl TaqMan Universal PCR master mix II (2X; Applied Biosystems Life Technologies; Thermo Fisher Scientific, Inc.) and 7.67 µl nuclease-free water. Amplification conditions were as follows: Option AmpErase UNG activity at 50°C for 2 min, enzyme activation at 95°C for 10 min, a total of 40 cycles, denaturation at 95°C for 15 sec, and annealing/extension at 60°C for 60 sec.

**Immunohistochemistry.** EnVision system (Dako; Agilent Technologies, Inc.) was used to detect the expression of TTF-1 (MAB-0599), Napsin A (MAB-0704), CK7 (MAB-0166), P40 (MAB-0666), CK5/6 (MAB-0276), and P63 (MAB-0365) proteins. All protein antibodies were purchased from Fuzhou Maixin Biotechnology Development Co., Ltd. Tissues were fixed in 4% neutral buffered formaldehyde for 24 h at room temperature. The experimental procedure was as follows: Paraffin-embedded tissues were cut into 3-4 µm and heated overnight at 65°C. The tissue sections were deparaffinized and rehydrated. Inactivation of endogenous peroxidase (3% H2O2, 10 min) and washing with PBS for 3 times, every 2 min, were carried out. The antigen hot fix was EDTA, pH 9.0, 20 min. The tissues were washed with PBS 3 times, every 2 min in distilled water prior to being blocked at room temperature.
for 10 min (goat serum working solution; Beijing Zhongshan Golden Bridge Biotechnology Co., Ltd.). Incubation with the primary antibody was carried out for 1 h at room temperature (with TTF-1 1:50, NapsinA 1:50, CK7 1:100, P40 1:50, CK5/6 1:100, P63 1:50) and then the tissues were washed with PBS 3 times, every 2 min. Secondary antibody was added using MaxVision™ HRP-Polymer anti-Mouse/Rabbit IHC kit (cat no. 5010; Fuzhou Maixin Biotechnology Development Co., Ltd.) at room temperature for 25 min. Washing with PBS for 3 times, every 2 min followed. DAB chromogenic reagent was used to detect the protein expression for 3-10 min (ready-to-use DAB color liquid, microscopic control). The slides were subsequently stained with hematoxylin and bluing was carried out. Sliced tissues were conducted with graded alcohol dehydration and xylene following the manufacturer’s instructions. Leica DM2500 optical microscope (Leica Microsystems, Ltd.) was used for observation. H&E staining in serial sections of each paraffin block specimens was performed for immunohistochemistry and expression analysis (Fig. 1).

**GeneChip scanning of lung cancer tissues.** Four patients diagnosed with NSCLC via pathological biopsy (E8, E2-t, E6-t and E9; Fig. 2A), and 5 non-tumor patients (C6, C8, C5, C1 and C3; Fig. 2A) were selected. The cancer and non-tumor tissues were collected and stored at -80˚C for Affymetrix GeneChip® scanning (Affymetrix: Thermo Fisher Scientific, Inc.). Selection criteria for the lung cancer patients: i) Long-term residence in the middle-altitude area; ii) initial diagnosis of patients who did not receive any treatment (chemotherapy, molecular targeted therapy, or surgical resection); iii) patients with primary tumor; and iv) no other organ malignancy. Selection criteria for control patients: i) Patients with pneumothorax; and ii) no lung or other organ tumors. miRNAs were selected to expand the sample for verification, according to the following conditions: i) miRNAs consistently expressed according to the results of microarray and the published literature; ii) miRNAs with downregulated expression; and iii) miRNAs reported to be associated with lung cancer. miR-139-5p and miR-150-5p with obvious differential expression were verified by RT-qPCR with expanded sample size.

**Statistical analysis**

**Chip difference analysis.** The chip image information was converted into digital signal using the Affymetrix® GeneChip® Console® software (Affymetrix: Thermo Fisher Scientific, Inc.). The probe signal was integrated into the probeset signal, and the inter-sample variation caused by non-biological factors was removed via inter-chip normalization. The data were preprocessed using Range Migration Algorithm (RMA) (13). Differential genes were analyzed by Significance Analysis of Microarrays (SAM) R software package (https://www.r-project.org/), and the significant difference of chip data was analyzed. Differential genes were screened based on P<0.05 and fold change >2 or <0.5.

**Cluster analysis.** Cluster analysis was performed for the differentially expressed miRNAs in the lung cancer and control groups using cluster software. Differentially expressed miRNAs were screened based on P<0.05 and fold change ≥2 or ≤0.5.

**Prediction and analysis of target genes of differentially expressed miRNAs.** The genes predicted by at least 6 out of 12 commonly used prediction methods of miRNA target genes (miRWalk, DIANA-microTv4.0, miRanda-rel2010, mirBridge, miRDB4.0, miRmap, miRMAP, PicTar2, PITA, RNA22v2, RNAhybrid2 and TargetsCan6.2), based on miRWalk2.0 (14), were considered as target genes.

