Abstract

\textbf{Context:} Osteopontin (OPN) is a matrix phosphoprotein expressed by a variety of tissues and cells, including the immune system and the nervous system. Previous studies have shown that OPN may have a role in neurodegenerative diseases, including multiple sclerosis, Parkinson’s disease, and Alzheimer’s disease.

\textbf{Objectives:} The present study aimed to systematically review studies investigating the role of OPN in amyotrophic lateral sclerosis (ALS) patients or the disease animal model.

\textbf{Evidence Acquisition:} We searched the Cochrane Library, PubMed, Web of Science, and Scopus to find relevant articles published up to January 20, 2019. Both human and animal model studies of ALS were considered.

\textbf{Results:} A total of nine articles (four human studies and five animal model studies) were included. Two of the human studies reported that the CSF levels of OPN were higher among ALS patients compared to controls. The other two human studies found that OPN levels in cortical neurons did not differ significantly between ALS cases and the non-neurological control group. One of the studies found that the expression level of OPN in astrocytes was similar between ALS patients and the control group, but the level of microglial OPN significantly increased in ALS cases. Four of the animal model studies reported that the expression of OPN mRNA in spinal cord microglia significantly increased during the disease progression. The remaining animal model study found that OPN was selectively expressed by fast fatigue-resistant and slow motor neurons (MNs), which are resistant to ALS, and that the OPN expression was low among fast-fatigable MNs.

\textbf{Conclusions:} Prompt microglial activation is a hallmark pathology of ALS, and OPN is among the most widely expressed proteins by these activated glial cells. Therefore, OPN might have a role in ALS pathogenesis. The existing evidence is not sufficient to justify whether OPN has a neurotoxic or neuroprotective role in ALS. We encourage researchers to investigate the role of OPN in ALS pathogenesis more extensively.

\textbf{Keywords:} Amyotrophic Lateral Sclerosis, Osteopontin, SPP1, Systematic Review

1. Context

Amyotrophic lateral sclerosis (ALS) is a devastating, progressive neurodegenerative disease that causes muscle weakness, atrophy, spasticity, and eventually death. Degeneration of both upper motor neurons and lower motor neurons with astrogliosis and microgliosis is the pathological hallmark of ALS (1). The exact cause of ALS is still unknown. Based on the available evidence, genetic factors, oxidative stress, mitochondrial dysfunction, neurofilament dysfunction, excitotoxicity, apoptosis, and proinflammatory cytokines contribute to ALS pathogenesis (2).

Growing evidence indicates that neuroinflammation plays an important role in the pathogenesis of neurodegenerative diseases, including ALS (3-7). Activated glial cells, particularly microglia and astrocytes, and T lymphocytes are the major cell populations involved in neuroinflammation (3, 8).

Osteopontin (OPN) is a matrix phosphoprotein expressed by a variety of tissues and cells, including the immune system and the nervous system. Immune cells, such as macrophages and T lymphocytes, are important sources of OPN during inflammatory processes. Previous studies have shown that OPN may have a role in neurodegenerative diseases, including multiple sclerosis (MS), Parkinson’s disease, Alzheimer’s disease, and frontotemporal dementia (9, 10). It was reported that OPN was selectively expressed in alpha motor neurons (\(\alpha\)-MNs), which are the...
most vulnerable neurons in ALS (11, 12). Therefore, it may also play a role in the pathogenesis of ALS.

2. Objectives

Few studies have evaluated the OPN expression in ALS patients or the ALS experimental model and compared them with controls. Here, we aimed to systematically review studies investigating the role of OPN in ALS or its animal model.

3. Search Strategy

We searched the Cochrane Library, PubMed, Web of Science, and Scopus to find relevant articles published up to January 20, 2019. The searched terms used in this study were: (ALS OR MND OR motor-neuron-disease OR motor-neurone-disease OR motor-neurone-diseases OR motor-neuron-diseases OR amyotrophic-lateral-sclerosis OR progressive muscular atrophy OR progressive-spinal-muscular-atrophy OR primary-lateral-sclerosis OR motor neuronopathy OR motor neuronopathy OR lou-gehrig's-disease) AND (“osteopontin” OR “OPN” OR “bone sialoprotein I” OR “BSP-1” OR “BSP 1” OR “BSP1” OR “BSPI” OR “BN-SP” OR “early T-lymphocyte activation” OR “ETA-1” OR “ETA 1” OR “ETA1” OR “secreted phosphoprotein 1” OR “SPP-1” OR “SPP 1” OR “SPP1” OR “SPPI” OR “Rickettsia resistance” OR “Ric”). Moreover, we manually screened the reference lists of the included studies and related reviews, and tracked studies that had cited them through the Google Scholar to find eligible articles. Only articles published in English were included. This paper was written according to the preferred reporting items for systematic reviews and meta-analyses (PRISMA) guidelines.

