ABSTRACT
Cadmium oxide nanoparticles were synthesized with cadmium chloride and sodium hydroxide as starting materials using the co-precipitation method. This study analyses the enhancement of antibacterial activities of cadmium oxide on the addition of silver. The antibacterial activity was carried out in-vitro against two kinds of bacteria: gram-positive bacteria, Micrococcus Luteus and gram-negative bacteria, Escherichia Coli using the well diffusion method. The tested concentration range of cadmium oxide nanoparticles was 100 μm/mL, 150 μm/mL, 200 μm/mL. The results showed that cadmium nanoparticles had an inhibitory effect against both pathogenic bacteria with a zone of inhibition (18, 20, 24 mm) for Micrococcus Luteus and (14, 16, 18 mm) for Escherichia Coli. The antibacterial effect was more prominent against the high concentration of nanoparticles. Cadmium oxide nanoparticles with silver as a dopant excel in different potential applications.

Keywords: Cadmium Oxide, Antibacterial Effects, Zone of Inhibition, Silver, Well Diffusion Method.

INTRODUCTION
Nanomaterials have gained the utmost importance due to their size-dependent properties. To improve the efficiency of the effects of antibacterial activity in various applications research has been conducted. However, due to the toxicity of certain materials, probing their application has been restricted. Inorganic materials with antibacterial effects provide high bacterial resistance and thermal stability. To eliminate the industrial bacteria these nanomaterials could be synthesized and used as an application.1 Nanomaterials could also be used as appropriate alternatives for traditional antibiotics since they are more resistant to pathogenic bacteria. Finding a prompt method to control the development of bacteria and its activity is much needed. Antibiotics with differing mechanism are necessary for alterations in the traditional treatments.2

The synthesis and development of nanoparticles with enhanced antibacterial properties are needed since the emergence of new resistant bacterial strains to present-day antibiotics is a grave public health issue.3 Exploring the productivity of nanomaterials with antibacterial properties may give effective results in the disinfection of bacteria in the environment. Finding a rapid method to control the development of growth is of extreme importance. Nanomaterials display a robust inhibitory effect on a broad spectrum of bacterial strains. In recent years, studies were conducted in exploring the applications of cadmium oxide in optoelectronics, gas sensors, solar cells, transparent electrodes and photoelectrochemical cells.4–7 This study will highlight the enhancement of the antibacterial activity of cadmium oxide nanoparticles on the addition of silver against pathogenic agents, Micrococcus Luteus and Escherichia Coli.

The addition of capping agents is essential to enhance the...
antibacterial activity of nanoparticles. It also improves the efficiency of nanoparticles and materials.\(^9\)

Glycerol is used as the capping agent during the synthesis process.

**EXPERIMENTAL**

**Materials and Methods**

The materials used for the preparation of cadmium oxide and silver (Ag) doped cadmium oxide are cadmium chloride, silver nitrate, sodium hydroxide. All chemicals were of analytical reagent grade and were purchased from Loba Chemie Pvt. Ltd. and Fisher scientific. Double distilled water was used throughout the synthesis process. As-prepared CdO and Ag-doped CdO were synthesized by the co-precipitation method at room temperature with glycerol as the capping agent.\(^{10,11}\) Capping agent plays an essential role in controlling the size of the nanoparticles during synthesis.\(^{12,13}\) A 1.0 M of cadmium hydroxyl solution was prepared by dissolving cadmium chloride (CdCl\(_2\)\(\cdot\)H\(_2\)O) in deionized water under continuous stirring for 1 hour. Doping of silver was done by adding silver nitrate (AgNO\(_3\)) solution to the cadmium hydroxyl solution. Further, to maintain a particular pH, sodium hydroxide was added dropwise to the resultant solution. The precipitated product was filtered, washed several times with deionized water and methanol and dried in an oven.\(^{14}\)

**Microbial Strains and Nutrient Broth Medium**

*Micrococcus Luteus*, gram-positive bacteria and *Escherichia Coli*, gram-negative bacteria, were taken for the evaluation of antibacterial activity with tetracycline as the standard reference. An aseptic laminar chamber, which consists of a wooden box, was cleansed with 70% ethanol followed by irradiation of UV light from a lamp source. For the preparation of nutrient broth, peptone, yeast, sodium chloride, agar and distilled water were added in a particular proportion. This solution was suspended in distilled water of 200mL kept in a 500 ml conical flask which is then stirred, boiled to dissolve then autoclaved at a temperature of 121°C at 15 lbs for a time limit of 15 minutes. In an aseptic laminar chamber, sterile Petri plates were placed and the hot medium was poured on it. Solidification of the medium was done for a time of 15 minutes.

