**Keywords:** aerobic, chemoheterotrophic, mesophile, Gram-negative, motile, budding, stalk-forming, *Hyphomonadaceae*, *Alphaproteobacteria*, CSP 2008

The family *Hyphomonadaceae* within the *Alphaproteobacteria* is largely comprised of bacteria isolated from marine environments with striking morphologies and an unusual mode of cell growth. Here, we report the complete genome sequence *Hirschia baltica*, which is only the second a member of the *Hyphomonadaceae* with a published genome sequence. *H. baltica* is of special interest because it has a dimorphic life cycle and is a stalked, budding bacterium. The 3,455,622 bp long chromosome and 84,492 bp plasmid with a total of 3,222 protein-coding and 44 RNA genes were sequenced as part of the DOE Joint Genome Institute Program CSP 2008.

**Introduction**

Strain IFAM 1418T (= ATCC 49814 = DSM 5838 = KCTC 12471) is the type strain of the species *Hirschia baltica*, which is the type species of the genus *Hirschia*. The genus name *Hirschia* Baker 1896 has been applied to a member of the *Astereaceae*, although the type and only species, *Hirschia anthemidifolia* has also been placed in the genus *Iphiona* [1]. The genus *Hirschia* was named in honor of Peter Hirsch, a German microbiologist and expert on budding and hyphal bacteria. The species epithet refers to the Neo-Latin *baltica*, pertaining to the Baltic Sea [2]. IFAM 1418T was isolated in 1982 along with two additional stalk-forming isolates belonging to the same species, IFAM 1408 and IFAM 1415, from a sample of surface water taken from a boat landing in the Kiel Fjord [2].

*H. baltica* reproduces by budding from the tip of a stalk and has a dimorphic life-cycle similar to that described in bacteria belonging to the closely related genus *Hyphomonas* [2]. Newborn swarmer cells are motile by means of a polar flagellum. Swarmer cells differentiate into stalked sessile cells by ejecting the flagellum and synthesizing a stalk at the same pole. The sessile cells reproduce by budding such that motile daughter cells are formed at and released from the tip of the stalk. Here we present a summary classification and a set of features for *H. baltica* IFAM 1418T, together with the description of the complete genomic sequencing and annotation.

**Classification and features**

A representative genomic 16S rRNA sequence of *H. baltica* was compared using NCBI BLAST [3] under default settings (e.g., considering only the high-scoring segment pairs (HSPs) from the best 250 hits) with the most recent release of the Greengenes database [4] and the relative frequencies of taxa and keywords (reduced to their stem
were determined, weighted by BLAST scores. The most frequently occurring genera were *Hyphomonas* (37.8%), *Maricaulis* (29.5%), *Hirschia* (14.3%), *Caulobacter* (7.4%) and *Woodsholea* (3.6%) (74 hits in total). Regarding the four hits to sequences from members of the *Hirschia* species, the average identity within HSPs was 99.3%, whereas the average coverage by HSPs was 98.8%. Among all other species, the one yielding the highest score was *Hyphomonas johnsonii* (NR_024938), which corresponded to an identity of 93.1% and an HSP coverage of 59.6%. (Note that the Green-genes database uses the INSDC (= EMBL/NCBI/DDBJ) annotation, which is not an authoritative source for nomenclature or classification.)

The highest-scoring environmental sequence was FR684125 ('effect ocean acidification upon microbial prokaryotes marine biome fjord coastal water clone 16 07 04A09’), which showed an identity of 89.4% and an HSP coverage of 99.0%. The most frequently occurring keywords within the labels of environmental samples which yielded hits were 'marin' (2.2%), 'microbi' (2.1%), 'water' (2.0%), 'biofilm' (1.9%) and 'sea' (1.6%) (176 hits in total). Environmental samples which yielded hits of a higher score than the highest scoring species were not found. These keywords reflect very well some the ecological and physiological properties reported for strain IFAM 1418T in the original description [2].

Figure 1 shows the phylogenetic neighborhood of *H. baltica* in a 16S rRNA based tree. The sequences of the two identical 16S rRNA gene copies in the genome differ by one nucleotide from the previously published 16S rRNA sequence (AJ421782), which contains one ambiguous base call.

