Background: Baicalein has a significant anti-cancerous function in the treatment of cervical cancer (CC). Its functional mechanism regarding circular RNA (circRNA) hippocampus abundant transcript 1 (circHIA1) and microRNA-19a-3p (miR-19a-3p) was explored in this research.

Methods: CC cell viability and colony formation were determined using Cell Counting Kit-8 (CCK-8) and colony formation assay. Cell cycle progression and apoptosis were analyzed via flow cytometry. Protein markers of cell cycle, apoptosis and protein kinase B/mammalian target of rapamycin (AKT/mTOR) pathway were detected by Western blot. circHIA1 and miR-19a-3p levels were assayed through the quantitative real-time polymerase chain reaction (qRT-PCR). The interaction between circHIA1 and miR-19a-3p was validated by dual-luciferase reporter and RNA pull-down assays. In vivo experiment was performed by xenograft model.

Results: CC cell growth and cell cycle progression were repressed while apoptosis was enhanced by baicalein. MiR-19a-3p was downregulated in baicalein-treated CC cells and miR-19a-3p overexpression lightened the baicalein-induced CC progression inhibition. Moreover, circHIA1 was found to be a sponge of miR-19a-3p in CC cells. Baicalein-induced cell growth inhibition, cell cycle arrest and apoptosis promotion were neutralized by knockdown of circHIA1 via targeting miR-19a-3p. Baicalein acted on the circHIA1/miR-19a-3p to inactivate AKT/mTOR pathway. Baicalein also reduced CC tumor growth in vivo via regulating the levels of circHIA1 and miR-19a-3p.

Conclusion: These findings demonstrated that the inhibitory function of baicalein in CC progression was dependent on the repression of AKT/mTOR pathway by upregulating circHIA1 to sponge miR-19a-3p, showing a specific mechanism for baicalein in CC.

Keywords: baicalein, cervical cancer, circHIA1, miR-19a-3p, AKT/mTOR

Introduction

Cervical cancer (CC) is one of the most common malignancies in women and high-risk subtypes of human papilloma virus (HPV) is the leading cause.1 Conservative, fertility-preserving surgical operation remains the primary therapeutic option for early-stage CC patients, with the concurrent chemoradiotherapy and brachytherapy.2 However, the overall prognosis for patients with metastatic and recurrent CC is still poor.3 To explore more therapeutic regimens is necessary for the management of CC.
Baicalein is a flavonoid coming from the root of *Scutellaria baicalensis* that is a traditional Chinese herb.4 Baicalein has important pharmacological activities, such as anti-tumorous, anti-inflammatory, antiviral and antioxidative effects.5 Issued reports have found the inhibitory effects of baicalein on various human cancers, including non-small cell lung cancer,6 hepatocellular carcinoma,7 breast cancer,8 thyroid cancer,9 and so on. Regarding the functional mechanisms of anticancer baicalein, it is mainly because of its inhibition on cell cycle progression by regulating cyclins, promotion of apoptosis by activating caspase-3/9, and the activity repression of mitogen-activated protein kinase (MAPK), protein kinase B (AKT) or mammalian target of rapamycin (mTOR).5 In the CC research, baicalein has been shown to suppress cell proliferation by Notch 1/Hes signaling pathway10 or Wnt signaling pathway,11 and induce cell apoptosis by affecting the activity of nuclear factor (NF)-κB.12 The association of baicalein and AKT/mTOR pathway in CC has not been researched.

Increasing studies have indicated that the baicalein regulated the expression of microRNAs (miRNAs) in cancers. For example, baicalein retarded the progression of osteosarcoma via upregulating miR-183,13 bladder cancer by down-regulating miR-106,14 and hepatocellular carcinoma through miR-3127 inhibition.15 MicroRNA-19a (miR-19a) served as a pro-cancer factor in CC.16,17 However, the relation between baicalein and miR-19a-3p is unreported. MiRNAs can be used as the targets of circular RNAs (circRNAs) that are covalently closed loops, and circRNAs function as regulatory molecules by sponging miRNAs in cancer progression.18 CircRNA hippocampus Abundant Transcript 1 (circHIA1) restrained hepatocellular carcinoma cell growth by acting as a miR-3171 sponge19 and hampered gastric cancer progression via absorbing miR-21.20 This study will also address whether circHIA1 can be a sponge for miR-19a-3p in CC.