4. Study Selection and Data Extraction

Both human and animal model studies of ALS were considered. The exclusion criteria were: (1) studies on animals other than rodents; (2) studies classified as case reports, case series (if included less than five patients), narrative reviews, systematic reviews, expert opinions, and educational reports, or conference abstracts; and (3) in vitro studies. The following data were extracted from the included studies: first author and year of publication, location, study design, study population characteristics, specimen, method, endpoints, and relevant main findings. The quality of the included human studies was assessed using the Newcastle-Ottawa scale (13). Moreover, the quality of the animal model studies was evaluated using the systematic review center for laboratory animal experimentation (SYRCLE) risk of bias tool (14).

5. Results

Overall, 85 unique articles were retrieved, of which six were selected for full-text eligibility assessment. One study was excluded (had not evaluated osteopontin in ALS patients), and four additional articles were identified via reference screening. Finally, nine articles were included (Figure 1). No study was excluded because of poor quality (Supplementary file appendices). The summary of the included studies is shown in Table 1 and Table 2.

5.1. Human Studies

Four human studies examining OPN in ALS patients and controls were identified (Table 1) (12, 15,17). Two of the human studies measured the level of OPN in the CSF of sporadic ALS patients and controls (15, 16). Both studies reported that the CSF levels of OPN were higher among ALS patients compared to controls. The control group in von Neuhoff et al.’s study included patients with different neurological disorders (15), while none of the control subjects in Varghese et al.’s study had a history of neurological problems (16).

The other two human studies examined tissue samples of the central nervous system with the IHC method (12, 17). Both of these studies found that OPN levels in cortical neurons did not differ significantly between ALS cases and the non-neurological control group (12, 17). Silva et al. found that the expression level of OPN in astrocytes was similar between ALS patients and the control group, but the level of microglial OPN significantly increased in ALS cases (17).

5.2. Animal Model Studies

OPN was evaluated in five ALS animal model studies (18-22). Four of the studies investigated the OPN expression in spinal cord microglia, of which one also examined the microglial OPN expression in the brain stem and the cortex tissue (Table 2). All four studies reported that the expression of OPN mRNA significantly increased during the disease progression. One of the studies found an increased OPN expression during presymptomatic, early symptomatic, and end-stage disease (18). However, the other three studies reported an increased OPN expression only during symptomatic and end-stage disease (19-21). In Nikodemova et al.’s study (20), the OPN expression in cortical microglia was not significantly different from that in wild-type control mice.
One of the studies examined the OPN expression in the spinal cord tissue of mice, focusing on the expression status of α-MNs (22). The authors found that OPN was selectively expressed by fast-fatigue-resistant (FR) and slow (S) MNs, which are resistant to ALS (22). On the other hand, the OPN expression was low among fast-fatigable (FF) MNs (22). Moreover, they realized that extracellular OPN-positive granules gradually began to appear around the time of disease onset, and the number of these extracellular OPN deposits increased significantly at end-stage disease (22). The majority of these granules were detected within or attached to spinal cord microglia (22). They also ablated the OPN gene in ALS mice models to examine whether the role of OPN was neuroprotective or neurotoxic. The authors found that compared to SOD1G93A/OPN+/+ and SOD1G93A/OPN−/− mice, delayed disease onset and significantly accelerated disease progression was observed in SOD1G93A/OPN−/− mice.

Table 1. Summary of Human Studies of OPN in ALS

| Study | Specimen | ALS | Control | Method | Endpoints | Findings |
|-------|----------|-----|---------|--------|-----------|----------|
| Von Neuhold et al. 2002 (35) | CBF | Sporadic (35); | 55.0 ± 10.3; | 55 ± 10.1; | IELISA; MS | Identification of disease-specific CBF biomarkers in ALS-CSF compared to the control CBF, but the results were not statistically significant. |
| Varghese et al. 2005 (36) | CBF | Sporadic (36); | 45 ± 34; | 45 ± 34 | IELISA; MS | To determine the OPN expression in ALS-CSF. |
| Silva et al. 2005 (37) | Tissue (occipital lobe) | Sporadic | 56 ± 7.4 | 56 ± 7.4 | IBC | In normal subjects, the OPN expression did not differ significantly between ALS cases and normal controls or the HIV-ANI group. |
| Yamamoto et al. 2007 (38) | Tissue (brain and spinal cord) | Normal, | 76-90 | 76-90 | IBC | The OPN expression in the human spinal cord, the primary sensory and motor cortex, was not significantly different between ALS patients and normal controls. |

