ABSTRACT

We study 3d \( \mathcal{N} = 2 \) Chern-Simons (CS) quiver theories on \( S^3 \) and \( \Sigma_g \times S^1 \). Using localization results, we examine their partition functions in the large rank limit and requiring the resulting matrix models to be local, find quiver theories that have quivers in one-to-one correspondence with the \( \hat{A}\hat{D}\hat{E} \) Dynkin diagrams. We compute explicitly the partition function on \( S^3 \) for \( \hat{D} \) quivers and that on \( \Sigma_g \times S^1 \) for \( \hat{A}\hat{D} \) quivers, which lead to certain predictions for their holographic duals.

1 Introduction and Outline

Supersymmetric localization has made a whole host of theories accessible to non-perturbative analysis. It provides a powerful framework to construct and compute quantities along the RG flow non-perturbatively. One of them is the exact partition function $Z$ for supersymmetric gauge theories put on various curved manifolds in different dimensions (see [1] and references therein). This has led to a deeper understanding, checks and / or discovery of various dualities among field theories, even across dimensions. Since one gets access to exact results, one can test AdS/CFT correspondence in the regime relating weak gravity results (may or may not have been obtained via localization) to strong coupling results in the field theory (highly likely to have been obtained via localization). We will focus here on this latter possibility with the study of supersymmetric quiver gauge theories in three-dimensions, i.e., an example of AdS$_4$/CFT$_3$.

Free Energy. Localization was successfully applied to compute the partition function of 3d Chern-Simons-matter (CSm) theories placed on 3-sphere $S^3$ in [2–4]. The first explicit construction of a 3d $\mathcal{N} = 6$ gauge theory with M-theory dual was by ABJM [5]. It involved two $U(N)$ gauge groups with CS terms at levels $\pm k$ and four bifundamental chiral multiplets (in terms of $\mathcal{N} = 2$ multiplets). The dual geometry involved placing $N$ M2-branes at the tip of a $\mathbb{C}^4/Z_k$ singularity such that in large $N$ limit, the $\text{AdS}_4 \times S^7/Z_k$ vacuum solution of M-theory was obtained. Following this, a large number of $\mathcal{N} \geq 2$ dual pairs have been identified, with the M-theory dual of the form $\text{AdS}_4 \times Y_7$, where $Y_7$ is a (tri-)Sasaki-Einstein manifold given by the base of a certain 8d (hyper)kähler cone [6–12]. The AdS/CFT dictionary relates $\text{Vol}(Y_7)$ to the free energy $F_{S^3}$ of the dual gauge theories in the large $N$ limit [7,13]

$$F_{S^3} = - \log |Z_{S^3}| = N^{3/2} \sqrt{\frac{2\pi^6}{27 \text{Vol}(Y_7)}}. \quad (1.1)$$

This provides an important tool to compute the volumes via computations in the dual field theory.

We will consider general $\mathcal{N} = 2$ quiver gauge theories on $S^3$ with arbitrary R-charges $\Delta$’s for matter multiplets in the large $N$ limit and discover the $\hat{A}DE$ classification from requiring that the long-range forces in the resulting matrix model cancel (or equivalently, that the matrix model be local) along with a constraint on the R-charges of bifundamental matter multiplets:

$$\Delta_{(a,b)} + \Delta_{(b,a)} = 1. \quad (1.2)$$

Note that for $\mathcal{N} \geq 3$ case, this condition is automatic since the supersymmetry enhancement fixes the R-charges to be $\frac{1}{2}$ and $\hat{A}DE$ classification was presented in [14]. We will then solve the large $N$ matrix model of the $\mathcal{N} = 2$ $\hat{D}$ quiver theories$^1$, whose dual geometry involves certain 7-dimensional Sasaki-Einstein manifolds $Y_7$. Computation of their volumes directly does not necessarily give the volume for the Calabi-Yau metric necessary for the AdS/CFT correspondence $^2$. This can be circumvented by using the geometrical result of volume minimization that

---

$^1$The $\mathcal{N} = 2$ $\hat{A}$ quivers have been discussed in detail in [15] and $\hat{E}$ quivers can be solved using the approach discussed in this paper, but due to increasing complexity (and decreasing clarity) of the expressions, we refrain from giving the explicit results here.