Herein, the function of baicalein in CC cells and the potential regulation of baicalein on miR-19a-3p, circHIA1 and AKT/mTOR pathway are investigated. The target relation between circHIA1 and miR-19a-3p is confirmed.

Materials and Methods

Human Samples

Thirty-six CC patients have signed the written informed consent forms before surgical resection at Suizhou Hospital, Hubei University of Medicine. Thirty-six paired CC and non-tumorous tissue samples were collected into the sterile centrifugal tubes (Axygen, Santa Clara, CA, USA) during the surgery, then saved at −80°C instantly. All operations and use of these human samples were in accordance with the Declaration of Helsinki involving in the human subjects, based on getting authorization from the Ethics Committee of Suizhou Hospital, Hubei University of Medicine.

Cell Lines and Baicalein Stimulation

Human CC cell lines (HeLa and SiHa) and normal cervical epithelial cell line End1/E6E7 were bought from American Type Culture Collection (ATCC, Manassas, VA, USA). Cell culture was performed in Dulbecco’s Modified Eagle’s Medium (DMEM; Gibco, Carlsbad, CA, USA) added with 10% (v/v) fetal bovine serum (FBS; Gibco) and 1% (v/v) penicillin & streptomycin solution (Gibco) in a 37°C incubator containing 5% CO₂. Baicalein (Sigma-Aldrich, St. Louis, MO, USA) was dissolved in dimethyl sulfoxide (DMSO; Invitrogen, Carlsbad, CA, USA) to reach the concentrations of 20 μg/mL and 40 μg/mL. HeLa and SiHa cells were treated with baicalein at 37°C for 24 h, and the DMSO treatment group (Baicalein 0 μg/mL) was used as the negative control. The baicalein concentration was used in a reasonable range referring to the previous studies.21,22

Cell Transfection

MiRNA mimics of miR-19a-3p (miR-19a-3p) and negative control (miR-NC), miRNA inhibitors of miR-19a-3p (anti-miR-19a-3p) and negative control (anti-miR-NC) were synthesized by GenePharma (Shanghai, China). Short hairpin RNA (shRNA) vector targeting circHIA1 (sh-circHIA1) and its negative control (sh-NC), pCE-RB-Mam-circHIA1 overexpression vector (circHIA1) and the control vector pCE-RB-Mam (vector) were purchased from RIBOBIO (Guangzhou, China). HeLa and SiHa cells were cultivated for 60% monolayer confluence, then cell transfection was conducted by Lipofectamine™ 3000 (Invitrogen).

Cell Counting Kit-8 (CCK-8) Assay

Viable cells were detected using Cell Counting Kit-8 (CCK-8; Dojindo Molecular Technologies, Kumamoto, Japan). Then, 2 × 10³ HeLa and SiHa cells were seeded into the 96-well plates overnight at 37°C. After baicalein treatment (24 h) and transfection (48 h), 10 μL CCK-8 solution was pipetted into each well of the 96-well plates to incubate for 3 h. Cell viability (%) was obtained after
the absorbance determination by the microplate reader (Bio-Rad, Hercules, CA, USA).

**Colony Formation Assay**

Colony formation ability was assessed using colony formation assay. 2 × 10^2 treated or transfected HeLa and SiHa cells were harvested, then transplanted into the 6-well plates for cell growth at 37°C. After 2 weeks, methanol (Sigma-Aldrich) was added into the wells for fixing these colonies and crystal violet (Sigma-Aldrich) was used to stain colonies. Then, the stained colonies were manually counted.

**Flow Cytometry**

Flow cytometry was applied for analyzing cell cycle and apoptosis. For cell cycle, HeLa and SiHa cells were stained by propidium iodide (PI) according to the Cell Cycle Assay Kit - PI/RNase Staining (Dojindo Molecular Technologies), followed by the detection of cell proportions at G0/G1, S and G2/M phases on the flow cytometer (BD Biosciences, San Diego, CA, USA). For cell apoptosis, HeLa and SiHa cells were stained by Annexin V-fluorescein isothiocyanate (FITC) and PI through Annexin V-FITC Apoptosis Detection Kit (Dojindo Molecular Technologies); then, the apoptotic cells (%) were discerned under the flow cytometer.