---

**Figure 1.** Phylogenetic tree highlighting the position of *H. baltica* relative to the type strains of the other species within the family *Hyphomonadaceae*. The tree was inferred from 1,332 aligned characters [6,7] of the 16S rRNA gene sequence under the maximum likelihood (ML) criterion [8] and rooted with the neighboring family *Parvularculaceae*. The branches are scaled in terms of the expected number of substitutions per site. Numbers adjacent to the branches are support values from 450 ML bootstrap replicates [9] (left) and from 1,000 maximum parsimony (MP) bootstrap replicates [10] (right) if larger than 60%. Lineages with type strain genome sequencing projects registered in GOLD [11] are labeled with one asterisk, those also listed as 'Complete and Published' (as well as the target genome) with two asterisks [12,13].
Cells of *H. baltica* strain IFAM 1418<sup>T</sup> are rod-shaped, elliptical or ovoid with 0.5 – 1.0 by 0.5 – 6.0 µm in size (without hyphae which have a diameter of about 0.2 µm) (Figure 2) [2]. IFAM 1418<sup>T</sup> cells stain Gram-negative, are motile and strictly aerobic [2]. 1 to 2 hyphae are located polarly and flagellation is monotrichous polar [2]. Cells grow best in artificial sea water with a broad range of NaCl concentrations (Table 1). The strain grows on a broad spectrum of organic compounds as carbon source such as amino acids, organic acids and sugars (Table 1), but not on C<sub>1</sub> compounds [2]. In contrast to its phylogenetic neighbors *H. baltica* strains do not store PHB [2]. Colonies of strain IFAM 1418<sup>T</sup> show a yellow pigmentation whereas strain IFAM 1408 colonies are white [2].

**Chemotaxonomy**

Cell walls of *H. baltica* contain meso-diamonopimelic acid [2]. The main quinone component is Q<sub>10</sub> [2,24]. In the original publications by Schlesner *et al.* [2] and Sittig and Hirsch [24] the fatty acids were separated into non-hydroxy fatty acids and hydroxy-fatty acids. Main cellular non-hydroxy fatty acids are C<sub>18:1 Δ11</sub> (48.8%), C<sub>16:0</sub> (22.1%), C<sub>18:2 Δ5,11</sub> (9.5%), C<sub>16:1 Δ5</sub> (4.6%), and C<sub>14:1 Δ7</sub> (3.2%). Among the hydroxylated fatty acids IFAM 1418<sup>T</sup> 3-OH fatty acids with C<sub>14:1 3-OH</sub> (79%) and C<sub>12:0 3-OH</sub> (15.8%) predominate, which are useful for the discrimination for *H. baltica* from strains of *Hyphomicrobium* and *Hyphomonas* (Figure 1). Kang and Lee [25] were unable to confirm the presence of these hydroxylated fatty acids in *H. baltica*. There are two reports [2,24] on the lipid composition of *H. baltica* and one on the lipids of *H. maritima* [25]. While all confirm the presence of a single phospholipid, phosphatidylglycerol in members of this genus, it is unclear whether these studies were limited to the detection of only phospholipids. There is evidence that *H. baltica* contains five major lipids, of which one is phosphatidylglycerol (B Tindall, unpublished). The remaining four lipids are not phosphate positive, but their R<sub>t</sub> values and staining behavior indicate similarities to a number of the unusual lipids reported from *Hyphomonas jannaschiana* [26,27].

**Genome sequencing and annotation**

**Genome project history**

This organism was selected for sequencing as a part of the DOE Joint Genome Institute Program CSP 2008. The genome project is deposited in the Genomes On Line Database [11] and the complete genome sequence is deposited in GenBank. Sequencing, finishing and annotation were performed by the DOE Joint Genome Institute (JGI). A summary of the project information is shown in Table 2.

**Strain history**

The history of strain IFAM 1418<sup>T</sup> starts with H. Schlesner who independently deposited the strain in two culture collections, ATCC and DSMZ (in 1989).

**Growth conditions and DNA isolation**

The culture of strain IFAM 1418<sup>T</sup> used to prepare genomic DNA (gDNA) for sequencing was obtained directly from the ATCC. ATCC 49814 was grown in Hirschia medium (ATCC medium 1883) at 30°C with shaking.

Evidence codes - TAS: Traceable Author Statement (i.e., a direct report exists in the literature); NAS: Non-traceable Author Statement (i.e., not directly observed for the living, isolated sample, but based on a generally accepted property for the species, or anecdotal evidence). These evidence codes are from of the Gene Ontology project [23].