**Functional enrichment analysis.** Functional enrichment analysis was performed for the target genes of differentially expressed miRNAs. The genes predicted by at least 6 out of 12 commonly used prediction methods of miRNA target genes (miRWalk, DIANA-microTv4.0, miRanda-rel2010, mirBridge, miRDB4.0, miRmap, miRMAP, PicTar2, PITA, RNA22v2, RNAhybrid2 and TargetsCan6.2), based on miRWalk2.0 (14), were considered as target genes.

**Data analysis.** Experimental measurement data were expressed as the mean ± SD. SPSS 17.0 software (SPSS, Inc.) was used for statistical analysis. The log-rank P-values were obtained from a univariate Cox analysis, whereby miRNA expression was evaluated in response to patient survival time. Univariate Cox
analysis also provided the Z-scores, which weighed the importance of the miRNA in response to these parameters. The t-test P-values were obtained from the Student’s t-test, based on the patient vital status. Log2 mean expression of the miRNA in the two survival cohorts was also obtained. The log-rank P-values were obtained from a univariate Cox analysis and survival characteristics of miRNA expression based on the Kaplan-Meier survival curves. The test level was set as \( \alpha = 0.05 \). P<0.05 was considered to indicate a statistically significant difference.

Results

Difference in miRNA expression profile of cancer tissues. The heatmap of gene expression in each group, obtained using the Cluster software, showed the difference in the expression of each gene in the different groups. Cluster analysis was performed for the miRNA expression in 4 cases in lung cancer group and 5 cases in normal group using the Cluster chip technique, and the differential genes were screened by the system according to the parameter setting and grouping, thus obtaining the distribution diagram (Fig. 2A) and list of differential genes. In the diagram with abscissa of log2 (fold change) and ordinate of -log10 (P-value), the data closer to the left and right bottom corresponded to the lower P-value, larger fold change and more significant difference (Fig. 2B). A total of 76 differentially expressed genes were screened, and no gene was upregulated (Table I).

Prediction results of target genes of differentially expressed miRNAs. There were 140,405 target genes predicted by at least 6 out of 12 commonly used prediction methods of miRNA target miRNA, micro ribonucleic acid; NSCLC, non-small cell lung cancer.

genes (miRWalk, DIANA-microTv4.0, miRanda-rel2010, mirBridge, miRDB4.0, miRmap, miRNAMap, PicTar2, PITA, RNA22v2, RNAhybrid2 and Targetscan6.2) based on miRWalk2.0 (Fig. 3).

Enrichment analysis of predicted target genes of differentially expressed miRNAs. GO enrichment analysis and KEGG pathway enrichment analysis were performed for the target genes obtained.

GO enrichment analysis. The analysis of the functions of target genes of differentially expressed miRNAs via GO enrichment revealed that they mainly influenced the binding process of intracellular components to protein, the positive regulation of biological process and the regulation of metabolic process (Table II and Fig. 4).

KEGG enrichment analysis. KEGG pathway enrichment analysis showed that these target genes were mainly enriched in the immunity, gene expression, metabolism and signal...
Figure 4. Top 30 functions of target genes predicted by GO enrichment analysis. The top 30 functions are classified into three categories, i.e., biological processes, cellular components and molecular functions. Among them, 19 functions are related to biological processes which mainly influence the positive regulation of biological processes, metabolic processes and cellular processes. Eight functions are related to cellular components which mainly influence intracellular components, and 3 functions are related to molecular functions which mainly influence protein binding and ion binding. GO, Gene Ontology.

Table II. Top 30 functions of target genes predicted by Gene Ontology enrichment analysis.

Figure 5. Top 30 signaling pathways by KEGG pathway enrichment analysis. The top 30 signaling pathways of the differentially expressed miRNAs were obtained by KEGG enrichment analysis. The size of each dot represents the amount of gene enrichment. The larger the dot, the more genes are enriched. The smaller the dot, the smaller the number of the genes enriched. The color of each dot represents the P-value. The more red the dot, the smaller the P-value. KEGG pathway enrichment analysis showed that these target genes are mainly enriched in the immunity, gene expression, metabolism and signal transduction, among which signal transduction was enriched with the most genes. KEGG, Kyoto Encyclopedia of Genes and Genomes; miRNA, micro ribonucleic acid.
transduction, among which signal transduction was enriched with the most genes (Table III and Fig. 5).

Disease enrichment analysis. The tenth disease enriched was cancer (Table IV and Fig. 6).

Comparison of miRNA-139-5p and miRNA-150-5p relative expression levels between the lung cancer and control group and its influence on prognosis. According to RT-qPCR verification with an expanded sample size, the expression levels of miRNA-139-5p and miRNA-150-5p in lung cancer group were lower than those in control group, in accordance to the GeneChip results, displaying statistically significant differences (P<0.05) (Fig. 2C). The use of online resources (http://www.oncomir.org/) predicted that low-expression miRNA-139-5p in lung squamous cell carcinoma and high-expression miRNA-150-5p in lung adenocarcinoma have a good prognosis (Tables V and VI, Fig. 2D and E).