$^2$It was not the case for $\mathcal{N} \geq 3$ theories where the hyperkähler structure guarantees the CY condition, which was used to calculate explicit volumes for toric quivers like $\hat{A}$ in [16] and nontoric ones like $\hat{D}$ in [17].
fixes the Reeb vector and gives the correct volume of the Ricci-flat Kähler manifold, which corresponds in the dual field theory to $F$-maximization that fixes the R-charges at the IR fixed point [8, 18, 19]. We will leave the check of this correspondence in the case of $\hat{D}$ quivers for future work and treat the $F_{3}$ computed in Section 3 as predicting the volumes of the relevant Sasaki-Einstein $Y_7$’s.

**Twisted Index.** Localization has also been used to compute the partition function of 3d CSm theories on $\Sigma_g \times S^1$ with a partial topological twist [20] on the Riemann surface $(\Sigma_g)$ of genus $g$ [21–23]. This partition function is usually called topologically twisted index and depends on chemical potentials $\nu \equiv A^1_f + i\sigma^f$ (complex mass parameters constructed from the background vector multiplets of the flavour symmetries) as well as background magnetic fluxes $n$ through $\Sigma_g$ for the flavour and R-symmetry. It was shown in [24] that the large $N$ limit of $\Re \log Z_{S^2 \times S^1}$ for ABJM theory reproduces the macroscopic entropy $S_{BH}$ of supersymmetric magnetic AdS$_4$ black holes discussed in [25]. The large $N$ limit for many other theories has been considered in [26, 27], which revealed a connection of Bethe potential $\mathcal{V}$ – obtained as an intermediate step while computing the twisted index – to the $F_{3}$ discussed above. In addition, an ‘index theorem’ was proven which showed that the twisted index could be written directly in terms of the $\mathcal{V}$ and its derivatives with respect to the chemical potentials.

We will again consider general $\mathcal{N} = 2$ quiver gauge theories on $\Sigma_g \times S^1$ and once again find that $\hat{A}DE$ classification follows from the requirement that the matrix model be local and the following set of constraints:

$$\nu_{(a,b)} + \nu_{(b,a)} = \frac{1}{2} \quad \text{and} \quad n_{(a,b)} + n_{(b,a)} = 1.$$  \hfill (1.3)

We will then compute the large $N$ limit of the topologically twisted index for $\hat{A}D$ quivers. Abusing the terminology slightly, we will denote $I = \log |Z_{\Sigma_g \times S^1}|$ and call it the twisted index most of the time$^3$. Along the way, we will extend the proof of the relation between the Bethe potential and the twisted index (i.e., the index theorem) to cover not just the $\hat{A}$-type quiver theories [26] but a large class of theories including the $\hat{D}$ quivers. Once again, we will not construct the dual AdS$_4$ black hole solutions to compute the entropy $S_{BH}$ explicitly (see the recent review [31] and references therein for more on twisted index and entropy matching). Assuming AdS/CFT correspondence to hold, we can conjecture that the twisted index computed in Section 4 for $\hat{A}D$ quivers is the entropy for the corresponding dual black holes (after extremization with respect to the chemical potentials), leaving an explicit check for future. However, for the specific case of the universal twist [32, 33], we provide further evidence for the AdS/CFT correspondence. In this case, due to holographic RG flow from AdS$_4$ to AdS$_2$, the black hole entropy follows a simple relation ($g > 1$):

$$S_{BH} = (g - 1)F_{3}.$$  \hfill (1.4)

The twisted index is also proportional to the free energy and a simple relation between various quantities introduced till now follows

$$S_{BH}[\frac{1}{2}] = I[\frac{1}{2}] = (g - 1) \left[ 4V[\frac{1}{2}] = F_{3}[\Delta] = \frac{4\pi N^{3/2}}{3} \mu[\Delta] \right] \quad \text{with} \quad \frac{1}{8\mu^2} = \frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)}. \hfill (1.5)$$

$^3$We will consider here field theories having M-theory duals only. Theories with type IIA duals can also be similarly considered as have been done in [28–30].
Here, $\Delta$’s are the R-charges of the bifundamental fields appearing in the $ADE$ quiver at a superconformal fixed point where $F_{S^3}$ is extremized, i.e., $\frac{\partial F_{S^3}}{\partial \Delta_{a,b}} = 0$.

