Effect of Synthetic Polymers on tRNA Nanoparticle Formation

Abstract

In this review, we have examined the effects of several synthetic nanoparticles such as poly (ethylene glycol) PEG (PEG-3350, PEG-6000), methoxypoly(ethylene glycol) antracene (mPEG-anthracene), methoxypoly (ethylene glycol) poly (amidoamine) (mPEG-PAMAM-G3), (mPEG-PAMAM-G4) and poly (amidoamine) (PAMAM-G4) on tRNA structure and dynamics. Atomic force microscopic (AFM) images and spectroscopic data were analysed and the effects of synthetic polymer complexation on tRNA stability, aggregation and particle formation are discussed. Hydrophilic and hydrophobic contacts were dominated in the polymer-tRNA complexation and the overall binding constants showed that the order of binding is PEG-6000 > PAMAM-G4 > PEG-3350 > mPEG-PAMAM-G4 > mPEG-PAMAM-G3 > mPEG-anthracene. The morphology of polymer-tRNA complexes showed major aggregation and nanoparticle formation of tRNA, in the presence of synthetic nanoparticles.

Keywords: PEG; Dendrimer; tRNA; Particle formation; Spectroscopy; AFM

Introduction

Synthetic polymers play a major role in therapeutic drug, protein and gene delivery systems [1-6]. Among synthetic polymers (Scheme 1), poly (ethylene glycol) and its derivatives show potential applications in gene and drug delivery due to their solubility, nontoxicity and biocompatibility [1-3]. Dendrimers (Scheme 1) are also unique synthetic macromolecules of nanometer dimensions with a highly branched structure and globular shape with strong affinity towards DNA and RNA complexation [4-10]. It has been shown that synthetic polymers induce significant changes in DNA and RNA solubility and structure under given conditions [8-20]. Synthetic polymers are also used to transport miRNA and siRNA in vitro [11-24]. PEGylation of synthetic polymers such as dendrimers is shown to reduce toxicity and increase biocompatibility and DNA Transfection [6,7,9]. It is well demonstrated that synthetic polymers induce DNA and RNA aggregation and particle formation [25-29]. However, not much of investigation on the effect of synthetic polymers on tRNA structure and dynamic has been reported. Therefore, it was of interest to review and compare the effects of several synthetic polymers on tRNA aggregation and particle formation that are reported in the literature [25,26].

In the following section we compare the binding of tRNA to several synthetic polymers such as PEG-3350, PEG-6000 and mPEG-anthracene, mPEG-PAMAM-G3, mPEG-PAMAM-G4 and PAMAM-G4 at physiological conditions. The data obtained from multiple spectroscopic measurements and AFM microscopic images will be analysed and the effects of various synthetic polymers on tRNA aggregation and particle formation are reported here.

Scheme 1: Chemical structures of PEG, mPEG-PAMAM-G3 and PAMAM-G4.
AFM images and morphology of synthetic polymer-tRNA complexes

Major tRNA aggregation and particle formation were observed in the presence of PEG, mPEG-anthracene, dendrimers and PEGylated dendrimers [25,26]. In the case of PEG-3350, PEG-6000 and mPEG-anthracene, the mica surface was covered by small complexes of various shapes (Figure 1-panel A). In each case the average height and average volume of the complexes were estimated. The PEG-3350 complexes had an average height of 0.75±0.12 nm (n=143) and an average volume of 61 nm³ (Figure 1-panel A). PEG-6000 complexes were doubled in height compared to the PEG-3350 ones, average height of 1.3±0.3 nm (n=208) and average volume of 520 nm³ (Figure 1-panel A). Finally, mPEG-Anthracene complexes had an average height of 0.59±0.2 nm (n=108) and an average volume of 252 nm³ (Figure 1-panel A). Assuming a molecular weight of 27 kDa and a density of 1 g/cm³, each tRNA molecule should occupy a volume of 45 nm³. Hence the PEG-3350 complexes contain in average one tRNA molecules, the anthracene complexes five molecules and the PEG-6000 complexes ten molecules (Figure 1-panel A). The tRNA aggregation and particle formation in the presence of PEG and mPEG-anthracene were very similar to those of PEG-DNA complexes recently reported [21,22].

Similarly in the cases of dendrimers and PEGylated dendrimers, the mica surface was covered by a layer that attributed to a mixture of free dendrimer, free pegylated dendrimers and free tRNA (Figure 1-panel B). On the top of this layer several round aggregates were observed (Figure 1-panel B). In each case the average height and average volume of the aggregates were measured. The mPEG-PAMAM-G3 complexes had an average height of 0.29±0.18 nm (n=50) and an average volume of 80 nm³ (Figure 1-panel B). The mPEG-PAMAM-G4 complexes had an average height of 0.54±0.35 nm (n=50) and an average volume of 104 nm³ (Figure 1-panel B). Finally, PAMAM G4 complexes showed the best defined aggregates with an average height of 0.43±0.13 nm (n=100) and an average volume of 102 nm³ (Figure 1-panel B). As one can see major aggregation and particle formation of tRNA were observed in the presence of these synthetic polymers, particularly in the cases of PEG-6000 and PAMAM-G4 nanoparticles (Figure 1-panel A & B).

