Background: Protracted armed conflicts not only shape political, legal, and socio-economic structures, but also have a lasting impact on people’s human migration. In 2017, the United Nations High Commissioner for Refugees reported an unprecedented number of 65.6 million individuals who were displaced worldwide as a result of armed conflicts. To date, however, little is known about these people’s mental health status. Therefore, we conducted a systematic review of the prevalence of psychiatric disorders among forcibly displaced populations in settings of armed conflicts.

Methods: We undertook a database search using Medline, PsycINFO, PILOTS, and the Cochrane Library, using the following keywords and their appropriate synonyms to identify relevant articles for possible inclusion: “mental health,” “refugees,” “internally displaced people,” “survey,” and “war.” This search was limited to original articles, systematic reviews, and meta-analyses published after 1980. We reviewed studies with prevalence rates of common psychiatric disorders—mood and anxiety disorders, psychotic disorders, personality disorders, substance abuse, and suicidality—among adult internally displaced persons (IDPs) and refugees afflicted by armed conflicts.

Results: The search initially yielded 915 articles. Of these references 38 studies were eligible and provided data for a total of 39,518 adult IDPs and refugees from 21 countries. The highest prevalence were for reported for post-traumatic stress disorder (3–88%), depression (5–80%), and anxiety disorders (1–81%) with large variation. Only 12 original articles reported about other mental disorders.

Conclusions: These results show a substantial lack of data concerning the wider extent of psychiatric disability among people living in protracted displacement situations. Ambitious assessment programs are needed to support the implementation of sustainable global mental health policies in war-torn countries. Finally, there is an urgent need for large-scale interventions that address psychiatric disorders in refugees and internally displaced persons after displacement.

Keywords: mental health, psychiatric disorders, refugees, internally displaced people, epidemiology, war, systematic review
INTRODUCTION

“War should be understood as an actual, intentional, and widespread armed conflict between political communities […] defined as those entities which either are states or intend to become states […]” (1). Whether considered from a philosophical, sociological, or legal perspective, war remains one of the most complex and devastating human enterprises (1). In 2016, according to the Department of Peace and Conflict Research at the University of Uppsala, 51 ongoing armed conflicts were reported worldwide and well over 100,000 people were killed in organized violence (2). Beyond this sole number, the entire ecology of war has dramatically changed over the past two decades. Altogether less frequent, armed conflicts have reached low- and middle-income countries (LMICs) more frequently and become predominantly intrastate and disproportionately protracted in nature (3).

Intrastate, irregular, and protracted armed conflicts have drastically influenced recent figures of global displacement (4). In its 2017 Global Trends Report, the United Nations High Commissioner for Refugees (UNHCR) announced an estimated 10.3 million newly displaced individuals—Syria being the most affected country—and an overall number of 65.6 million forcibly displaced people worldwide (5). While UNHCR refugee statistics have demonstrated a substantial stabilization of the number of out-of-country refugees over the past 10 years, numbers of internally displaced people (IDP) have reached unparalleled levels representing more than 65% of the displaced population globally (6). In 2016 alone, conflict and violence gave rise to 6.9 million new IDPs, which disproportionately came from LMICs.

Organized violence has profound and catastrophic structural effects on already fragile developing countries, where 84% of the world’s refugees live (5); political and economic structures are undermined, laws are overstepped, fundamental rights of individuals are often abused, and healthcare services shattered (3, 7, 8). Quantifying the magnitude of these consequences on people undoubtedly remains an intricate challenge (7). However, numerous public health studies in complex humanitarian settings have shown that armed conflicts critically affect mental health (6, 9–11).

Reliable assessments of mental health needs in humanitarian settings should be viewed as a public health priority. In fact, no mental health policies can be efficiently implemented without an accurate assessment. This seems particularly true today: numbers of global displacement related to conflicts are increasing dramatically, common camp-based models of displaced populations are becoming outdated—60% of IDPs are currently living in urban areas without any international protection—and the heavy burden of psychiatric diseases in LMICs are being acknowledged (3, 12).

Based on the assumption that conflict-affected populations will be traumatized, most studies have singularly focused on PTSD whilst largely ignoring other psychiatric disorders. Considering psychological trauma or depression as main research objectives in settings of generalized violence or unresolved conflicts is a major intellectual misapprehension. It fails to appreciate the extent of global repercussions on mental health, that is, the risks of intense psychological distress in otherwise healthy individuals and increased neuropsychiatric diseases or the worsening of chronic mental illnesses due to an aggravated lack of medical resources (13–15). Additionally, these risks interact with several environmental factors that directly influence mental health such as forced evacuation of homes and separation from family members, interpersonal tensions, or loss of employment opportunities (13–15).