**Outline.** In Section 2 we review the free energy and twisted index computation in large $N$ limit along with setting up our notation. In Section 3 we specialize to the free energy computation: we review the result for $\hat{A}_m$ quivers; provide an explicit example of $\hat{D}_4$ quiver and give the result for $\hat{D}_n$ quivers. In section 4 we move on to the twisted index computation: we provide explicit computations for $\hat{A}_3$ and $\hat{D}_4$ quivers, and present the general results for $\hat{A}_m$ and $\hat{D}_n$ quivers. In the Appendix A, we collect some derivations and proofs to make this paper self-contained. Finally, in Section 5 we discuss the end of this paper.

## 2 Review and Setup

We consider $\mathcal{N} = 2$ quiver CS gauge theories involving vector multiplets (VM) with gauge group $G[\cong \otimes a U(N_a)]$ and matter multiplets (MM) in representation $\otimes_i R_i$ of $G$. We will deal with (anti-)bifundamental and (anti-)fundamental representations only. VM consists of a gauge field $A_\mu$, an auxiliary complex fermion $\lambda_\alpha$ ($\alpha = 1, 2$) and two auxiliary real scalars $\sigma$ and $D$. MM consists of a complex scalar $\phi$, a complex fermion $\psi_\alpha$ and an auxiliary complex scalar $F$.

### 2.1 $S^3$ and Free Energy

The theories in consideration have been localized on $S^3$ in [2–4]. According to them, $Z_{S^3}$ gets localized on configurations where $\sigma_a$ in the $\mathcal{N} = 2$ VMs are constant $N_a \times N_a$ matrices and thus the original path integral reduces to a matrix model:

$$Z_{S^3} = \frac{1}{|\mathcal{W}|} \int \left( \prod_a \prod_{\text{Cartan}} d\sigma_a \right) e^{i\pi \sum_a k_a \text{tr}(\sigma_a^2)} \prod_a \det \left( 2 \sinh(\pi \alpha(\sigma_a)) \right) \prod_{\text{MM in rep } R_i} \det \left( e^{\ell(1-\Delta_i + i\rho(\sigma))} \right),$$

$$\ell(z) = \frac{i}{2\pi} \text{Li}_2 \left( e^{2\pi i z} \right) + \frac{i\pi}{2} z^2 - z \log \left( 1 - e^{2\pi i z} \right) - \frac{i\pi}{12}; \quad \ell'(z) = -\pi z \cot(\pi z),$$

where $k_a$ are the CS levels of the VM corresponding to $U(N_a)$, $\Delta_i$ are the R-charges of the corresponding MM in representation $R_i$, and $\alpha(\sigma)$, $\rho(\sigma)$ are the roots and weights of the appropriate gauge group representations. Denoting the eigenvalues of $\sigma_a$ matrices by $\lambda_{a,i}$ with $i = 1, \cdots, N_a$ leads to a simple expression for free energy:

$$F_{S^3} = -\log |Z_{S^3}| \Rightarrow Z_{S^3} = \int \prod_{a,i} d\lambda_{a,i} e^{-F_{S^3}(\lambda_{a,i})}$$

$$\Rightarrow F_{S^3} \approx -i\pi \sum_{a,i} k_a \lambda_{a,i}^2 - 2 \sum_a \sum_{i > j} \log |2 \sinh(\pi \lambda_{a,i} - \pi \lambda_{a,j})|$$

$$- \sum_{(a,b) \in E} \sum_{i,j} \ell \left( 1 - \Delta_{(a,b)} + i(\lambda_{a,i} - \lambda_{b,j}) \right) - \sum_a \sum_{\{ f \}} \sum_i \ell \left( 1 - \Delta_{f} + i \lambda_{a,i} \right).$$

