Abstract
Earthworms had a mechanism of antibacterial. The research aimed to observe Lumbricus rubellus, Eisenia foetida, Nereis sp. antibacterial activity against Salmonella thyposa, Staphylococcus aureus, Enterococcus faecalis in vitro compared to ampicillin antibiotics. All the worms extracted using ethyl acetate extraction and tested their MIC. The compound of amino acids of the worms was analyzed by HPLC and nanodrop. Lumbricus rubellus was the best anti-bacteria activity followed by Eisenia foetida and Nereis sp, but these activities less than ampicillin antibiotic. Observations with SEM showed these worms extract caused cell leakage in all of these bacteria. Protein content with Nanodrop testing revealed the highest protein content was Lumbricus rubellus (21.75 ppm) followed by Eisenia foetida (21.32 ppm) and Nereis sp. (20.98 ppm), as well as for amino acids levels, there were Lumbricus rubellus (24.66%), Eisenia foetida (22.78%), Nereis sp. (18.37%). From the 15 amino acids detected, all of the worms had the same sequence of fourth the highest amino acids (Glutamate, Aspartate, Leucine, Arginine) and fourth the lowest amino acid levels (Methionine, Hystidin, Tyrosin, Glisan). It had not been tested amino acid sequences of antibacterial compounds of these worms (Lumbricin 1: Phe-Ser-Lys-Tyr-Glu-Arg in Lumbricus rubellus worms, Fetidin 1: Ala-Met-Val-Ser-Ser and Fetidin 2: Ala-Met- Val-Gly-Thr in the Eisenia foetida worm, Hemerythrin: His-Glu-Asp in Nereis sp).

Keywords: Antibacterial, Earthworm, In vitro, MIC

1. Introduction
Nonburrowing earthworm annelids (Lumbricus rubellus, Eisenia foetida,) and sandworm (Nereis sp,) are known as feed fish; high nutritional value and protein content which triggering immune innate of fish. Non burrowing annelids mostly red, reddish in color, 10-15 cm length, life span not more than 28 month (Nagalakshmi, Prakash, & Aysha, n.d.). In nature, these earth worms are detritus feeder, decomposed organic matter in soil and fertilized the soil (Ansari & Ismail, 2012) as well as fungal repellent by contact with mucus secretion or coelomic
fluid (Plavšin, Velki, Ečimović, Vrandečić, & Ćosić, 2017). Earthworms antibacterial testing in vitro have been done by using the chloragocytes, a class of free coelomocytes existing only in annelids (Valembois, Roch, & Lassegues, 1988) dried worms (Prakash & Gunasekaran, 2011), mucus of the earthworms (Andleeb et al., 2016), coelomic fluid of the earthworm (Roch, Lassegues, & Valembois, 1991) (Nicholas & Hodgkin, 2002) or by innate immune defenses system challenged (Nicholas & Hodgkin, 2002); (Hancock & Diamond, 2000), injecting bacteria into coelomic of living earthworms (Lass, Roch, & Valembois, n.d.). Antibacterial of the earthworms included in non-ribosomal synthesized peptides in which peptides elaborated in bacteria (Hancock & Diamond, 2000).

Local wisdom of Java society has been used earthworm as typhus fever medication. Fresh worms are washed, disposed of stomach contents, chopped, mixed in cooking as foodstuff ingredient, given to the typhoid fever patient. Another way is dried earthworm, put in capsules and taken as medicine, while others use worm extract mixed with extracts of other natural ingredients into herbs for typhoid drugs. However, using ethyl acetate extract earthworm against Salmonella thyposa, bacteria causing typhoid fever, Enterococcus faecalis and Streptococcus aureus in vitro is little data. Salmonella spp.