Two previous systematic reviews have evaluated prevalence rates of psychiatric disorders in refugee populations. Steel et al. (16) conducted a systematic review and meta-analysis finding higher prevalence rates of PTSD and depression in conflict-displaced refugees globally. Another review from Ezard et al. (17) observed the rates of substance abuse among refugees displaced by conflict and reported on associated risk factors and outcomes. There is still a paucity of data on the epidemiology of mental illness in populations displaced by armed conflicts. This is especially true for less common psychiatric disorders such as psychotic disorders. Therefore, we conducted a systematic review to summarize the prevalence of common psychiatric disorders, as well as more severe—uncommon—psychiatric disorders in IDPs and refugees still residing in LMICs. We also report on the methods of assessing mental illness, number, and types of traumatic events, and the duration of the displacement experience.

METHODS

To ensure the highest standardized methods of reviewing process, the conduct of this research was guided by the PRISMA guidelines for systematic reviews and meta-analyses (18).

Search Strategy

We undertook a sequential database search using MEDLINE via PubMed, PsycINFO, PILOTS, and the Cochrane library of systematic reviews. Medical Subject Headings with related text-based search terms were used with a combination of the following terms and concepts: “mental health,” “refugee,” “prevalence,” and “war.” In addition, articles indexed by “internally displaced people” were identified using the method of single keywords. Similarly, in the PILOTS database, an online index collecting the literature on PTSD and mental health consequences of traumatic events (19), a combination of single keywords and their synonyms was used to identify pertinent studies: “mental health,” “refugee,” “internally displaced people,” “war,” “prevalence,” and “humanitarian settings.” Relevant gray literature (unpublished articles, international reports, or non-governmental epidemiological surveys) was retrieved through an internet search. Lastly, citations from relevant articles and systematic reviews were also screened. This initial process yielded an overall number of 915 articles: 902 were generated through systematized database search, while 13 were retrieved from the gray literature and article/systematic review bibliographies (Figure 1).
Inclusion and Exclusion Criteria

Studies were considered eligible for the review if they assessed the prevalence of common mental disorders among internally displaced people and refugees afflicted by armed conflicts in a war region or unstable country. Original articles written in English, French, and German were included. The issue of internally displaced or refugee children and adolescents should be addressed separately (20–23) and therefore, an age limit of
greater than or equal to 16 was selected as an inclusion criterion. We also limited our research to articles published after 1980 as interests about global mental health in war-torn countries emerged after 1980 when mental health progressively became an integral part of the field of public health (24). The status of conflict and displacement were other important inclusion criteria. We only included studies that reported results from or were completed in countries where conflicts were unresolved at the time of investigation and if study samples consisted of populations in protracted displacement situations. However, the UNHCR definition of “protracted refugee situations”—at least 25,000 people gathered outside of their country of residence for greater than or equal to 5 consecutive years—was not considered as part of the selection process (25).

In this context, we did not restrict article selection according to the numbers of IDPs or refugees and years of displacement, since many authors did not report this information. Furthermore, we only included studies from LMICs defined according to the Gross National Income per capita classification proposed by the World Bank (26). We did so for two principal reasons. On the one hand, mental disorders among resettled refugees in Western high-income countries (HIC) have been investigated to a great extent in the light of PTSD, depression, and anxiety disorders (27). On the other hand, contextual factors such as a lower likelihood of being exposed to an ongoing conflict and its myriad consequences, resettlement in stable accommodations, greater economic or educational opportunities uniquely distinguish resettled refugees in HIC from displaced populations in LMICs (28). Finally, case reports, qualitative studies, systematic reviews, meta-analyses, and articles reporting consequences of natural disasters on mental health were excluded.

In order to precisely define the term refugee, the 1951 Refugee Convention was considered (29, 30): a refugee is a person who has crossed the international borders of his or her country of origin due to a “well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion,” and “is unable to, or owing to such fear, is unwilling to avail himself of the protection of that country.” Related to this, internally displaced people are “persons or groups of persons who have been forced or obliged to flee […] their homes […], in particular as a result or in order to avoid the effects of armed conflict, situations of generalized violence, violations of human rights […] or human-made disasters, and who have not crossed an internationally recognized state border” (12).