---

4To our knowledge, the general result for twisted index of $\hat{A}_m$ quivers presented here is new and only certain limits of that result are available in the literature.
Here, we have included only bifundamental and fundamental representations explicitly; the (anti-)reps can be similarly added and will be added below as required. We are most concerned with the above expression’s large rank limit, keeping the CS levels fixed. For that purpose, we rewrite $N_a \to n_a N$ for some integers $n_a(\geq 1)$ and then take $N \to \infty$ by going to a continuum limit. We will mostly follow [7, 10, 14, 15, 34] in our saddle point analysis of $F_{3\text{d}}$ so most of this section has appeared before in the literature in one form or the other, apart from the explicit identification of $\mathcal{N} = 2$ $\widehat{ADE}$ quivers.

The saddle point equation following from (2.3) for $\lambda_{a,i}$ is:

$$
\frac{\partial F}{\partial \lambda_{a,i}} \propto 2 \sum_{j \neq i} \coth[\tau(\lambda_{a,i} - \lambda_{a,j})] - \sum_{b(a,b) \in E,j} \left(1 - \Delta(a,b) + i(\lambda_{a,i} - \lambda_{b,j})\right) \coth[\tau(\lambda_{a,i} - \lambda_{b,j} + i\Delta(a,b))] - \sum_{b(a,b) \in E,j} \left(1 - \Delta(a,b) - i(\lambda_{a,i} - \lambda_{b,j})\right) \coth[\tau(\lambda_{a,i} - \lambda_{b,j} - i\Delta(a,b))].
$$

(2.4)

The CS term and terms from fundamental matter are subleading compared to the vector and bifundamental contribution so we do not write them above. To take the continuum limit, we assume the eigenvalue distribution for $U(n_a N)$ to be

$$
\lambda_{a,i} \to \lambda_{a,I}(x) = N^\alpha x + iy_{a,I}(x) \quad (\text{with } I = 1, \cdots, n_a),
$$

(2.5)

and introduce an eigenvalue density $\rho(x) = \frac{1}{N} \sum_i \delta(x - x_i)$ such that $\int dx \rho(x) = 1$. This allows us to use the large argument approximation for $\coth[\tau(\lambda_{a,i} - \lambda_{b,j})] \approx \text{sgn}(x - x')$ and convert $\sum_i \to N \int dx \rho(x) \sum_I$. Note that if we demand the same number of bifundamental and anti-bifundamental matters at each edge, then no contributions arise at $\mathcal{O}(N^{1+\alpha})$. The contribution at $\mathcal{O}(N)$ then gives a constraint on $n_a$’s and R-charges as follows:

$$
\frac{\partial F}{\partial \lambda_{a,i}} \propto \left(2n_a - \sum_{b(a,b) \in E} (2 - \Delta(a,b) - \Delta(b,a))n_b\right) N \int dx' \rho(x') \text{sgn}(x - x')
$$

$$
\Rightarrow 2n_a = \sum_{b(a,b) \in E} (2 - \Delta(a,b) - \Delta(b,a))n_b.
$$

(2.6)

It is easy to see that for $\Delta(a,b) + \Delta(b,a) = 1$, we get an $\widehat{ADE}$ classification (see Figure 1) for these $\mathcal{N} = 2$ quivers just like in the $\mathcal{N} = 3$ case. This condition can also be motivated from the analysis of superpotential as discussed in [15].