Discussion

NSCLC is a kind of solid tumor that is often diagnosed in the late stage, due to the lack of specific early symptoms, resulting in fewer opportunities for operation. Moreover, most of the samples in clinical survey are obtained via bronchoscopic small biopsy or cytology, so the number of tumor cells available is small with poor quality. miRNAs, as a kind of biomarkers, have expression dysregulation in the resected primary NSCLC tissues (17), which plays important roles in the classification of lung cancer subtypes, prognosis of patient, and sensitivity to chemotherapy (18,19). In the present study, a comprehensive miRNA expression profile was identified, and abnormally expressed miRNAs in tumor tissues were confirmed, providing references for the in-depth research on the role of miRNAs in occurrence and development of tumors.

According to the systematic analysis of miRNA in various human cancers and 217 types of mammals, the miRNA profile has a surprising amount of information, reflecting the developmental lineage and differentiation status of tumors. miRNAs in tumors are generally downregulated, compared with those in normal tissues, and the miRNA expression profile is valuable for the classification of poorly differentiated tumors (20). The results of this study are consistent with those in the above studies: All of the 76 differentially expressed miRNAs screened were downregulated, and no differentially expressed miRNAs were upregulated. miRNAs are a kind of non-coding regulatory RNAs involved in the occurrence of...
miRNA EXPRESSION PROFILE IN NSCLC

Tumors and they display significant tissue specificity, which can serve as effective biomarkers for tracking the cancer of unknown origin (21). Previous studies have demonstrated that the miRNA expression profile is correlated with the survival of lung adenocarcinoma. Univariate analysis has shown that the high expression of hsa-mir-155 and low expression of hsa-let-7a-2 are correlated with the low survival rate, while multivariate analysis have revealed that hsa-mir-155 is still related to the survival rate, and the miRNA expression profile is a diagnostic and prognostic marker for lung cancer (22). The above results also suggest that the expression of miRNA in NSCLC is different from that of mRNA (23,24). The role of miRNA in the overall survival of patients with NSCLC has been analyzed currently, which may provide valuable information for the treatment of NSCLC (25). However, its expression in lung cancer tissues was less consistent in the previous studies. Whether the lung cancer stage, case type and smoking status affect the results is worthy of further exploration and analysis.

In the present study, five miRNAs were selected and verified via RT-qPCR with an expanded sample size, and it was found that both miR-139-5p and miRNA-150-5p were downregulated.
which is consistent with the GeneChip results. It is also reported that miR-139-5p is significantly downregulated in primary NSCLC tissues and cell lines. On the one hand, the ectopic expression of miR-139-5p significantly inhibits cell growth by suppressing the upregulation of cyclin D1 and p57 (Kip2). On the other hand, miR-139-5p induces apoptosis through upregulating cleaved caspase-3, a key apoptotic gene, and downregulating Bcl-2, an anti-apoptotic gene. In addition, miR-139-5p inhibits cell migration through inhibiting matrix metalloproteinase (MMP)-7 and MMP-9, and it was also found that miR-139-5p inhibits cell proliferation and metastasis promoting apoptosis through targeting oncogenic c-Met, thus playing a key role in lung cancer (27). In primary NSCLC, the miR-139 silencing mediated by histone H3 lysine 27 trimethylation (H3K27me3) enhances the distant lymph node metastasis and histological invasion (lymphatic invasion and vascular invasion) of NSCLC (28). Moreover, miR-139-5p inhibits in vitro proliferation, migration and invasion of lung cancer cells through targeting the insulin-like growth factor 1 receptor (IGF1R) (29). miRNA-150-5p has not been reported in NSCLC in detail, however it has been reported that miRNA-150-5p and miRNA-34c-3p are closely related to the roles of miR-139-5p and miR-150-5p in diagnosis, metabolism, and biological functions of lung cancer cells. Research on the importance of miRNA in pathogenesis. According to previous studies, indicating the individual difference and complexity of miRNA in pathogenesis. According to the verification with an expanded sample size, both miR-139-5p and miR-150-5p are downregulated, thus, deeply exploring their important roles in the occurrence and development of disease and regulation of tumor cell functions has great clinical value in the diagnosis, treatment and evaluation of lung cancer.

Acknowledgements

Not applicable.

Funding

The study was funded by the Fundamental Research for Application Project of the Qinghai Science and Technology Department (project no. 2016-ZJ-778).

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions

YG wrote the manuscript and was responsible for the immunohistochemistry. YG and XS performed PCR. XW and XL were responsible for GeneChip scanning of lung cancer tissues. YG and YX assisted with statistical analysis. All authors read and approved the final manuscript.

Ethics approval and consent to participate

The study was approved by the Ethics Committee of Qinghai Provincial People's Hospital (Xining, China) (approval no. 2015-07); and informed consents were signed by the patients and/or their guardians.

Patient consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