Table 2. Summary of ALS Animal Model Studies of OPN

| Study | Animal Model | Intervention | Method | Endpoints | Findings |
|-------|--------------|--------------|--------|-----------|----------|
| Chito et al. 2008 (39) | SOD1G93A, SOD1WT | Gene expression | Microglia purified from the spinal cord | Realtime PCR | Differences in gene expression during disease progression. |
| Chito et al. 2011 (40) | SOD1G93A, SOD1WT | Gene expression | Microglia purified from the spinal cord | Realtime PCR | Differences in gene expression during disease progression. |
| Nikodemova et al. 2010 (41) | SOD1G93A and SOD1WT | Gene expression | Microglia purified from the brain stem, spinal cord, and cortex | Realtime PCR | Differences in gene expression during disease progression. |
| Norton et al. 2014 (42) | SOD1G93A | Gene expression | Microglia purified from the spinal cord in the lumbar segments | Realtime PCR | Differences in gene expression during disease progression. |
| Mortiuk et al. 2014 (43) | SOD1G93A, SOD1WT | Gene and protein expression | Spinal cord tissue | Immunostaining, Western blot | The OPN expression was high among ALS-resistant MNs (FR and S MNs), but low in FF MNs. |

6. Conclusions

Here, we systematically reviewed in vivo studies investigating OPN changes in ALS patients or animal models. Four human and five animal model studies met the inclusion criteria (12, 15-22). Eight of the papers were published after 2012 (12, 15-17, 19-22), and the remaining one was published in 2008 (18). The OPN expression was examined in CSF, glial cells (microglia and astrocytes), and neurons (cortical and spinal cord).

Two of the human studies found higher levels of OPN in the CSF of ALS patients compared to controls (15, 16). The other two human studies indicated that OPN levels remained unchanged in cortical neurons (12, 17). Yamamoto et al. found that OPN-immunoreactivity in each neuron was significantly reduced in both the primary motor cortex and the spinal cord of ALS patients (12). One of the studies found that compared to normal controls, the intensity of OPN-positive neurons was significantly reduced in the spinal ventral horn of ALS patients (12). Another one of the studies reported that microglial OPN levels significantly increased in brain tissues from ALS patients compared to normal samples (17). The same study did not find any signifi-
cant difference between ALS patients and controls regarding the OPN level in astrocytes (17).

All the animal model studies focused on gene expression differences between SOD1<sup>G93A</sup> mice and controls (18-22). Three of the animal model studies reported that the level of the OPN expression in spinal cord microglia was significantly higher in SOD1<sup>G93A</sup> mice than in controls (18-20). All the five animal model studies found that the OPN expression in spinal cord microglia of SOD1<sup>G93A</sup> mice significantly increased during disease progression (18-22). One of the studies investigating the mRNA levels of OPN in cortical microglia found no significant difference between wild-type and SOD1<sup>G93A</sup> mice (20). One study had investigated the OPN expression in α-MNs and the role of the OPN gene in disease onset and progression (22). The authors found that the OPN expression was high among ALS-resistant MNs but low in FF MNs, which degenerate early in ALS (22). They also found that the ablation of the OPN gene in SOD1<sup>G93A</sup> mice delayed disease onset, but accelerated the disease progression and had a minimum impact on the survival rate (22).

Microglia are the resident macrophage cells of the central nervous system and are involved in various physiological and pathological conditions, including neurodegenerative diseases (23). Loss of motor neurons in ALS leads to the prompt activation of microglia and astrocytes (7). Activated microglia can promote neurodegeneration by the expression of reactive oxygen species and several proinflammatory cytokines (23). It can also exert neuroprotective effects by suppressing local inflammation and debris clearance, as well as by producing and releasing a plethora of trophic factors (24, 25).

Both human and animal model studies of ALS showed that compared to controls, OPN levels significantly increased in microglia of the disease group (17-21). An increased OPN expression in microglia can have both inflammatory and anti-inflammatory effects. In vitro studies demonstrated that OPN might promote the survival of microglia under stress conditions (26). OPN reduces the expression of inducible nitric oxide synthase and the NO release from microglia (26-28). It may also act as a T-helper type 1 cytokine and promote inflammation (29).

OPN is selectively expressed in large α-MNs, which are the most vulnerable neurons in ALS (11, 12, 22). Within α-MNs, the OPN expression is low among FF MNs, which degenerate early in ALS (22). Morisaki et al. (22) found that while disease onset was delayed in SOD1<sup>G93A</sup>/OPN<sup>-/-</sup> mice, disease progression was significantly accelerated in them compared with SOD1<sup>G93A</sup>/OPN<sup>+/+</sup> and SOD1<sup>G93A</sup>/OPN<sup>+/+</sup> mice. Yamamoto et al. (12) realized that within neurons, OPN-immunoreactivity was reduced considerably in MNs and pyramidal neurons of ALS patients compared to normal subjects. These findings indicate that the OPN expression in neurons may have neuroprotective properties. There is some evidence that OPN may enhance the survival and proliferation of neuronal cells (30-33).

Prompt microglial activation is a hallmark pathology of ALS, and OPN is among the most widely expressed proteins by these activated glial cells. Therefore, OPN might have a role in ALS pathogenesis. The existing evidence is not sufficient to justify whether OPN has a neurotoxic or neuroprotective role in ALS. We encourage researchers to investigate the role of OPN in ALS pathogenesis more extensively.