**Genome sequencing and assembly**

The genome was sequenced using a combination of Illumina and 454 sequencing platforms. All general aspects of library construction and sequencing can be found at the JGI website [28]. Pyrosequencing reads were assembled using the Newbler assembler (Roche). The initial Newbler assembly consisting of nine contigs in two scaffolds was converted into a phrap [29] assembly by making fake reads from the consensus, to collect the read pairs in the 454 paired end library. Illumina GAii sequencing data (50 Mb) were assembled with Velvet [30] and the consensus sequences were shredded into 1.5 kb overlapped fake reads and assembled together with the 454 data. The 454 draft assembly was based on 128.0 Mb 454 draft data and all of the 454 paired end data. Newbler parameters were -consed -a 50 -i 1350 -g -m -ml 20. The Phred/Phrap/Consed software package [29] was used for sequence assembly and quality assessment in the subsequent finishing process. After the shotgun stage, reads were assembled with parallel phrap (High Performance Software, LLC). Possible mis-assemblies were corrected with gapResolution [28], Dupfinisher [31], or sequencing cloned bridging PCR fragments with subcloning. Gaps between contigs were closed by editing in Consed, by PCR and by
Bubble PCR primer walks (J.-F. Chang, unpublished). A total of 55 additional reactions were necessary to close gaps and to raise the quality of the finished sequence. Illumina reads were also used to correct potential base errors and increase consensus quality using a software Polisher developed at JGI [28,32]. The error rate of the completed genome sequence is less than 1 in 100,000. Together, the combination of the Illumina and 454 sequencing platforms provided 150.6 × coverage of the genome. The final assembly contained 333,683 pyrosequence and 12,860,398 Illumina reads.

### Genome annotation

Genes were identified using Prodigal [33] as part of the Oak Ridge National Laboratory genome annotation pipeline, followed by a round of manual curation using the JGI GenePRIMP pipeline [34]. The predicted CDSs were translated and used to search the National Center for Biotechnology Information (NCBI) non-redundant database, UniProt, TIGRFam, Pfam, PRIAM, KEGG, COG, and InterPro databases. These data sources were combined to assert a product description for each predicted protein. Non-coding genes and miscellaneous features were predicted using tRNAscan-SE [35], RNAMMer [36], Rfam [37], TMHMM [38], and signalP [39].

### Genome properties

The genome consists of a 3,455,622 bp long chromosome with a 45% G+C content and a 84,492 bp long plasmid with a 44% G+C content (Table 3 and Figure 3). Of the 3,266 genes predicted, 3,222 were protein-coding genes, and 44 RNAs; 35 pseudo-genes were also identified. The majority of the protein-coding genes (71.6%) were assigned a putative function while the remaining ones were annotated as hypothetical proteins. The distribution of genes into COGs functional categories is presented in Table 4.

### Notable features of the *H. baltica* genome sequence

**H. baltica** genome is enriched in TonB-dependent receptors

TonB-dependent receptors are outer membrane proteins that function in the energy-dependent uptake of macromolecules, including siderophores and vitamins, that are too large to be taken up by passive diffusion. The genome sequences of *C. crescentus* and *H. neptunium* contain large numbers (63 and 43, respectively) of TonB dependent receptors [40,41]. One possibility is that the presence of many TonB-dependent receptors is a common feature among bacteria belonging to the order Caulobacterales. Indeed, the annotation of the *H. baltica* genome sequence suggests that there are 46 TonB-dependent receptors. The presence of many TonB-dependent receptors may be part of the adaptations that have allowed the *Caulobacterales* to not only inhabit, but also thrive in low-nutrient environments.
Table 3. Genome Statistics

| Attribute                  | Value     | % of Total |
|----------------------------|-----------|------------|
| Genome size (bp)           | 3,540,114 | 100.00%    |
| DNA coding region (bp)     | 3,172,944 | 89.63%     |
| DNA G+C content (bp)       | 1,599,770 | 45.19%     |
| Number of replicons        | 2         |            |
| Extrachromosomal elements  | 1         |            |
| Total genes                | 3,266     | 100.00%    |
| RNA genes                  | 44        | 1.35%      |
| rRNA operons               | 2         |            |
| Protein-coding genes       | 3,222     | 98.65%     |
| Pseudo genes               | 35        | 1.07%      |
| Genes with function prediction | 2,337  | 71.65%     |