Binding sites of synthetic polymers with tRNA

FTIR spectroscopy is widely used to characterize the binding of ligand to DNA and RNA [25-29]. Synthetic polymer complexes with DNA and tRNA via hydrophilic, hydrophobic contacts, groove binding and phosphate interaction [25-29]. The infrared spectra and difference spectra of the free tRNA showed major alterations of tRNA in-plane vibrations and the backbone phosphate asymmetric and symmetric stretching bands [30-35], upon polymer complexation (Figure 2-panels A and B). Low concentration (0.125 mM) of synthetic polymers PEG-3350, PEG-6000, mPEG-PAMAM-G3, mPEG-PAMAM-G4 and PAMAM-G4 induced minor changes of tRNA vibrational frequencies, while at high polymer content (1 mM) major alterations of tRNA in-plane and the backbone vibrational frequencies (Figure 2-panels A and B). The major intensity increases were associated with the guanine at 1698 (guanine N7), uracil at 1660 (uracil O2 and adenine at 1609 cm⁻¹ (adenine N7) in the difference spectra of PEG-3350, PEG-6000, mPEG-anthracene, mPEG-PAMAM-G3, mPEG-PAMAM-G4 and PAMAM-G4 complexes of tRNA (Figure 2-panels A and B, diff., 1 mM). The observed intensity changes were attributed to polymer interactions with tRNA guanine N7, uracil O2 and adenine N7 sites [25,27]. Similarly, increase in the intensity of the backbone PO2 vibrations was observed due to synthetic polymer-P O2 interaction (Figure 2-panels A and B, diff., 1 mM).

Hydrophilic and hydrophobic contacts in polymer-tRNA complexes

A major shifting of the OH stretching of the free PEG at about 3430 cm⁻¹ to a lower frequency in the infrared spectra of PEG-tRNA complexes was attributed to the hydrophilic interaction between PEG and tRNA polar groups. Similarly, the shifting of the NH stretching vibration at 3280 cm⁻¹ in the spectra of the free dendrimer and pegylated dendrimers was due to the hydrophilic contacts between dendrimers terminal NH2 groups and the tRNA polar groups [25,27]. However, hydrophobic interactions between tRNA and synthetic polymer were characterized by the shifting of the polymer antisymmetric and symmetric CH2 stretching vibrations, in the region of 3000-2800 cm⁻¹. The CH2 bands of
the free PEG at 3000, 2990, 2940 cm\(^{-1}\) exhibited a minor shifting, while the CH\(_2\) vibrations related to mPEG-PAMAM-G3 located at 2946, 2884 and 2859 cm\(^{-1}\); for free mPEG-PAMAM-G4 at 2942, 2876 and 2856 cm\(^{-1}\) and free PAMAM-G4 at 2969, 2940 and 2834 cm\(^{-1}\) shifted to higher frequencies in the spectra of dendrimer-tRNA complexes. The shifting of the polymer antisymmetric and symmetric CH\(_2\) stretching vibrations in the region 3000-2800 cm\(^{-1}\) of the infrared spectra suggests the presence of minor hydrophobic interactions via dendrimer hydrophobic cavities and tRNA hydrophobic groups [25,27].

Figure 2: FTIR spectra and difference spectra [(tRNA solution + polymer solution) - (tRNA solution)] in the region of 1800-600 cm\(^{-1}\) for the free tRNA and its synthetic polymer complexes with PEG-3350, PEG-6000 and mPEG-anthracene (panel A) and for mPEG-PAMAM-G3, mPEG-PAMAM-G4 and PAMAM-G4 (panel B) in aqueous solution at pH 7.3 with various polymer concentrations (0.125 and 1 mM) and constant tRNA content (12.5 mM).
Synthetic polymer and tRNA conformation

The CD spectra of tRNA and its synthetic polymer complexes are shown in Figure 3. The CD of the free tRNA is composed of four major peaks at 209 (negative), 221 (positive), 240 (negative) and 269 nm (positive) (Figure 2). This is consistent with CD spectra of double helical RNA in A conformation [36,37]. As polymer complexes formed, a major increase in molar ellipticity of the band at 209 nm occurred and the amplitude of the band at 240 was reduced, while the intensity of the band at 269 decreased at high polymer concentration (Figure 3, panel A). However, no major shifting was observed for the band at 269 nm in the spectra of polymer-tRNA complexes (Figure 3, panel A&B). This is due to the presence of tRNA in A-conformation both in the free state and in the synthetic polymer-RNA complexes. This is also consistent with the infrared results that showed free tRNA in A-conformation with IR marker bands at 1698 (G), 1241 (PO₂), 864 and 810 cm⁻¹ (ribose-phosphate) with no major shifting of these bands in the polymer-tRNA complexes (Figure 2, panels A and B).