Study Selection and Data Extraction
Study selection and data extraction were completed independently by two reviewers (LL & AA) in duplicate; disagreements between them were resolved by a third reviewer (NM). The following study characteristics were extracted: type and year of study, regionality, sample size, sampling method (when available), and type of assessment method of psychiatric disorders. With regard to assessment, different potential situations were examined: clinical diagnosis provided by a trained interviewer using various methods such as the Harvard Trauma Questionnaire [HTQ; (33)], or the Hopkins Symptom Checklist-25 [HSCL-25; (34)], and mental health evaluation by means of a self-administered questionnaire. We extracted prevalence rates of mental disorders but scores of scales were not used. More importantly, we did not restrict the extraction to disorders such as PTSD, depression, or anxiety disorders but included also general neuropsychiatric illnesses and, when applicable, general distress. Additional data extracted covered: type, year, and country of conflict (the total duration of conflict was inferred); status, country, and length of displacement; average number of experienced and/or witnessed traumatic events; mean age of study participants, and male to female ratio. In order to compare countries in terms of severity of conflicts, levels of generalized violence, and political instability, we introduced the Political Terror Scale [PTS; (35)], an 5-level score developed by the American non-governmental organization (NGO) Freedom House in the early 1980s. This score uses data provided by Amnesty International and the U.S. Department of State. Countries with a PTS score equal to 1 are legally and politically stable, whereas countries with PTS scores equal to or greater than 4 are notably characterized by extensive human rights violations and increasing levels of politically and ideologically motivated violence.

RESULTS
We investigated 38 eligible original studies (Table 1) reporting data from a total population of 39,158 adult IDPs and refugees.

Origin of Studies
Conflict-affected regions and host countries of displaced populations were unevenly represented: six original studies were conducted in the Middle East (Iran, Syria, Jordan, Lebanon, and Turkey) (44, 59, 67, 68, 70, 71), two were conducted in Latin America (Mexico, Colombia) (10, 55), six in Central and Eastern Europe (Croatia and Georgia) (38, 40, 61–63, 66), eight in Asia (Thailand, Myanmar, Sri Lanka, Nepal, China, and Cambodia) (36, 37, 41, 43, 45, 48, 54, 60), and 16 in Africa (Sudan, Uganda, Liberia, Nigeria, Kenya, The Gambia, Senegal, and Ethiopia) (11, 39, 42, 46, 47, 49–53, 56–58, 64, 65, 69). The majority of studies were conducted in countries with a PTS score of 4 (n = 13) or 5 (n = 18).

Demographics
With regard to demographic factors, 26 studies (10, 11, 36, 38–41, 45, 47, 50, 51, 54–56, 58–66, 69–71) reported on samples that consisted of a majority (50–75%) of internally displaced or refugee women. Mean age ranged between 30 and 40 years in 21 studies (10, 11, 36, 38, 39, 42, 43, 46, 47, 49–52, 58, 60, 63–65, 68, 69, 71). In terms of status of displacement, our systematic research yielded quasi-similar results: IDPs and refugees were the primary population of interest in 16 countries (11, 48–51, 53–56, 58, 60–65) and 16 studies (10, 11, 36, 38, 40, 42, 43, 45–47, 52, 57, 59, 66, 67, 69), respectively. The mean duration of displacement ranged from 6 months to 18 years (10, 36, 38, 42, 43, 45, 47–59). Although the strict UNHCR concept of protracted situation was...

(Continued)
not used as an inclusion criterion, nine studies selected in this review described durations of displacement > 5 years (10, 36, 43–45, 51, 56–58). Levels of traumatic exposure among forcibly displaced populations were significant and reached an average number of seven experienced and/or witnessed traumatic events per participant (10, 11, 37, 38, 40, 42, 48, 50–52, 54, 56, 61, 65, 69). These events included different forms of psychological stressors: witnessing the murder of a family member, friend, or stranger; being close to death, tortured, beaten, or arbitrarily imprisoned; being violently separated from family or isolated from other social groups, raped or sexually abused, and forced to accept ideas against one's will (11, 46).