| CRISPR repeats             | not reported |          |

**H. baltica** genome contains known regulators of the cell cycle

A recent bioinformatic analysis of genes controlling the dimorphic cell cycle within the *Alphaproteobacteria* suggests the circuitry for cell-cycle control is largely conserved [42]. The conservation of 14 key proteins that function in the regulation of the cell cycle in *C. crescentus* was addressed among the *Alphaproteobacteria* with sequenced genomes, including three bacteria belonging to the *Caulobacteriales*. All of the regulatory proteins were conserved among the genomes of the *Caulobacteriales* with one notable exception: DivJ, a histidine kinase, is absent in the *H. neptunium* genome.

Expanding the analysis to include 8 additional bacteria belonging to the *Caulobacterales*, including *H. baltica*, we find that all 14 regulatory proteins are conserved with the exception of DivJ, which is absent only from the *H. neptunium* and *H. baltica* genomes. The fact that most developmental regulators are conserved in the budding bacteria *H. neptunium* and *H. baltica* as well as the non-budding bacteria belonging to the *Caulobacteriales* suggests that regulation of the cell cycle is evolved prior to the separation of the budding and non-budding bacteria in the *Caulobacteriales*. The finding that DivJ is absent from *H. neptunium* and *H. baltica* but present in the closely related non-budding *Maricaulis maris* and *Oceani-caulis alexandrii* (Figure 1) is an intriguing observation, although the significance of this finding remains unknown.

**H. baltica** genome contains genes for holdfast synthesis and attachment

Bacteria belonging to the order *Caulobacterales* are known for the ability to produce a polar polysaccharide, termed holdfast, which mediates strong adhesion to surfaces (For review see [43]). Notably, extracellular polysaccharides from some of the stalked bacteria sequester metals [44,45], a feature that could be used to remediate environments affected by metal toxicity. The genes required for the synthesis [46,47] and anchoring [48] of the holdfast have been identified and characterized in *C. crescentus*. The holdfast synthesis and anchor genes are largely absent from the genome of *H. neptunium*, which does not produce a polar holdfast (Figure 4 and [41]). The genome sequence of *H. baltica* revealed that the genes predicted to be involved in polar holdfast synthesis are present (Figure 4). Furthermore, a holdfast on *H. baltica* cells was readily detected using a fluorescent wheat germ agglutinin lectin using the procedure detailed in [44] (Figure 4). The holdfast of *H. baltica* is found at the cell pole opposite the stalk of the mother cell and is responsible for the formation of star-shaped cell aggregates known as rosettes in cell culture (Figure 4). This finding, coupled with the observation that other species of *Hyphomonas* produce detectable holdfasts [49], suggests the ability to synthesize holdfast is a conserved feature among the *Hyphomonadaceae* family and the loss of the holdfast synthesis and anchoring genes in *H. neptunium* was a recent evolutionary event.
Figure 3. Graphical circular map of the chromosome (plasmid not shown). From outside to the center: Genes on forward strand (color by COG categories), Genes on reverse strand (color by COG categories), RNA genes (tRNAs green, rRNAs red, other RNAs black), GC content, GC skew.
Table 4. Number of genes associated with the general COG functional categories

Figure 4. Holdfast anchor (hfa) and synthesis (hfs) gene cluster conservation is depicted among *C. crescentus*, *H. baltica* and *H. neptunium*. Presence of holdfast genes is correlated to the ability to detect polar holdfast polysaccharide using fluorescent wheat germ agglutinin lectin. The *H. neptunium* genome contains only hfsAB and fails to make a polar polysaccharide. In contrast, the *H. baltica* genome contains all essential hfs and hfa genes and produces a holdfast.
Concluding Remarks
The completion of the *H. baltica* genome sequence is expected to provide a valuable resource for understanding the biology of stalked budding bacteria with a dimorphic life cycle. Further comparative genomic analyses (especially as more bacteria belonging to the *Caulobacterales* are sequenced) are likely to provide insights regarding the evolution, mechanism, and advantages underlying processes such as budding, and stalk synthesis. Understanding stalk biosynthesis is of particular interest as the ability of these structures to transport nutrients [50,51] could likely be exploited to facilitate the uptake of toxic compounds from contaminated water sources.