**Western Blot**

After cell harvest and tissue collection, total proteins were extracted via radioimmunoprecipitation assay (RIPA; Thermo Fisher Scientific, Waltham, MA, USA). Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) was performed to separate proteins from the loading products to the gels; then, proteins on the gels were transferred to the polyvinylidene difluoride (PVDF) membranes (Thermo Fisher Scientific). PVDF membranes were blocked in 5% skim milk (Invitrogen), followed by the incubation of primary antibodies against cyclin D1 (#2922, 1:1000), p21 (#2947, 1:1000), p27 (#3686, 1:1000), B-cell lymphoma-2 (Bcl-2; #4223, 1:1000), Bcl-2-associated X (Bax; #5023, 1:1000), phospho-AKT (p-AKT; #4060, 1:2000), AKT (#4691, 1:1000), phospho-mTOR (p-mTOR; #5536, 1:1000), mTOR (#2983, 1:1000) or internal control glyceraldehyde-phosphate dehydrogenase (GAPDH; #8884, 1:1000) at 4°C overnight. Enhanced chemiluminescence (ECL; Bio-Rad) was exploited for protein presentation after the membranes were incubated with a second antibody (#7074, 1:3000) for 1 h at room temperature. The protein bands were captured and analyzed by Image Lab software (Bio-Rad). The antibodies used in this study were purchased from Cell Signaling Technology (CST, Boston, MA, USA).

**The Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR)**

The expression levels of circHIA1 and miR-19a-3p were examined by qRT-PCR. Briefly, total RNA was isolated from tissues and cells using TRI Reagent (Sigma-Aldrich) and reversely transcribed to obtain the complementary DNA (cDNA) by ReadyScript cDNA Synthesis Mix (Sigma-Aldrich), followed by performing the qRT-PCR through SYBR® Green Quantitative RT-qPCR Kit (Sigma-Aldrich) and data analysis via the 2^−ΔΔCt method. The nucleotide sequences of primers were shown as follows: forward (F), 5'-GCAGTCCCTTGGCATTTCTTT3'- and reverse (R), 5'-CAA GGTTGGTGCTGTAATA3' for circHIA1; F, 5'-GGGG GGGGTGTGCAAATCT3'- and R, 5'-GTGCGTGTGCGTG AGTCCG3'- for miR-19a-3p; 5'-AAGGGATAGGTC GAGTCA-3' and R, 5'-GGGAAGATGTTGATGGAGTTT 3' for GAPDH; 5'-AGACCGCTGTTGTCGCG3'- and R, 5'- CATCCTCAAGCACCCTCC3' for U6. CircHIA1 and miR-19a-3p levels were respectively normalized by GAPDH and U6.

**Dual-Luciferase Reporter Assay**

CircBank was used for predicting the binding between circHIA1 and miR-19a-3p. The fragment of circHIA1 that contained the binding sites of miR-19a-3p was amplified and inserted into the pmiRGL (Promega, Madison, WI, USA). The formed wild-type (WT) luciferase plasmid was named as circHIA1-WT. After the binding sites of miR-19a-3p in circHIA1 sequence were mutated, the constructed mutant-type (MUT) plasmid was named as circHIA1-MUT. CircHIA1-WT or circHIA1-MUT and miR-19a-3p or miR-NC were co-transfected into HeLa and SiHa cells for 48 h, then the luciferase activity was determined applying with the Dual-Luciferase Reporter Assay System (Promega).

**RNA Pull-Down Assay**

Biotin-coupled miRNA mimics: Biotin-miR-19a-3p-WT, Biotin-miR-19a-3p-MUT and Biotin-miR-NC were bought from RIBOBIO. At 48 h after transfection of each mimic, HeLa and SiHa cell lysates were harvested and incubated in streptavidin magnetic beads (Thermo Fisher Scientific).
at 4°C overnight. After total RNA isolation from the magnetic beads, relative circH1AT1 expression was measured via qRT-PCR assay.

Animal Assay

This animal assay was ratified by the Animal Ethical Committee of Suizhou Hospital, Hubei University of Medicine. Female BALB/c nude mice (5-week-old, n=18) were purchased from Vital River Laboratory Animal Technology Co. Ltd (Beijing, China) and divided into three groups with six mice/group. Transfected (sh-NC, sh-circH1AT1) HeLa cells (3 × 10⁶) were subcutaneously injected into the flank of mice, then the mice were intraperitoneally treated with 100 μL DMSO (0.25%) in sh-NC group or 10 mg/kg baicalein in sh-NC and sh-circH1AT1 groups daily. Tumor volume was measured every 5 days using the equation: length × width² × 0.5. Tumor was dissected from mice at the 30th day post-injection, and total RNA or protein was extracted for associated expression analysis. The care and euthanasia for mice followed the Management and Use Guidelines of Laboratory Animals issued by the National Institutes of Health (NIH).