**Assessment Methods**

Most eligible studies included in our review used well-established mental health questionnaires administered by trained lay interviewers or medical practitioners. Questionnaires were systematically assessed for cultural validity, translated, and administered in the participants' native language. The HTQ (33) was the preferred assessment method and was used in almost 50% of the studies looking into the prevalence of PTSD [15 of 33 studies; (10, 11, 36–42, 48, 51, 54, 65, 66)]. Anxiety disorders and depression were mostly assessed through the HSCL-25 [17 of 31 studies; (34)] (10, 11, 36–39, 41, 42, 45, 48, 50–52, 54, 59, 66). With regard to PTSD, depression, and anxiety disorders, several authors also reported the Composite International Diagnostic Interview [CIDI; (72)] as a cross-culturally validated assessment method consisting of structured clinical interviews based on DSM-IV and ICD-10 diagnostic criteria (43, 48, 52, 60, 65). In two distinct studies, clinicians administered specific CIDI modules in order to validate the diagnoses mentioned above (48, 52). Common mental disorders were assessed either by means of the Mini-International Neuropsychiatric Interview (MINI) (57, 58, 67, 70, 71), a structured clinical diagnostic interview according to the DSM-IV and ICD-10, or the CIDI (43, 60). One group of experts based their evaluation of axis-I mental disorders on the Structured Clinical Interview for DSM [SCID-I; (64)]; administered by trained psychiatrists. Definitive clinical diagnoses were based on validated diagnostic modules such as DSM-III-R, DSM-IV, DSM-IV-TR, and ICD-10 (40, 46, 68). Seven studies measured alcohol related problems and reported different screening methods: the CAGE questionnaire (58), the AUDIT questionnaire (40)—a more detailed set of questions developed by the World Health Organization (WHO) to detect hazardous drinking—MINI standard interviews (56, 62), structured psychiatric interviews focused on alcohol abuse based on the DSM-III or DSM-IV (50, 57, 71), and the SCID-I (40).

**Prevalence of Psychiatric Disorders: PTSD, Depression, and Anxiety Disorders**

PTSD, depression, and anxiety disorders were the most common psychiatric illnesses investigated. However, prevalence rates of PTSD were disproportionately represented in 30 studies and consistently high: data varied between 2.2 and 88.3% (64). We found depression and anxiety disorders to be the second and third most commonly reported mental disorders among IDPs and refugees: specific estimates varied from 5.1 to 81% for
depression (10, 11, 36–43, 45–48, 50–55, 57, 58, 60–65, 68, 71) and from 1 to 90% for anxiety disorders (10, 11, 36–39, 41, 42, 44–46, 48–52, 54, 55, 57–67, 69, 70). Estimates of more precise diagnoses of anxiety disorders were compatible with the high prevalence of unspecified anxiety among displaced populations. One study showed that generalized anxiety disorder, social phobia, and obsessive-compulsive disorder affected 23, 14, and 5%, respectively, of a sample of 1,876 long-term IDPs in Central Sudan (58).

Prevalence of Psychiatric Disorders: Common Mental Disorders

Fifteen studies looked beyond the general concepts of trauma, PTSD, anxiety, and depression in settings of conflict-related forced displacement (40, 43, 44, 46, 49, 56–64, 67, 69, 71). These studies considered additional conditions such as substance abuse, psychosis, suicidality, personality disorders, and other forms of mood and anxiety disorders.

Alcohol use disorders were the most common type of substance abuse reported and were particularly prevalent among displaced men (2–60%) (40, 56–58, 62, 64, 65). A Croatian study described rates of non-comorbid alcohol dependence as high as 60.5% (40). Conversely, although drug abuse reached 20% in one recent survey assessing common mental disorders (CMD) in a mixed population of IDPs and refugees in South-western Nigeria (57), drug abuse generally did not exceed 2% (58, 60, 70).

Psychotic disorders were explored in two different samples of African IDPs and refugees and one selected group of refugees in Lebanon: data were heterogeneous and prevalence ranged between 1 and 12% (46, 58, 67). Psychotic symptoms such as visual or auditory hallucinations, however, presented in one African study were as high as 13 and 21%, respectively (57).

We identified four studies completed in Sudan, Southwestern Nigeria, and Lebanon that investigated suicidality, representing a population of 4,447 adult IDPs and refugees (49, 57, 58, 67). In one recent study conducted in a refugee camp in Lebanon by the French NGO Médecins sans Frontières, current rates of suicidality reached 12% (67). Similar results were observed in a Nigerian refugee camp (57). A survey examining the health status of internally displaced adult females in Darfur reported a prevalence rate of 2% for more specific suicidal behaviors, namely attempted or committed suicide (49).

Prevalence of pain disorders was 29% in a group of 392 non-tortured Bhutanese refugees in Nepal (43). Similarly, somatoform disorders were examined in only one survey, conducted in Sri Lanka, and found to affect 14% of 450 IDPs (60).