Caused a wide spectrum of disease in humans and animals and effectively avoid killing by the host immune system (Gunn & Miller, 1996). Staphylococcus aureus, Gram positive bacteria, has ability into adapt to different environments and can be said as intrinsic virulence (Lowy, 2003), able to form biofilm in situ (Stewart & William Costerton, 2001), produces a wide variety of toxins, emetic or not emetic in primate (Argudín, Mendoza, & Rodicio, 2010). Enterococcus faecalis has the numbers of virulence factor (Stuart, Schwartz, Beeson, & Owatz, 2006). The aim of the research was to know the ability ethyl acetate extract of earthworms (Lumbricus rubellus, Eisenia foetida, Nereis sp) against Salmonella thyposa, Streptococcus aureus, Enterococcus faecalis in vitro.

2. Materials and Methods

Earthworms

All the worms were obtained alive. Lumbricus rubellus and Eisenia foetida were obtained by digging and hand sorting collecting of CV Alam Organik, Sukun, Malang, East Java, Indonesia. Nereis sp worms were obtained by digging and hand sorting on the coast of Pasir Putih, Situbondo East Java, Indonesia. Identification of the worms used special features morphology. Eisenia foetida had yellow and dark red rings along its body, a flat tail tip, and pink in dorsal part, white-reddish in ventral part, orange in tail and body length of about 7 cm, diameter of 3 mm. The length of Lumbricus rubellus earthworms were about 10 cm, reddish-skinned, slightly transparent and segmented in circular sections (annulus). The dorsal prostomium Nereis sp consists of 2 antennas, 2 septum, and 4 relatively large sized eyes. The samples of the research can be seen at Figure 1. All the worms were cleaned by washing in running water, drained, sliced, washed again with running water, drained, dried in an oven (Memmert, Germany produced 2015) at 50°C for 12 hours, blended and stored in a tightly closed container.

Earthworm’s ethyl acetate extraction

The worm’s powder were mixed with ethyl acetate (Sigma) (1:20, 12 hours, stirred with magnetic stirrer) and filtered. The filtrates were concentrated with a rotary evaporator (the IKA RV-10 produced IKA ASIA, Malaysia, in 2014) at a temperature of 50°C for 30 minutes, stored in a sterile vial bottle.

Protein examination

Testing of worm extract protein concentrations using Nano Drop (type ND 1000, serial number 9189, Thermo Fisher
Absorption solution of worms extracts at $\lambda$ 280 nm for estimating protein concentration with correction absorption of $\lambda$ 260 nm (presence of nucleic acid). 280/260 absorption ratio was a correction factor in the table. Protein content of mg / mL = Absorption at $\lambda$ 280 x correction factor x dilution.

**Total Nitrogen of the worms**
Examination of total nitrogen of the worms extracts based on total N of the samples, were carried out by the Kjeldhal method (Kjelmaster buchi k-375 Grobest Corporation Co. Ltd., Thailand, 2006). 0.5 gram sample was added to 25 mL H$_2$SO$_4$ and a catalyst into the Kjeldahl flask, heated to a clear greenish color.

**Amino acids content of the worms**
Amino acids of the worms extracts were determined using HPLC (HPLC RF 20 A type ICI with ODS column, Shimadzu, Kyoto, Japan, 2007)), 50 μL sample solution mixed with 50 μL buffer. 5μL of that mixture was taken and stored on an auto sampler vial between positions 1-44. Another line with the OPA reagent work solution was placed at position 45 on the auto sampler. 5μL sample was injected into an HPLC column. In order for the amino acid separation process works well, each column chromatography process always balance with the A buffer which programmed into the gradient file of the K-45 gradient programmer.

**Bacterial Testing**
*Salmonella thyphosa, Streptococcus faecalis* and *Enterococcus faecalis* were obtained from the collection of the Laboratory of Microbiology, Faculty of Medicine, Brawijaya University. Bacterial density was determined by Optical Density (Shimadzu, $\lambda$ 600 nm) in TSB (OXOID) and then poured in Muller Hinton Agar (OXOID) to obtain a bacterial density of $10^6$. This bacterial density was used to measure antibacterial activity of the worms extracts by disc method.