Statistical Analysis

Each experiment was independently performed for three times and data were shown as the mean ± standard deviation (SD). The linear association between circH1AT1 and miR-19a-3p was analyzed using Spearman correlation coefficient. Data analysis was administrated by SPSS 24.0 and statistical difference was compared via Student’s t-test or one-way analysis of variance (ANOVA) followed by Tukey’s test. P<0.05 was expressed as a significant difference.

Results

Baicalein Caused CC Cell Growth Suppression, Cell Cycle Arrest and Cell Apoptosis Promotion

The effects of baicalein on CC cellular behaviors were explored after treatment of different concentrations in HeLa and SiHa cells. The results of CCK-8 and colony formation assays suggested that cell viability (Figure 1A) and colony formation ability (Figure 1B–C) were repressed in baicalein 20 μg/mL and 40 μg/mL groups compared to 0 μg/mL group, in a dose-dependent way. The inhibition of cell transition from G0/G1 phase to S phase indicated that baicalein treatment resulted in cell cycle retardation of HeLa and SiHa cells (Figure 1D–F). In addition, cell apoptosis was found to be enhanced by baicalein through Annexin V-FITC/PI-flow cytometry (Figure 1G–H). Western blot was performed to measure the proteins associated with cell cycle (positive marker cyclinD1 and negative regulators p21/p27) and cell apoptosis (negative Bcl-2 and positive Bax). As the protein presentation in Figure 1I, baicalein stimulation decreased the levels of cyclinD1 and Bcl-2 but upregulated p21, p27 and Bax (Figure 1J–K). Taken together, baicalein inhibited cell growth, cell cycle progression and promoted apoptosis of CC cells.

Baicalein Downregulated the Expression of miR-19a-3p in CC Cells

In comparison to the 0 μg/mL group, miR-19a-3p expression was significantly declined by baicalein treatment of 20 μg/mL and 40 μg/mL groups in HeLa and SiHa cells (Figure 2A). The qRT-PCR data revealed that miR-19a-3p level was much higher in HeLa or SiHa cells (Figure 2B) and CC tissue samples (Figure 2C) than that in normal End1/E6E7 cell line and normal tissue samples. The expression of miR-19a-3p was inhibited by baicalein in CC cells.

Baicalein-Induced Inhibition of CC Progression Was Attenuated by miR-19a-3p Overexpression

Due to the downregulation of miR-19a-3p by baicalein, miR-19a-3p mimic was used for miR-19a-3p overexpression to study the influence of miR-19a-3p on baicalein in CC cells. As shown in Figure 3A, the expression of miR-19a-3p was increased by more than 10-fold changes in miR-19a-3p-transfected HeLa and SiHa cells relative to miR-NC transfection. After 40 μg/mL baicalein treatment, miR-19a-3p or miR-NC was transfected into HeLa and SiHa cells and DMSO+miR-NC acted as the negative control. Through a series of cellular experiments, we found that baicalein-induced repressive effects on cell viability (Figure 3B), colony formation (Figure 3C–D) and cell cycle progression (Figure 3E–F), but the accelerative effect on cell apoptosis (Figure 3G–H) was assuaged following the overexpression of miR-19a-3p. Consistently, the transfection of miR-19a-3p also rescued all these influences of baicalein on cyclinD1, p21, p27, Bcl-2 and Bax protein levels in Western blot assay (Figure 3I–K). These results implied...
that the inhibition of baicalein in CC progression was associated with miR-19a-3p downregulation.