**Agar Well Diffusion Method**

Cadmium oxide nanoparticles were screened for their antibacterial effect against pathogenic bacteria, *Micrococcus Luteus* and *Escherichia Coli* using well diffusion method.\(^{15,16}\) The bacterial cultures were subcultured in the nutrient broth medium. In a test tube containing inoculum, cotton swabs are immersed. These cotton swabs were spread evenly on the Petri plates containing the solidified agar medium.\(^{17}\) Sterile borer was used to make wells of a diameter of 8 mm in each plate. Cadmium oxide nanoparticles were then placed into each well having a concentration of 100, 500 and 200 μg/mL using a micropipette. At a temperature of 37°C, the plates were incubated for 24 hours.\(^{18}\) The zone of inhibition formed around the wells on each plate was taken into account for measuring the antibacterial activity. Tetracycline, a well-known antibiotic was used as a positive control for standard reference.

**RESULTS AND DISCUSSION**

The nanoparticles were synthesized using the co-precipitation technique. The structural properties were studied using the X-ray diffraction technique and the patterns showed sharp and high-intensity diffraction peaks indicating that the sample is of good crystalline nature. Surface morphology and elemental composition analysis were investigated and the results were published.\(^{14,19}\) UV-Vis absorption spectroscopic analysis in diffuse reflectance mode and Fluorescence lifetime studies were also done and reported.\(^{19}\) Since capping agents enhances the antibacterial activity, glycerol was used as a capping agent during the synthesis process.

The antibacterial activity of cadmium oxide nanoparticles is shown in Fig.-1. Since the bacterial strain (*Micrococcus Luteus*) is susceptible to the antibacterial agent (cadmium oxide), a well-defined zone appears around the sample. This zone of inhibition appearing on the agar plate shows the level of inhibitory activity by the nanoparticles. Figure-2 shows the comparison of inhibition zones caused by CdO and CdO:Ag nanoparticles against the growth of *Micrococcus Luteus* and *Escherichia Coli* bacteria.
Cadmium oxide microplates show prominent cell inhibition of 24 mm for *Micrococcus Luteus* and 18 mm for *Escherichia Coli* at 200 μg/mL concentration. Silver-doped Cadmium oxide nanoparticles showed a maximum zone of inhibition of 26 mm for *Micrococcus Luteus*. The most significant effect of the nanoparticle is found for the concentration of 200 μg/mL against *Micrococcus Luteus*. A Higher zone of inhibition is found with gram-positive bacteria compared to that of gram-negative bacteria. The applied concentration in each well has a direct association with the number of cells. The antibacterial effect was more prominent at a higher degree of concentration of nanomaterials in studies done previously. In the present study, the antibacterial activity of CdO and CdO: Ag is higher for the higher concentration of 200 μg/mL. This is also seen in the studies done by Vinod et al.

CdO nanoparticles show significant antibacterial activity due to the generation of reactive oxygen species and the release of Cd\(^{2+}\) ions. The bacterial cell wall experiences oxidative stress due to the reactive oxygen species formed on the surface of the nanoparticles. This stress eventually leads to the death of the bacterial cell. Reactive oxygen species contain hydroxyl radical (OH\(^{-}\)) and superoxide anion radical (O\(_2^−\)) which could damage the DNA and cell membrane. The nanoparticles get attached to the bacteria due to an electrostatic attraction between them. This contact inhibits the growth of bacteria and the formed ROS kills the cell. This inhibitory activity could also be explained due to the reaction between ions discharged from the nanoparticles and thiol groups of proteins present on the cell membrane of bacteria. These cellular proteins then allow the nutrients through the cell membrane. The difference in the antibacterial activity of CdO and CdO:Ag nanoparticles were associated with cell capsular degradation.

Table 1: The Bactericidal Effects of Cadmium Oxide Nanocrystallites.

| Nanoparticle | Microbes           | Zone of Inhibition (mm) | Standard (Tetracycline) |
|--------------|--------------------|-------------------------|------------------------|
|              |                    | 100 µg/mL | 150 µg/mL | 200 µg/mL |
| CdO          | Micrococcus Luteus |     18     |     20     |     24     | 22     |
|              | Escherichia Coli   |     14     |     16     |     18     | 21     |
| CdO:Ag       | Micrococcus Luteus |     18     |     24     |     26     | 24     |
|              | Escherichia Coli   |     15     |     16     |     21     | 22     |

CONCLUSION

The results showed that the zone of inhibition increases on the addition of silver and it is higher for a higher concentration of nanoparticles. This shows the enhancement of antibacterial activity in cadmium oxide nanoparticles on the addition of silver as a dopant. The enhanced antibacterial efficiency observed makes silver doped cadmium oxide nanoparticles a suitable disinfectant for the elimination of industrial bacteria.