DISCUSSION

In recent years, there has been a growing interest in research activities related to the psychiatric health sequelae of armed conflicts. The high number of people affected globally by organized violence and the low level of available knowledge justify the growth in both quality and quantity of these activities. This systematic review examined for the first time the prevalence of common and uncommon psychiatric disorders among IDPs and refugees displaced as a consequence of armed conflicts in LMICs. The results suggest that PTSD, depression and anxiety disorder are highly prevalent after displacement and armed conflicts. This association can be partially accounted for by distinct psychosocial vulnerabilities of IDP and refugee populations.

This review highlights a lack of studies assessing the prevalence of mental health disorders among forcibly displaced populations in conflict-affected middle-eastern countries as only six studies originated from these regions. This result is particularly striking in view of the ever-changing and ever-increasing figures of worldwide forced migration. For example, according to a 2017 UNHCR report (60), countries such as Turkey, Pakistan, Lebanon, or the Islamic Republic of Iran hosted more than 28% of the world's refugees, people who had been affected from the ongoing conflicts in the Syrian Arab Republic or Afghanistan.

The detailed analysis of the studies included in this review showed a high variability in the duration of displacements between studies. However, we observed that the UNHCR definition of protracted situation was never used as a strict methodological consideration. Rates of trauma exposure were found to be not only high in terms of prevalence but also in terms of recurrence and intensity: all participants included in the reviewed studies had experienced or witnessed at least one serious traumatic event. Thirty-one studies were conducted in populations displaced from countries with a PTS score of four or five. Although prevalence of disorders reported across these countries were heterogeneous, the point estimates for those displaced from countries with a PTS score of less than three were on average lower than those in the highest two PTS quintiles. Understanding how unstable political situations with forced displacement relate to heightened rates of CMDs could inform the development of targeted interventions. Women tended to be over-represented in the studies included in this review, irrespective of their displacement status. This is in line with other literature in refugee and IDP populations (73). The traumas faced after displacement differ between men and women, and the effects of these traumas may manifest different (74). Additionally, this may have caused variance in the reported prevalence's of common psychiatric disorders, which have been shown to differ between men and women (e.g., substance-abuse disorders and depression) (75).

Our findings confirm a long-standing inclination of mental health research toward PTSD, depression, and anxiety disorders in settings of complex emergencies. Public mental health research conducted over the past 20 years has largely focused on the immediate psychological aftermaths of armed conflicts in light of the well-described associations between these psychiatric disorders, displacement, and generalized forms of violence. Demographic and socio-economic characteristics of displaced populations are known to be potent moderators of mental health: migration, especially internal displacement, protracted conflict situations, and economic instability are strongly associated with poor mental health outcomes (3).

We point out a substantial lack of data concerning the general mental health conditions of forcibly displaced populations.
in LMICs, which might be caused by different mechanisms (28): (1) stigma of mental disorders in developing countries, (2) disproportionate under-representation of several conflict-affected regions in the literature—such as Latin America, Central and Eastern Africa, Central Asia—(3) cultural or political barriers to assessment and implementation of mental health programs and policies such as insufficient funding of mental health research, (4) over-centralization of mental health resources, (5) severe shortage of adequately trained mental health staff, and, finally, (6) weak public health leadership in the field of mental health. The very few estimates about substance abuse, other mood and anxiety disorders, psychosis, or suicidality are higher than figures from the general population studies conducted in LMICs (13, 14, 76–84).

Lastly, there is a relative consensus on how to assess common mental disorders among IDPs and refugees. Structured questionnaires such as the HSCL-25, HTQ, PCL, and CIDI are largely favored for the evaluation of PTSD, depression, and anxiety disorders; they are also systematically examined for cultural validity, translated into the participants’ native language, and administered by trained lay people, mental health specialists or medical practitioners. Conversely, other forms of mental disturbances such as psychosis or suicidality are assessed through MINI or SCID interviews with the help of the DSM or ICD for diagnosis validation.

LIMITATIONS

This review has a number of limitations and should therefore be interpreted cautiously. Despite our systematic search strategy, it is likely that certain unpublished or non-indexed studies have not been included. We did not establish direct contacts with authors in order to identify additional studies. Furthermore, the generalizability of our results to the entire IDP or refugee population is limited. Most research groups have favored the cross-sectional study that has been repeatedly criticized for its limitations in terms of selection bias and causality analysis (85–87). The proportion of psychiatric cases pre-existing the conflict and directly caused or at least influenced by armed conflicts and subsequent displacements remains unclear due to a lack of mental health programs in LMICs.