**Anti-Bacterial Testing**
Antibacterial activity of the worms extracts were examined using Minimum Inhibitory Concentration (MIC). Muller Hinton Agar (OXOID) media on petri dishes were planted with $10^6$ densities these bacteria with poured method. The worm extracts were made in concentrations of 0 ppm, 10 ppm, 100 ppm, 1,000 ppm, 10,000 ppm, and 100,000 ppm with 10% DMSO as a control and 100 ppm ampicillin as a positive control. Sterile disc paper (Φ 6 mm, OXOID) is dipped in each test solution and placed on the media. Incubation was carried out for 24 hours at 37 °C. antibacterial activity of the worms extracts were measured by measurement clear zone around the blank disk. All treatments were repeated 4 times.

**Minimum Bactericidal Concentration (MBC) Measurement**
The test was performed by preparing six tubes, each of tube containing 10 ml of sterile TSB (OXOID) medium in which filled worms extracts 0 ppm, 12,500 ppm, 25,000 ppm, 50,000 ppm, 100,000 ppm and 100 ppm ampicillin as a positive control. 1 mL of the bacterial suspension was added in those tubes and mixed (vortex mixer IKA, Germany, 2015). Optical density of the worms were measured using visible UV spectrophotometer (Spectroquant Pharo 300, Germany, 2011) at $\lambda$ 600 nm, incubated at 37 °C. The measurement was repeated at the sixth hour. MIC value was determined by observe decreasing absorbance of worms extract concentration in the first time. 0.1 mL those MIC value were planted on 5 mL sterile TSB (OXOID), incubated in 37°C, 24 hours. The MBC value was determined by the absence of turbidity (transparent) of those broths at the lowest concentration.
**Bacterial morphology Observation**

Form the tubes of MIC bacterial suspension was observed with a light microscope (Olympus CX22, Japan, 2014) and Scanning Electron Microscopy (TM 3000 Hitachi with Swift ED 3000 X-Ray Microanalysis, Japan, 2016). The bacteria were fixed in 2% glutaraldehyde solution for 3 hours at 4°C. The suspension then washed using phosphate buffer pH 7.4, followed by dehydration using ethanol concentration (20%, 50%, 70%, 96%, absolute) each of these for 15 minutes. Suspension smeared on the cover glass and continued smearing with gold-palladium as coating and observed into the SEM device.

3. **Result**

Examination the number of peptides using Nano drop and proteins content based on N total can be seen in Table 1. Lumbricus rubellus worms had more peptide bonds, followed by Eisenia foetida and Nereis sp. The same results were shown from the number of N Total with the Kjeldhal method. The amino acid profile of worms extract can be seen in Table 2. The total amino acid of Lumbricus rubellus worm was the highest compared to the worms Eisenia foetida and Nereis sp, as well as the levels of each amino acid detected. All worms were dominated by aspartate and glutamate acids and had small amounts of Methionine, Histidine, Tyrosine and Serine amino acid.

All worms also had the highest number of amino acids was hydrophobic amino acid (Ala, Iso, Leu, Met, Val), followed anionic amino acid (aspartic acid and glutamate acid), cationic amino acid (Arg, His, Lys) and hydrophilic uncharged amino acid (Gly, Ser, Threo, Tyr). Proline, Tryptophan, Asparagine, Glutamine, Cysteine were not detected due to lack of standard amino acids in the test laboratory. Non-polar amino acids of Nereis worm were 6.91%, Lumbricus rubellus 8.99% and Eisenia foetida 8.31%. The number of anionic amino acids for Nereis sp was 5.14%, Lumbricus rubellus 7.03% and Eisenia foetida 6.3%. The cationic amino acids Nereis sp worms are 3.53%, 4.2% in Lumbricus rubellus and 4.19% in Eisenia foetida.

Clear zones as a sign of anti-bacterial activity from all samples at concentrations of 0 ppm, 10 ppm, 100 ppm, 1,000 ppm, 10,000 ppm worms extract were not observed. The clear zone of worm extract only seen at worms extract 100 000 ppm, which clear zones small enough compared with the amphyciline 100 ppm. The clear zones of these worms extracts at 100 000 ppm can be seen in Table 3. From Table 3 can be observed that all worm extracts at 100 000 ppm had a better anti-bacterial activity to inhibit Salmonella thyposa and Staphylococcus aureus. Enterococcus faecalis resisted from all worms extracts.