CircHIA T1 Was a Natural Sponge for miR-19a-3p in CC Cells

Bioinformatic analysis of circBank showed that circHIA T1 (hsa_circHIA T1_007) contained the complementary binding sites (UUGCAC) for miR-19a-3p (AACCUG) (Figure 4A). After these binding sites were mutated as AACCUG in circHIA T1 sequence, the dual-luciferase reporter assay was performed. The results manifested that circHIA T1-WT and miR-19a-3p co-transfection signally suppressed the relative luciferase activity but circHIA T1-MUT and miR-19a-3p co-transfection made no difference in the luciferase activity, in contrast with their co-transfection with miR-NC (Figure 4B–C). Pull-down assay also exhibited that the capture of circHIA T1 by Biotin-miR-19a-3p-WT, not Biotin-miR-19a-3p-MUT and Biotin-miR-NC (Figure 4D). The qRT-PCR affirmed that circHIA T1 expression was interfered by sh-circHIA T1 and elevated by circHIA T1 transfection.
respectively, compared to sh-NC or vector group (Figure 4E). Negatively, miR-19a-3p level was shown to be upregulated by knockdown of circHIA1 while circHIA1 overexpression caused the downregulation of miR-19a-3p in HeLa and SiHa cells (Figure 4F). Contrary to miR-19a-3p, circHIA1 level was promoted after the treatment of...
baicalein (20 μg/mL and 40 μg/mL) by comparison to baicalein 0 μg/mL (Figure 4G). Relative to the control End1/E6E7 cells and normal tissues, the expression of circHIA1 was obviously lower in CC cells (Figure 4H) and tissues (Figure 4I). The relation between circHIA1 and miR-19a-3p was analyzed to be negative \( r=-0.57, p<0.05 \) in CC tissue samples (Figure 4J). The above data identified circHIA1 as a sponge of miR-19a-3p in CC cells.

**Knockdown of circHIA1 Alleviated the Inhibition of Baicalein on CC Progression via Upregulating miR-19a-3p**

Given that circHIA1 targeted miR-19a-3p, the potential regulation of circHIA1 on baicalein was further investigated. MiR-19a-3p expression was evidently inhibited by anti-miR-19a-3p transfection in contrast with anti-miR-NC transfection (Figure 5A). 40 μg/mL baicalein-treated HeLa and SiHa cells were transfected with sh-NC+anti-miR-NC, sh-circHIA1+anti-miR-NC or sh-circHIA1+anti-miR-19a-3p, then the functional assays were carried out using DMSO+sh-NC +anti-miR-NC as the control group. The introduction of sh-circHIA1 abrogated the baicalein-mediated cell viability (Figure 5B) and colony formation (Figure 5C and D) repression, cell cycle blockage (Figure 5E and F) and the increase of apoptotic rate (Figure 5G–H), whereas these alleviative effects were eliminated by miR-19a-3p inhibitor. Similarly, miR-19a-3p inhibition counterbalanced the circHIA1-regulated reversal on the protein expression downregulation of cyclinD1 and Bcl-2, as well as upregulation of p21, p27, and Bax caused by baicalein (Figure 5I–K). Briefly, knockdown

---

**Figure 4** CircHIA1 was a natural sponge for miR-19a-3p in CC cells. (A) The analysis of binding sites between circHIA1 and miR-19a-3p was carried out using circBank. (B–D) Dual-luciferase reporter assay (B–C) and RNA pull-down assay (D) were used to explore whether circHIA1 could combine with miR-19a-3p. (E–F) CircHIA1 (E) and miR-19a-3p (F) expression analysis was administrated employing qRT-PCR in HeLa and SiHa cells transfected with sh-NC, sh-circHIA1, vector or circHIA1. (G–I) The qRT-PCR was applied for detecting circHIA1 expression in baicalein-treated HeLa and SiHa cells (G), End1/E6E7 and HeLa/SiHa cells (H) and normal/CC tissues (I). (J) Spearman correlation coefficient was exploited for analyzing the relationship between circHIA1 and miR-19a-3p in CC tissues. Three technical replications \((n=3)\) were performed in each experiment. \(*p<0.05\).
of circHIA1 upregulated miR-19a-3p to abate the baicalein-induced effects on cell growth, cell cycle and apoptosis.

**Baicalein Blocked the AKT/mTOR Pathway by Upregulating circHIA1 to Inhibit miR-19a-3p**

To analyze whether baicalein could affect AKT/mTOR pathway via regulating circHIA1 and miR-19a-3p, we detected the protein expression of p-AKT/AKT and p-mTOR/mTOR in HeLa and SiHa cells. As the Western blot results illustrated in Figure 6A–B, the protein levels of p-AKT/AKT and p-mTOR/mTOR were significantly downregulated in Baicalein +sh-NC+anti-miR-NC group than these in DMSO+sh-NC+anti-miR-NC group while the inhibition of baicalein on AKT/mTOR pathway was assuaged by the transfection of sh-circHIA1, and it was interesting that miR-19a-3p inhibitor subsequently eliminated the promotion of AKT/mTOR pathway by sh-circ-HIA1. Collectively, baicalein inhibited the AKT/mTOR signal pathway through the regulation of circHIA1/miR-19a-3p axis.

