INTRODUCTION

Fibromyalgia (FM) is a chronic pain condition of unknown etiology, with an estimated prevalence rate of 2% (1). It is characterized by diffuse pain, fatigue, disturbed sleep, the presence of tender points, and functional impairment (2).

The assessment of health status and physical functioning is essential in patients with rheumatic disease and has become an important approach in evaluating outcomes (3, 4). Health status instruments, such as the Health Assessment Questionnaire (HAQ) (5), the Arthritis Impact Measurement Scale (AIMS) (6), and their various modifications, as well as the Fibromyalgia Impact Questionnaire (FIQ) (7) are widely accepted forms for evaluating the clinical severity of disease (8) and the efficacy of different interventions in patients with FM (9).

The aim of this study was to translate the Fibromyalgia Impact Questionnaire (FIQ) into Korean and to evaluate its reliability and validity for use with Korean-speaking patients with fibromyalgia (FM). After translating the FIQ into Korean, we administered it to 55 patients with FM (28 patients filled out the questionnaire again 7 days later) together with a Korean version of the Health Assessment Questionnaire (HAQ) and the Symptom Checklist-90-Revision (SCL-90-R). The tender-point count (TPC) was calculated from tender points identified by thumb palpation. In addition to sociodemographic characteristics, the severity of relevant current clinical symptoms, e.g., pain intensity, fatigue, and morning stiffness, were assessed by 10-cm visual analog scales (VAS). The test-retest reliability was between 0.466 and 0.780 (total 0.778). Cronbach's alpha was 0.800 for FIQ1 (the first assessment) and 0.857 for FIQ2 (the second assessment), indicating acceptable levels of internal consistency for both assessments. Significant correlations were obtained between the FIQ items, the HAQ, the severity of clinical symptoms, and the subscales of the SCL-90-R. In conclusion, the Korean version of the FIQ is a reliable and valid instrument for measuring health status and physical functioning in Korean patients with FM.

Data are presented as mean±SD.

Table 1. Descriptive analysis of demographic and clinical parameters

| Parameter                        | Total (n=55) | Retest (n=28) |
|----------------------------------|--------------|---------------|
| Age (yr)                         | 44.2±12.9    | 40.0±11.4     |
| Education (yr)                   | 10.2±4.7     | 11.8±4.1      |
| Symptom duration (yr)            | 7.5±7.1      | 6.3±5.5       |
| Disease duration (yr)            | 0.6±0.9      | 0.6±0.6       |
| Income (× 10,000 won per month)  | 136.2±85.6   | 144.6±84.5    |

Patient-reported assessments of current functional limitations were collected with the HAQ. The HAQ is a self-administered disability instrument developed for patients with rheumatoid arthritis, and it is used to compare the disabilities of patients with different rheumatic diseases and FM. The HAQ has been translated into numerous languages, including a valid and reliable Korean-language version (14).

Symptom Checklist-90-Revision (SCL-90-R)

This scale includes 90 items that measure 9 clinical subscales and was developed as a measure of general psychiatric symptom severity and as a descriptive measure of psychopathology (15). On a 5-point Likert scale, subjects report the degree to which they have been distressed by symptoms in the past month. The scale has been extensively used and validated in Korean (16).

RESULTS

Descriptive analyses of the demographic and clinical charac-
The characteristics of the patients are shown in Table 1. The mean age of the 55 patients was 44.2 yr (range, 16-62 yr) and the mean disease duration was 0.6 yr (range, 0-2 yr). Twenty-eight patients answered the FIQ again one week after the first administration. Mean values (SD) for FIQ1 (the first assessment) and FIQ2 (the second assessment) were 51.63 (10.79) and 49.24 (12.31), respectively (Table 2). The test-retest reliability was between 0.466 and 0.780 (total, 0.778) for the physical functioning component as well as for the total FIQ and the other components (Table 3). Cronbach’s alpha was 0.800 for FIQ1 and 0.857 for FIQ2, indicating acceptable levels of internal consistency for both assessments.

The correlations between FIQ items and the HAQ, the TPC, and the anxiety and depression subscales of the SCL-90-R are summarized in Table 4. There were statistically significant correlations between the total HAQ score and scores on the physical functioning component of the FIQ and total FIQ. Substantial correlations (p<0.01) were obtained between the anxiety and depression subscales of the SCL-90-R and the anxiety and depression items on the FIQ, with correlation coefficients of 0.432 and 0.373, respectively. Correlations between the TPC and the FIQ items and the total FIQ were rather low, ranging from -0.043 to 0.486. Only the items that addressed the ability of patients to do their job (0.331), fatigue (0.486), morning tiredness (0.294), and the total FIQ (0.433) reached statistical significance (p<0.05).

Correlations between the FIQ items and the severity of current FM symptoms (VAS) are summarized in Table 5. Most of the items were moderately correlated with almost all current FM symptoms.