---

5This is not the only solution of (2.6). For example, ABJM ($\widehat{A}_1$) and other odd $\widehat{A}$ quivers can still be constructed with the less strict condition: $\Delta(a-1,a) + \Delta(a,a-1) + \Delta(a,a+1) + \Delta(a+1,a) = 2$. We will present the off-shell expression for free energy with generic R-charges but for explicit computation of free energy, we will consider only the stricter constraint: $\Delta(a,b) + \Delta(b,a) = 1$. It would be interesting to study non-$\widehat{ADE}$ theories with non-trivial constraints on $R$-charges compatible with (2.6).
Now moving to $F_{S^3}$, we have from (2.3)

$$F_{S^3} \approx -i\pi N \int dx\rho(x) \sum_{a,l} k_a (N^\alpha x + iy_{a,l}(x))^2$$

$$- N^2 \int dx dx' \rho(x) \rho(x') \sum_{a,l,i,j} \log \left| 2 \sinh \left( \pi N^\alpha (x-x') + i\pi (y_{a,l}(x) - y_{a,i}(x')) \right) \right|$$

$$- N^2 \int dx dx' \rho(x) \rho(x') \sum_{(a,b) \in E, I,J} \sum_y \ell \left( 1 - \Delta_{(a,b)} + iN^\alpha (x-x') - (y_{a,I}(x) - y_{b,J}(x')) \right)$$

$$- N \int dx\rho(x) \sum_{a,\{f^a\},I} \ell \left( 1 - \Delta_f + iN^\alpha x - y_{a,I} \right) - N \int dx\rho(x) \sum_{a,\{f^a\},I} \ell \left( 1 - \Delta_f - iN^\alpha x + y_{a,I} \right).$$

Change variables from $N^\alpha (x-x') \to \xi$ where required and keep at most two highest orders of $N$ in each term to get$^6$

$$F_{S^3} \approx -i\pi N^{1+2\alpha} \sum_a (n_a k_a) \int dx\rho(x)x^2 + 2\pi N^{1+\alpha} \int dx\rho(x) \sum_{a,I} k_a x y_{a,I}(x)$$

$$+ \frac{1}{4\pi} N^2 - \alpha \int dx\rho(x)^2 \sum_{a,l,i,j} \arg \left( e^{2\pi i (y_{a,l}-y_{a,J} - 1/2)} \right)^2$$

$$- \frac{1}{4\pi} N^2 - \alpha \int dx\rho(x)^2 \sum_{(a,b) \in E, I,J} \sum \left( 1 - \Delta_{(a,b)} - (y_{a,I} - y_{b,J}) \right) \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)} - (y_{a,I} - y_{b,J}))} \right)^2$$

$$+ \frac{1}{3\pi} \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)} - (y_{a,I} - y_{b,J}))} \right) \left( \pi^2 - \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)} - (y_{a,I} - y_{b,J}))} \right)^2 \right) + (\Delta_{(b,a)} \text{ terms})$$

$$+ \frac{i\pi}{2} N^{1+2\alpha} \sum_a (f^a n_a - \tilde{f}^a n_a) \int dx\rho(x)x^2$$

$$+ \pi N^{1+\alpha} \sum_{a,I} \int dx\rho(x) |x| \left[ \sum_{\{f^a\}} \left( 1 - \Delta_f - y_{a,I} \right) + \sum_{\{f^a\}} \left( 1 - \Delta_f + y_{a,I} \right) \right].$$

(2.7)

Here, $f^a(\tilde{f}^a)$ are the total number of (anti)fundamental fields at node $a$. We see 3 powers of $N$ so let us assume $\sum_a n_a k_a = 0$ and $\sum_a (f^a - \tilde{f}^a) n_a = 0$ so that we can match $N^{1+\alpha} = N^{2-\alpha}$ giving us the expected $\alpha = \frac{1}{2}$. We also point out that to get non-trivial solutions, a much stricter