Minimum Bactericidal Concentration testing of worm extracts at concentration of 100 000 ppm on TSB media still showed turbidity but not for amphyciline 100 ppm as shown in Table 4. Observation using light microscopy (Figure 2, 4, 6) confirmed anti-bacterial activity of those extract worms as shown MBC. Antibacterial activity of those worms extracts in 100 000 ppm were weak antibacterial. However, from the three earthworms, Lumbricus rubellus had the highest anti-bacterial activity. Observations using electron microscope (Figures 3, 5, 7) showed that the death of those bacteria were thought due to bacterial cell wall leakage.
Table 1. The worms extract protein content

| The worms extract | Nanodrop (mg/mL) | N Total (% db) | Amino acid (%) |
|-------------------|------------------|----------------|---------------|
| Nereis sp.        | 20.98 ± 1.01     | 42 ± 2.47      | 18.37         |
| Lumbricus rubellus| 21.75 ± 1.11     | 50 ± 2.69      | 24.66         |
| Eisenia foetida   | 21.32 ± 1.07     | 44 ± 2.36      | 22.78         |

Table 2. The worms extract amino acids profile

| No | Amino acid  | Nereis sp | Lumbricus rubellus | Eisenia foetida |
|----|-------------|-----------|--------------------|-----------------|
| 1  | Glutamate   | 2.95 %    | 4.16 %             | 3.70 %          |
| 2  | Aspartic    | 2.19 %    | 2.87 %             | 2.60 %          |

4. Discussion

Amino acid profile of the worms (Table 3) showed the biggest content was hydrophobic amino acids (6.91% in *Nereis*, 8.99% and 8.31% in *Lumbricus rubellus* and *Eisenia foetida*). Anionic amino acid was the second amount (5.14%, 7.03%, 6.3% in *Nereis, Lumbricus rubellus* and *Eisenia foetida*), and then hydrophilic uncharged amino acid (3.29%, 4.45%, 4.09% in *Nereis, Lumbricus rubellus* and *Eisenia foetida*). The last content was cationic amino acid (3.53%, 4.2%, 4.12% in *Nereis, Lumbricus rubellus* and *Eisenia foetida*). Antibacterial peptides of these worms can be detected from amino acid residue. In this research, it did not examine so far.

Worm antibacterial was cationic peptides. Form Table 3 showed *Lumbricus rubellus* had the highest cationic amino acid. Hancock & Lehrer (Hancock & Lehrer, 1998) reviewed that characteristics of cationic peptides were excess lysine and arginine residue; Rich in proline and tryptophan; Rich in histidine residue; Amphiphatic molecules, it consist of 12-45 amino acid residue. The main site of action cationic peptide antimicrobial was in cytoplasmic membrane and carpet effect (peptide cluster at the membrane surface and cause disruption of cell permeability). In the Gram negative, the peptides initially interact with lipopolysaccharide, a highly anionic outer membrane, and glycolipid and then disrupt the membrane locally.

Researched of Yeaman & Yount (Yeaman & Yount, 2003) showed hydrophobic amino acid able to damage the permeability of bacterial cell membranes
three times stronger than hydrophilic amino acid. The ability of worms as an antimicrobial was caused by electrostatic interactions. Cationic peptides antimicrobial (Lys and Arg) bound in phosphate groups of membrane cell, caused leaking of membrane cell and then cell lysis as seen at SEM photograph in the Figure 3, 5,7. 50% or more of the amino acids were hydrophobic, these will interact with bacterial membranes causing membrane damage (Hancock & Diamond, 2000). Cell death of bacteria caused by membrane pore formed by electrostatic interaction between peptide antimicrobial with phospholipid in membrane bilayer; cytoplasmic membrane dysfunction caused loss of ion and then cessation of respiration; inhibition peptidoglycan and macromolecules synthesis as well as inhibition of intracellular function (Hancock & Lehrer, 1998). Research of (Gunn & Miller, 1996) showed lipopolysaccharide of lipid A in membrane bilayer of Salmonellas thyposa bind with cationic antimicrobial peptides causing cell death. Bacterial cell membrane damage that causes cell death also observed by Carson (Carson, Mee, & Riley, 2002) in which tea tree oil rich in terpenoid caused Staphylococcus aureus membrane damage and followed by cell lysis. The same phenomenon was observed by Jung (Jung et al., 2008). The cell death of Staphylococcus aureus begin with membrane cell damaged due to membrane interaction with silver ion.