The reduced intensity of the band at 269 nm, in the spectra of polymer-tRNA complexes together with the major intensity changes of the band at 209 and 221 nm were attributed to the aggregation and particle formation of tRNA, in the presence of PEG-3350, PEG-6000, mPEG-anthracene (Figure 3, panel A) and mPEG-PAMAM-G3, mPEG-PAMAM-G4 and PAMAM-G4 (Figure 3, panel B). The extent of decrease of intensity was much pronounced in the case of PAMAM-G4 nanoparticle, where tRNA aggregation and particle formation were observed (Figure 3, panel B). This is consistent with AFM images of the synthetic polymer-tRNA complexes that showed major tRNA aggregation and particle formation by PAMAM-G4 nanoparticles (Figure 1, panel B).

Stability of synthetic polymer-tRNA complexes

The calculated binding constants of synthetic polymer-tRNA complexes by UV-visible spectroscopic method [38] showed $K_{\text{PEG-3350-tRNA}} = 1.9 \times 10^4$ M⁻¹, $K_{\text{PEG-6000-tRNA}} = 8.9 \times 10^4$ M⁻¹ and $K_{\text{mPEG-anthracene}} = 1.5 \times 10^4$ M⁻¹ and $K_{\text{mPEG-G3}} = 5.3 \times 10^3$ M⁻¹ (Figure 4, panels A&B) [25-27]. Stronger polymer-tRNA complexation formed by PEG-6000 than PEG-3350 and mPEG-anthracene, while PAMAM-G4 forms more stable complexes with tRNA than those of PEGylated dendrimers with the order of binding PEG-6000>PAMAM-G4>PEG-3350>mPEG-PAMAM-G4>mPEG-PAMAM-G3>mPEG-anthracene (Figure 4, panels A&B) [25-27]. This is indicative of PEG forms stronger complexes than mPEG, dendrimers and PEGylated dendrimers. Similarly, stronger complexes form with larger PEG than smaller polymer. This is also consistent with the conclusion that synthetic polymer-tRNA interaction is more hydrophilic than hydrophobic occurred between polymer and tRNA polar groups. This conclusion can be supported by the argue that PEG with mostly hydrophilic character forms stronger complexes with tRNA, while mPEG-anthracene, with mostly hydrophobic nature forms weaker tRNA complexes. Similarly, PAMAM-G4 which has more cationic NH₂ groups (64 NH₂ groups) than those of mPEG-PAMAM-G4 (32 NH₂ groups) and mPEG-PAMAM-G-3 (8 NH₂ groups) forms stronger complexes than PEGylated dendrimers (Figure 4, panels A&B) [39,40]. The results showed that hydrophilic interaction is a major part of synthetic polymer-tRNA complexation.

Fluorescence spectra of synthetic polymer-tRNA and the number of binding sites

As tRNA is a weak fluorophore, the titration of mPEG-anthracene was done against various tRNA concentrations, using mPEG-anthracene excitation at 330-350 nm and emission at 400-450 nm [41,42]. When mPEG-anthracene interacts with tRNA, fluorescence may change depending on the impact of such interaction on the mPEG-anthracene conformation or via direct quenching effect [43]. The decrease of fluorescence intensity of mPEG-anthracene has been monitored at 420 nm for mPEG-anthracene-RNA systems. The plot of $F_0 / (F_0 - F)$ vs $1/[tRNA]$ is shown in Figure 5A. Assuming that the observed changes in fluorescence come from the interaction between mPEG-anthracene and polynucleotides, the quenching constant can be taken as the binding constant of the complex formation. The binding constant obtained was $K_{mPEG-anthracene-DNA} = 8.2 (\pm 1) \times 10^3$ M$^{-1}$ (Figure 5A). The association constant calculated for the mPEG-anthracene-RNA adduct suggests low affinity mPEG-anthracene-tRNA, which is consistent with the UV results discussed above. The $n$ values obtained in Figure 5, suggest that tRNA also interacts with fluorophore via hydrophobic interactions, which is consistent with our infrared spectroscopic results discussed (hydrophilic and hydrophobic contacts).

The number of binding sites occupied by mPEG-anthracene molecule on tRNA ($n$) was calculated from $\log ([F_0 - F] / F) = \log K_s + n \log [tRNA]$ for the static quenching [44-49]. The linear plot of $\log ([F_0 - F] / F)$ as a function of $\log [RNA]$ is shown in Figure 5A'. The $n$ values from the slope of the straight line was 1.3 for mPEG-anthracene-RNA adduct (Figure 5A'). It seems that about one binding site is occupied by the PEG and mPEG-anthracene on tRNA in these polymer-tRNA complexes.

Conclusion and Outlook

In this review the bindings of several synthetic polymers with tRNA were characterized and several major points are concluded. Synthetic polymers bind tRNA through a major hydrophilic interaction and a minor hydrophobic contact. The binding is mainly through polymer polar groups (OH, NH$_2$ and C-O) and tRNA bases and the backbone-phosphate group. The order of binding is PEG-6000 > PAMAM-G4 > PEG-3350 > mPEG-PAMAM-G4 > mPEG-PAMAM-G3 > mPEG-anthracene. Synthetic polymer complexation induces major tRNA aggregation and particle formation, while tRNA remains in A-conformation. More investigations of similar nature should be done, using AFM, TEM and SEM microscopic images in order to determine the ultrastructure and morphology of synthetic polymer-RNA complexes.