The presented results were extracted from studies conducted in several regions that differ greatly in terms of population characteristics, culture, social traditions, religion, language, and even types of conflict or duration of displacement. No meta-analysis has been undertaken, therefore, inter-study variability and publication bias have not been examined, and heterogeneity has not been significantly reduced. Moreover, the cross-cultural aspect of a majority of studies may have influenced the final results (88).

The HSCL-25 and HTQ have been extensively used to assess depression, anxiety disorders, and PTSD among IDP sub-populations and refugees, but not validated for general populations in LMICs (89). Many validation studies have been conducted in novel contexts for these scales and others, but it is imperative that cultural adaptations be completed prior to their use in novel contexts (33, 90). In addition, both the HSCL-25 and the HTQ only report on symptoms. Therefore, it remains unclear to what extent these symptoms would correlate with formal clinical diagnoses based on the DSM or ICD.

Finally, some of studies did not specify whether any cultural adaptation was undertaken to formulate diagnostic criteria. Psychiatric presentation and diagnosis (including the criteria outlined in the DSM and ICD), are known to exhibit cross-cultural differences (91). Due to the recent refugee and humanitarian crises, psychometric measures and clinical interviews used to ascertain the presence of CMDs (i.e., depression, anxiety, and PTSD) in refugee populations have been widely studied and validated (92). In relation to the severe and uncommon disorders reported in this study, there is a paucity of research in the refugee context. As such, it is possible that authors used culturally unadapted methods to determine diagnosis and that estimated prevalence rates may not be representative of the true values in the populations studied.

PRACTICAL IMPLICATIONS AND CONCLUSION

Wars and other forms of organized violence generally draw the attention of policymakers, mass media, and non-governmental organizations. Mental health and public health experts tend to consider this selective and often temporary attention as an opportunity to raise awareness about the psychological consequences of armed conflicts, namely PTSD, to warn about the disastrous mental health situation in low- and middle-income countries. With the numbers of displaced individuals reaching unprecedented levels, a more global mental health approach is necessary to effectively support affected nations. In places where violence is seen as a necessary factor in achieving peace, ongoing armed conflict, and displacement will likely contribute to continued psychological impairment and suffering among those affected (50). Allowing for a better understanding of the effects that the aftermath of war have on the psychological well-being will allow for interventions not only targeting mental illness but also attitudes toward reconciliation and justice and reduction of future violence (93).

In sum, this systematic review indicates that the heterogeneity in prevalence rates is caused by methodological differences between studies and differences between conflict-affected IDP and refugee populations. We recommend that future public mental health research goes beyond the assessment of PTSD, depression, and anxiety disorders and consider a broader inclusive definition of the psychological consequences of armed conflict as additional key concept. In addition to that questionnaires assessing more severe disorders (e.g., psychotic disorders) which are often ignored need to be developed and validated for use in LMICs.
Ambitious and locally coordinated assessment programs of mental health should be implemented as well as non-centralized mental health policies and their systematic qualitative evaluations (94). Lastly, the on-going crises indicate that there is an urgent need for scalable interventions that are appropriate for war-torn contexts in which resources are limited. The World Health Organization is currently spearheading this with the so-called low-intensity intervention Problem Management Plus [PM+; (95)] being the most evidence-based release to date (96, 97). On-going research is aiming to increase the scope of this intervention to allow for group-based and application-based administration. However, the most critical challenge will be to translate these promising intervention programs into sustainable public mental health policies in countries so deeply weakened by protracted conflicts, destruction of fragile pre-existing health care structures, and political instability. Finally, it is unfortunately common that refugees and IDPs are not being treated fairly wherever they end up seeking protection and support, and are subjected to ongoing humiliating, traumatizing, or otherwise damaging circumstances. From a societal and ethical viewpoint, changing these circumstances may even constitute a higher priority than diagnosing and treating trauma-related mental illness.

**AUTHOR CONTRIBUTIONS**

All authors contributed to the study conception and design. AA and NM conducted literature search and data extraction. NM and AA performed data analyses and drafted the manuscript. All authors contributed to and approved the final version of the manuscript.

**ACKNOWLEDGMENTS**

We would like to acknowledge Laurent Levy's help in preliminary screening of the literature and data extraction.