**CC Tumor Growth Was Suppressed by Baicalein via the circHIA1/miR-19a-3p Axis in vivo**

After mice were injected with transfected cells and DMSO or baicalein for 30 days, the measurement of tumor volume (Figure 7A) and weight (Figure 7B–C) indicated that baicalein treatment reduced CC growth while sh-circHIA1 weakened this inhibition. The qRT-PCR analysis in tumor tissues
exhibited that baicalein-induced circHIA1 upregulation (Figure 7D) and miR-19a-3p downregulation (Figure 7E) were retained in Baicalein+sh-circHIA1 group. Also, the protein level of cyclinD1 and Bcl-2 were decreased but p21, p27 and Bax were facilitated in the Baicalein+sh-NC group relative to the DMSO+sh-NC group, which was then abolished in the Baicalein+sh-circHIA1 group (Figure 7F–G). Therefore, baicalein restrained CC tumor growth in vivo via increasing circHIA1 to inhibit miR-19a-3p.

**Discussion**

It is unclear whether the function of baicalein on the development of CC is achieved by regulating some circRNAs and miRNAs. Our exploration in this study discovered that baicalein worked as a tumor inhibitor in CC through upregulating circHIA1 to sequester the expression of miR-19a-3p to inhibit AKT/mTOR pathway, proving that the regulation of baicalein was associated with the circHIA1/miR-19a-3p/AKT/mTOR axis in CC.

Bacicalein is known as an effective inhibitor in the tumor progression. For instance, Chen et al reported that baicalein blocked cell proliferative activity and cell cycle in colorectal cancer; Yang et al declared that cell viability in bladder cancer was impeded while apoptosis was induced by baicalein; Ma et al found that baicalein treatment resulted in cell proliferation inhibition and cell cycle arrest of prostate...
In this chapter, cellular experiments have shown that CC cell viability, colony formation, cell cycle progression were all reduced but apoptotic cells were increased by baicalein. CyclinD1 is a key protein in the process of cell cycle progression. In addition, p21 and p27 are correlated to Cdk/cyclin complexes and inhibit the activities of kinases at the G1/S and G2/M checkpoints. Our Western blot results suggested that baicalein led to the downregulation of cyclinD1 and upregulation of p21/p27. Treatment of baicalein also inhibited the protein expression of anti-apoptotic Bcl-2 and enhanced the level of pro-apoptotic Bax in CC cells. Judging from these experimental data, baicalein was affirmed to play an inhibitory role in the malignant progression of CC.

MiRNAs are a class of commonly researched regulatory RNAs in cancer research, and various miRNAs have been identified as employable biomarkers for diagnosis, treatment and prognosis in CC. Juan et al have shown that miR-489 served for an anti-proliferative and pro-apoptotic maker in CC cells, and miR-148a was used as a novel target to suppress the progression of CC. Interestingly, we found that miR-19a-3p was highly expressed in CC tissues and cells but its expression was reduced after baicalein treatment in CC cells, which demonstrated that the biological function of baicalein in CC might be related to the downregulation of miR-19a-3p. Our reverted assays subsequently exhibited that the overexpression of miR-19a-3p recovered the regulation of baicalein in CC cells, validating that baicalein functioned in CC cells via the expression inhibition of miR-19a-3p. Usually, circRNAs are used as another specific regulators in the progression of human cancers via targeting miRNAs. CircRNA-000911 was reported as an anti-oncogenic factor in breast cancer through the sponge effect on miR-449a and circRNA-100338 facilitated tumor progression in hepatitis B-related hepatocellular carcinoma by sequestering miR-141-3p. Through the online target binding prediction, miR-19a-3p might be a target of circHIA1. Dual-luciferase reporter and pull-down assays further verified that circHIA1 directly interacted with miR-19a-3p. Moreover, circHIA1 was found to negatively affect the miR-19a-3p level as a miRNA sponge. The current studies manifested that circHIA1 was a repressive regulator in some cancers (clear cell renal cell carcinoma, hepatocellular carcinoma and gastric cancer). CircHIA1 was also differentially downregulated in CC tissues and cells, but baicalein promoted its expression. The influences of baicalein on CC cells were offset after knockdown of circHIA1, suggesting that the upregulation of circHIA1 was responsible for baicalein as an inhibitor in CC progression. Furthermore, the regulation of circHIA1 in baicalein-induced CC cells was achieved by the negative effect on miR-19a-3p. In vivo assay, baicalein also reduced tumorigenesis of CC by regulating circHIA1 and miR-19a-3p.