### DISCUSSION

Physicians have been urged to do more research on FM pathophysiology and treatment. We need a valid and reliable instrument to communicate in the same terms while measuring the status, progress, and outcome of patients with FM, and to compare the results of different trials. In this study, a Korean version of the FIQ was found to be valid and reliable when used in clinical care and research. The translation of an instrument from one language to another usually presents problems, especially if the culture and socioeconomic char-

### Table 3. Test-retest reliability coefficients (Spearman) for the Korean FIQ

| FIQ item       | Spearman coefficient | p value |
|----------------|----------------------|---------|
| Physical functioning | 0.513                | 0.005   |
| No. days felt good     | 0.609                | 0.001   |
| No. workdays missed   | 0.689                | 0.006   |
| Ability to do job     | 0.780                | <0.001  |
| Pain                   | 0.568                | 0.002   |
| Fatigue                | 0.716                | <0.001  |
| Morning tiredness     | 0.611                | 0.001   |
| Stiffness              | 0.466                | 0.012   |
| Anxiety                | 0.704                | <0.001  |
| Depression             | 0.486                | 0.009   |
| Total FIQ              | 0.778                | <0.001  |

### Table 4. Test of the validity of the FIQ (n=55): Spearman correlation coefficients between scores for the FIQ items and for the HAQ, the TPC, and the subscales of the SCL-90-R

| FIQ item       | TPC       | HAQ       | SCL-90-R  |

| Pain                   | 0.616*     | 0.664*            | 0.226*     | 0.318*     | 0.337*  | 0.544*            | 0.672*         | 0.592*          | 0.610*   |
| Fatigue                | 0.438*     | 0.398*            | 0.704*     | 0.598*     | 0.380*  | 0.525*            | 0.373*         | 0.391*          | 0.640*   |
| Morning tiredness     | 0.049      | 0.319*            | 0.461*     | 0.237      | 0.132   | 0.219             | 0.312*         | 0.294*          | 0.297*   |
| Stiffness              | 0.391*     | 0.668*            | 0.325*     | 0.355*     | 0.414*  | 0.580*            | 0.583*         | 0.618*          | 0.620*   |
| Anxiety                | 0.183      | 0.180             | 0.373*     | 0.558*     | 0.767*  | 0.364*            | 0.258*         | 0.353*          | 0.535*   |
| Depression             | 0.140      | 0.313*            | 0.393*     | 0.714*     | 0.692*  | 0.335*            | 0.195          | 0.309*          | 0.544*   |
| Total FIQ              | 0.515*     | 0.664*            | 0.628*     | 0.779*     | 0.702*  | 0.672*            | 0.635*         | 0.662*          | 0.874*   |

*p<0.05, *p<0.01. VAS: visual analog scales.
characteristics of the populations differ. To adapt the FIQ to Korean culture, we modified several questions. In this study, the mean of the total FIQ score was 51.63 for the initial assessment and 49.24 for the second assessment. These scores were somewhat higher than those reported by Burckhardt et al. (7), whose total score was 48.1, and Offenhaecker et al. (12), whose total score was 46.1. The sub-scores obtained for "fatigue" and "morning tiredness" were high in our trial. These elevated sub-scores might have increased the total score.

The test-retest reliabilities for items on the physical functioning component and for the overall FIQ score were 0.513 and 0.778, respectively. In cross-cultural adaptations of the FIQ for Swedish, Hebrew, German, and Turkish populations (10-13), test-retest correlations for the FIQ of 0.62 to 1.00 have been reported. Our test-retest reliability was somewhat less than that of others, but was still respectable. Internal consistency was found to be high for both assessments (0.800 for FIQ1 and 0.857 for FIQ2). This level of consistency is similar to that reported by Sarmer et al. (13), who reported internal consistencies of 0.72 and 0.73, and Buskila et al. (11), who reported internal consistencies of 0.93 and 0.86. Thus, this scale is a coherent, additive instrument, in which an average score for the individual items in each subscale has meaning.

Construct validity was evaluated by correlating the FIQ items with the severity of clinical symptoms (VAS), the TPC, the HAQ, and the subscales of the SCL-90-R. Using the HAQ as the gold standard for evaluating the disability of patients with rheumatic diseases, we found substantial correlations between the total HAQ score and scores on the physical functioning component, as well as the total FIQ. However, the items for fatigue, morning tiredness, stiffness, anxiety, and depression did not correlate with the HAQ. For the original FIQ, Burckhardt et al. (7) found a higher correlation between the FIQ and the AIMS. The AIMS has more specific subscales, including pain, depression, and anxiety, whereas the HAQ assesses difficulties and disabilities in basic activities of daily life and does not deal with those areas. Therefore, the HAQ may not be a valid indicator of health status in patients with FM. The anxiety and depression items of the FIQ correlated significantly with the anxiety and depression subscale of the SCL-90-R, demonstrating satisfactory construct validity in the psychological components of the translated FIQ. The correlation between clinical severity parameters, such as pain intensity, morning stiffness and fatigue, and the FIQ was found to be moderate to high, supporting the construct validity of the Korean version of the FIQ. Similar results have been reported by other authors for translations of the FIQ into other languages (10-13). The relationship between the TPC and the FIQ items was lower than for other clinical parameters. In the Hebrew validation study (11), the correlations between the TPC and the FIQ items ranged from 0.24 to 0.57, and the correlations between the FIQ items and dolorimetry measurements were even higher than with the TPC, ranging from 0.25 to 0.65. Our findings might have been related to low correlations between "subjective" and "objective" parameters. In addition, this difference might be related to the fact that the mean on the TPC for our patients was 11.40, and our patients might not have been as severely affected as the Hebrew-speaking patients.

In conclusion, the Korean version of the FIQ is a reliable and valid instrument for measuring health status and physical functioning in Korean patients with FM.