Nereis muscles contain abundant quantities of soluble, sarcoplasmic, high affinity Ca\(^{2+}\) binding proteins (SCBPs). SCBP is a single polypeptide chain of 174 amino acids, including single residues of glutamine and histidine, 2 tyrosine, and 3 tryptophan (Collins, Coxti, & TheibertS, n.d.). Another researcher showed Nereis contains peptide antimicrobial bromo tryptophane, in which specific for estuarine organism (Tasiemski et al., 2007). (Lumbricus rubellus had Lumbricinin antimicrobial, a proline-rich antimicrobial peptide (Cho, Park, Yoon, & Kim, n.d.); (Wang, Wang, Zhang, Qu, & Yang, n.d.). Fetidin, antimicrobial peptide composed of amino acid Gly-Thr-Lys-Thr-Leu-Ala-Ser-His-Ser-Iso obtained from coelomic Eisenia foetida extraction (Lasseues, Milochau, Doignon, Pasquier, & Valembois, 1997).

Gram-positive cells, exposure to antimicrobial peptides caused water and ion flow increasingly, especially ion K\(^{+}\) and osmotic disturbed (Yeaman & Yount, 2003) However, it did not apply in Enterococcus faecalis as seen in Figure 6 and 7. Enterococcus faecalis was a ubiquitous microorganisms, grows normally in GI human and animals, high heat tolerance and had ability to growth in adverse environment (Giraffa, 2002). It had a proton pump that can maintain pH homeostasis; disrupted growth only in pH up to 11.5 (Stuart et al., 2006). Enterococcus faecalis resistant to vancomycin (MICs, 32 to 64 ug/ml) but not to teicoplanin (MIC, .0.5 ug/ml) (Sahm et al., 1989). Ethyl acetate these earthworms extract were crude extracts, the main component was cationic peptide in the form unpurified so it not showed effective antibacterial against Enterococcus faecalis.

A little number of clear zones (Table 3) and a high number of MIC value (Table 4) indicated that all of worms ethyl acetate extract were not effective antibacterial against Salmonella thyposa, Staphylococcus aureus, and Enterococcus faecalis in vitro. The research with the same result was showed by The research of Andleeb (Andleeb et al., 2016) showed that antimicrobial of mucus extract of the worm was lower than the mucus. The same result had been shown by the search of (Plavšin et al., 2017) Coelomic extract of Eisenia foetida did not showed antibacterial effect against some of fungal, but it showed different result in using coelomic fluid. (Lasseues et al., 1997) and (Milochau, Lassègues, & Valembois, 1997) showed the antimicrobial of worms in coelomic fluid. Coelomycites in coelomic fluid was the natural responses of bacterial
challenge (Procházková et al., 2011). In this research used dried of worms, so coelomic fluid was little enough. Liu et al (Liu, Ju, & Xia, 2014) showed induced bacterial can trigger peptide antibacterial in the tissue of earthworms, but it only produced by earthworms adult (Cho et al., n.d.).

5. Conclusion
Ethyl acetate worms extract of Lumbricus rubellus, Eisenia foetida, Nereis sp were antibacterial ineffective against Salmonella thyposa, Sterptococcus aureus, Enterococcus faecalis in vitro. From the worms, ethyl acetate extract of Lumbricus rubellus was the best antibacterial. Enterococcus faecalis was the resistant microorganism of the worm antimicrobial ethyl acetate extract.