Guo et al have shown that baicalein suppressed the AKT/mTOR pathway to reduce cell proliferation and metastasis in prostate cancer. Li et al also found the inhibition of baicalein on gastric cancer cell growth via decreasing the activities of AKT/mTOR signaling. The same signal blockage of AKT/mTOR pathway was caused by baicalein in anaplastic thyroid cancer cells. Herein, the levels of p-AKT/AKT and p-mTOR/mTOR were decreased by baicalein treatment in CC cells, whereas the circHIA1/miR-19a-3p axis was further exhibited to be responsible for the signal inhibition of AKT/mTOR by baicalein. Thus, baicalein could regulate AKT/mTOR pathway via targeting the circHIA1/miR-19a-3p axis.

The current research is always interested in targeting cancer therapy through the inhibition of mTOR. Rapamycin is a macrolide antibiotic with antiproliferative property as an

![Diagram](https://www.dovepress.com/)

Figure 8 Baicalein inactivated the AKT/mTOR pathway to inhibit the carcinogenesis of CC by upregulating circHIA1 to sponge miR-19a-3p.
mTOR inhibitor, and it cannot directly reduce the kinase activity of mTOR instead of the conformational changes in mTOR. However, the dose of rapamycin is difficult to be controlled. The low dose of rapamycin only induces the partial dissociation of mTOR and Raptor (involving in the mTORC1 substrate recognition), while high dose of rapamycin causes the complete dissociation to trigger the off-target effect. In our study, we found that baicalein exerted the anticancer function in CC cells both at 20 μg/mL and 40 μg/mL. The issued report also revealed that baicalein inhibited proliferation of HeLa cells in a dose-dependent manner (from 25 μg/mL to 200 μg/mL). In comparison to rapamycin, baicalein could be a better drug for preventing mTOR signaling in CC progression. A previous study has indicated that the inhibition of mTOR regulated the Gln deprivation to affect the glutamine (Gln)-mediated G1 checkpoint in cell cycle arrest. There are a series of metabolic checkpoints in the late G1 phase that prevent cells’ entry into S-phase, and mTOR inhibition arrests cells in the late G1 because it may limit the nutrient sufficiency in replicating the genome. Due to the repression of baicalein on AKT/mTOR pathway, it is likely that baicalein inhibits the necessary nutrients to block the metabolic checkpoints by inactivating the AKT/mTOR pathway. This matter remains to be studied in the future.

In conclusion, this research unraveled that baicalein targeted the circHIA1/miR-19a-3p axis to inactivate the AKT/mTOR pathway to inhibit the onco genesis in CC (Figure 8). The circHIA1/miR-19a-3p/AKT/mTOR signal network will contribute to understanding the functional mechanism of baicalein in CC progression. CircHIA1 and miR-19a-3p can be used as available targets in the baicalein-mediated treatment of CC.

**Highlights**

1. Baicalein downregulates miR-19a-3p expression but upregulates circHIA1 level in cervical cancer cells.
2. CircHIA1 is a sponge for miR-19a-3p.
3. Baicalein inhibits AKT/mTOR pathway via regulating circHIA1 and miR-19a-3p.
4. Baicalein impedes cervical cancer cell progression via the circHIA1/miR-19a-3p axis.

**Data Sharing Statement**

The analyzed data sets generated during the present study are available from the corresponding author on reasonable request.

**Ethics Approval and Consent to Participate**

The present study was approved by the ethical review committee of Suizhou Hospital, Hubei University of Medicine. Written informed consent was obtained from all enrolled patients.

**Consent for Publication**

Patients agree to participate in this work.

**Disclosure**

The authors declare that they have no competing interests in this work.