$^6$We use arg $\left( e^{2\pi i x} \right) = 2\pi x + 2\pi \left[ \frac{1}{2} - x \right]$ later. We have omitted divergent (as well as constant) terms that cancel due to (2.6). See Appendix A for details.
equality \( f^a = \tilde{f}^a \) needs to be imposed\(^7\) leading us to the final expression to be extremized:

\[
F_{S^3} = N^{3/2} \int dx \rho(x) \left[ 2\pi x \sum_{a,I} k_a y_{a,I}(x) + \frac{1}{4\pi} \rho(x) \left( \sum_{a,I,J} \arg \left( e^{2\pi i (y_{a,I} - y_{a,J})} \right)^2 \right) \right. \\
- \left. \sum_{(a,b) \in E} \sum_{I,J} \left[ (1 - \Delta_{(a,b)} - (y_{a,I} - y_{b,J})) \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)}) - (y_{a,I} - y_{b,J})} \right)^2 \right] \right. \\
+ \left. \frac{1}{3\pi} \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)}) - (y_{a,I} - y_{b,J})} \right) \left( \pi^2 - \arg \left( e^{2\pi i (1/2 - \Delta_{(a,b)}) - (y_{a,I} - y_{b,J})} \right)^2 \right) + (\Delta_{(b,a)} \text{ terms}) \right] \\
+ \pi |x| (2n_F - \Delta F) \right] - 2\pi \mu N^{3/2} \left( \int dx \rho(x) - 1 \right). 
\tag{2.8}
\]

We defined \( n_F = \sum_a f^n a = \sum_a \tilde{f}^a n_a, \Delta_F = \sum_a (f^n a) n_a (\Delta f^n + \bar{\Delta} f^n) \) and have added a Lagrange multiplier (\( \mu \)) term to enforce the normalizability of the eigenvalue density. On general grounds [11], extremizing \( F \) gives

\[
\tilde{F}_{S^3} = \frac{4\pi N^{3/2}}{3} \mu. 
\tag{2.9}
\]

We will sometimes use a bar to denote an on-shell quantity as in (2.9) above, when compared to the off-shell quantity given by an integral expression as in (2.8).

### 2.2 \( \Sigma g \times S^1 \) and Twisted Index

The topologically twisted index is the \( \Sigma g \times S^1 \) partition function with a topological twist along the Riemann surface of genus \( g \), \( \Sigma g \). It was derived for \( \Sigma g = S^2 \) in [21] and extended to generic \( g \) in [22]. The main result reads (we choose unit radius for the circle \( S^1 \)):

\[
Z_{\Sigma g \times S^1} = \frac{1}{|W|} \sum_{\text{a Cartan}} \left( \prod_{a} k_a u_a \right) B^g \sum_{\text{cartan}} \prod_{a} k_a u_a \prod_{\alpha \in G} \left( 1 - e^{2\pi i (u_a)} \right)^{1-g} \prod_{\alpha > 0} (-1)^{\alpha} m_a \\
\times \prod_{I} \prod_{\rho \in R_I} \left( e^{\rho(u_I) + i\nu_I} \frac{1}{1 - e^{2\pi i (u_I) + 2\pi i \nu_I}} \right), 
\tag{2.10}
\]

where \( u = i \left( \int_{S^1} A + i\sigma \right) \) are the holonomies and \( m = \frac{1}{2\pi} \int_{\Sigma g} F \) are the magnetic fluxes corresponding to the gauge group\(^8\), \( \nu = \left( \int_{S^1} A^g b_g + i\sigma^g b_g \right) \) are the holonomies (or chemical potentials) and \( n \) are the fluxes for the background vector multiplet coupled to flavour symmetry such that \( n(g - 1) \) is integer-quantized.\(^9\) The real part of \( \nu \) is defined modulo 1 so we choose \( \nu \) to satisfy \( 0 < \nu < 1 \). The Hessian \( B \) is a contribution due to fermionic zero-modes and (up to some constant factors) is given by \( B \approx \det_{a_i b_j} \frac{\partial^2 Z_{cl+1-loop}}{\partial u_a \partial m_b} \), where \( Z_{cl+1-loop} \) is the full integrand appearing in (2.10) except for the \( B^g \) factor.

