Oncocytic lipoadenoma is a rare tumor, with only 18 cases having been reported since the first in 1998. We encountered a case of oncocytic lipoadenoma presenting as a slowly growing parotid mass in a 71-year-old man. This tumor is characteristically comprised of a mixture of oncocyes and adipocytes. The present case is one of five reported cases of oncocytic lipoadenoma showing sebaceous differentiation. The results of immunohistochemical study with DOG1 antibody supported the origination of this tumor in the striated duct.

**Key Words:** Parotid gland; Lipoadenoma; Oncocytic cell; Sebaceous differentiation; DOG1

Oncocytic lipoadenoma is a rare entity, with only 18 cases having been reported in the literature. Oncocytic lipoadenoma is a benign encapsulated tumor composed of oncocyes and adipocytes, occurring mostly in parotid glands or less frequently in submandibular glands. We herein present a case of parotid oncocytic lipoadenoma with sebaceous differentiation and immunohistochemical study.

**CASE REPORT**

A 71-year-old man presented with a four-year history of a right infra-auricular mass. The mass measured 4×3 cm and was nontender and movable. Head and neck computed tomography revealed a mass with heterogenous density and a fatty component (Fig. 1A). Partial parotidectomy was performed, revealing a solitary well-defined mass measuring 4.2×3.5×2.5 cm with a thin capsule. The cut surface was tan with yellow areas (Fig. 1B).

Microscopically, the mass was encapsulated and surrounded by normal parotid tissue (Fig. 1C). The tumor comprised oncocytic cells and fat cells with mature adipose tissue occupying about 50% to 60% of the tumor. The oncocytic cells were arranged in an acinar or glandular pattern (Fig. 2A) and contained abundant eosinophilic cytoplasm. Some oncocytic cells were smaller in size, with darker cytoplasm and pyknotic nuclei. Scattered sebaceous glands were also present (Fig. 2B). No pleomorphism, mitosis, necrosis, or capsular invasion was observed.

Immunohistochemically, the oncocytic cells were strongly positive for AE1/AE3 (1:1,000, Dako, Glostrup, Denmark) and cytokeratin 7 (1:1,000, Dako). Peripheral cells were stained by p63 (1:1,000, Dako) and cytokeratin 5/6 (1:200, Dako). Epithelial membrane antigen (1:200, Dako) stained the luminal surface and sebaceous glands. The oncocytic cells were negative for smooth muscle actin (1:1,000, Dako) and calponin (1:1,000, Dako). Cytokeratin 14 (1:400, Biogenex, The Hague, The Netherlands) expression was restricted to sites of sebaceous differentiation. An apical-luminal pattern of DOG1 (1:200, Leica, Newcastle upon Tyne, UK) staining was observed in the normal serous acini, while the tumor cells were negative (Fig. 2C, D). Based on the microscopic findings, we rendered a diagnosis...
Oncocytic lipoadenoma was first reported by Hirokawa et al. in 1998. This rare tumor was not mentioned as an entity in the 2005 World Health Organization (WHO) histologic classification of tumors of salivary glands. In the English literature, 18 cases have been reported (Table 1).1-12 There is no gender predilection, and the patient ages range from 7 to 89 years (median of 55.5 years). All reported cases demonstrated benign clinical courses after excision. The universal microscopic finding in the literature was an encapsulated tumor comprising a mixture of oncotic cells and fat cells. So-called dark cells were also common. Uncommon findings as sclerotic and polycystic changes ascribed to chronic involution, squamous metaplasia, lymphoid stroma, and metaplastic bone formation have been reported.1,2 The presence of mitochondria in those oncotic cells was confirmed by both immunohistochemical and ultrastructural studies.7 Phosphotungstic acid hematoxylin staining and antimitochondrial antibody were utilized to demonstrate the presence of mitochondria.3,6-8 Ultrastructural studies also provided evidence that oncotic lipoadenoma may be derived from striated ductal cells based on similar histological features.7 DOG1 expression was found in both normal and neoplastic counterparts of intercalated ducts and acinar cells, whereas striated duct cells were negative.11 The oncotic cells in our case were negative for DOG1, which supports the contention that striated ductal cells were the origin of this tumor.

Differential diagnoses include sialolipoma, oncocytoma, oncocytois, sclerosing polycystic adenosis, and oncotic metaplasia. The latter two entities do not form a discrete tumor mass. Sialolipomas comprise ductal, acinar, basal, and myoepithelial cell components.14 Oncocytomas are also encapsulated tumors with immunohistochemical findings identical to those of oncotic lipoadenomas, but they lack adipose tissue as their component cells. In addition, 20% of patients with oncocytomas have a history of radiation exposure.15 The presence of sclerotic and polycystic change can be reminiscent of sclerosing polycystic adenosis, but oncotic lipoadenomas lack xanthomatous and apocrine change, which is commonly seen in sclerosing polycystic adenosis. In addition, the presence of acini in sclerosing polycystic adenosis can be aided by DOG1 antibody.

Sebaceous differentiation is not an uncommon finding in salivary glands and can be found in sebaceous lymphadenoma, se-
Table 1. Clinical summary of the reported cases of oncocytic lipoadenoma

| Reference          | Gender | Age (yr) | Location         | Size (cm) | Sebaceous differentiation | Follow-up       |

Fig. 2. (A) Oncocytic cells are arranged in an acinar or glandular pattern. (B) The arrows indicate foci of sebaceous differentiation. DOG1 expression is seen in normal parotid acinar cells (C) but not oncocytic cells (D).
baceous adenoma, pleomorphic adenoma, oncocytoma, sialoblastoma, and Warthin tumor.\textsuperscript{15,16} The majority of the reported oncocytic lipoadenomas including our case exhibit sebaceous differentiation.

Lipoadenomas are similar to adenolipomas of the breast, thyroid, and skin in that they all demonstrate a histological mixture of epithelial components and adipose tissue. In contrast to adenolipoma, which is considered to be a hamartoma, oncocytic lipoadenoma is believed to be a true neoplasm. Ilie \textit{et al.}\textsuperscript{6} identified a t(12;14) translocation in their case. An altered \textit{HMGA2} gene rearrangement is more commonly seen in lipoma, pleomorphic adenoma, and leiomyoma.\textsuperscript{6} The cytogenetic findings support oncocytic lipoadenoma as a distinct neoplasm.