As with \( Z_{S^3} \), we are interested in the large \( N \) limit of the above expression. It was studied

---

\(^7\)While solving the matrix models explicitly, we will set \( f^a = 0 \) since non-zero \( f^a \) modify the resulting expressions in a well-known (and trivial) way (see for example [34, 35]).

\(^8\)We have kept the \((-1)^{\alpha(m)}\) contribution of the vector multiplet explicitly as it contributes to the Bethe potential and is required for a consistent result, the way we take the large \( N \) limit (see Appendix A).

\(^9\)The different definitions for the same quantities corresponding to gauge and flavour groups are chosen for later convenience while comparing the large \( N \) results for twisted index to those for free energy on \( S^3 \).
for ABJM \( \hat{A}_1 \) theory in [24] and for \( \hat{A} \)-type quiver theories in [26]. As discussed there, due to the sum over magnetic fluxes, evaluating this limit becomes a two-step process: (1) Sum over magnetic fluxes, \( \mathfrak{m}_a \); (2) Integrate over the holonomies, \( u_a \). The first step involves summing a geometric series, which generates factors like \( \frac{1}{1-e^{\nu(u_a)}} \) leading to poles at \( \tilde{u}_a \) such that \( e^{\nu(u_a)} = 1 \). We solve for \( \tilde{u}_a \) by constructing an auxiliary object called the ‘Bethe potential’ \( \mathcal{V} \) defined as \( \frac{\partial \mathcal{V}}{\partial u_a} = \mathcal{B}_a^i \) such that extremizing \( \mathcal{V} \) gives the Bethe ansatz equations (BAE): \( \frac{\partial \mathcal{V}}{\partial u_a} \bigg|_{u_a = \tilde{u}_a} = \mathcal{B}_a^i (\tilde{u}_a) = 0. \tag{2.10} \mathcal{V} \) once again turns out to be related to \( F_{3\Sigma} \) so we can easily solve it in the large \( N \) limit. The second step then involves substituting this solution back in \( Z_{\Sigma \times S^1} \) and using the residue theorem to get the final result:

\[
Z_{\Sigma \times S^1} = \sum_{\tilde{u}_a \in \text{BAE}} (\mathcal{B}(\tilde{u}))^{g-1} \prod_a \prod_{a \in G} \left( 1 - e^{2\pi \alpha(\tilde{u}_a)} \right) \prod_I \prod_{\rho \in R_I} \left( \frac{e^{\pi \rho(\tilde{u}_I) + \pi i \nu_I}}{1 - e^{2\pi \rho(\tilde{u}_I) + 2\pi i \nu_I}} \right)^{(g-1)(\ell_I - 1)},
\]

(2.11)

where the Hessian can now be rewritten as \( \mathcal{B} = \det_{a,b} \frac{\partial^2 \mathcal{V}}{\partial u_a \partial u_b} \) and we have shifted the flavour flux with the R-charge \( \hat{n} = (n + \Delta) \) but we will suppress the \( \hat{\cdot} \) over \( n \) in what follows. Again, we will evaluate this final expression only in the large \( N \) limit.

### 2.2.1 Summing Fluxes

The BAES are obtained as the coefficients of \( \mathfrak{m}_a \) in the exponents from (2.10):

\[
0 = i \mathcal{B}_a^i = 2\pi k_a u_a^i + \sum_j \text{sgn}(j-i)i\pi + \sum_{b,(a,b) \in E} \sum_j \left( v'(u_a^i - u_b^j + i\nu_{(a,b)}) - v'(u_b^j - u_a^i + i\nu_{(b,a)}) \right) + \sum_{f_a} v'(u_a^i + i\nu_{f_a}) - \sum_{f_a} v'(-u_a^i + i\nu_{f_a}). \tag{2.12}
\]

These can be derived from the following Bethe potential \( \mathcal{V} \) via \( \mathcal{B}_a^i = \frac{\partial \mathcal{V}}{\partial u_a} \):

\[
\mathcal{V} = -i \sum_{a,i} \pi k_a (u_a^i)^2 + \frac{1}{2} \sum_{a,i,j} \pi \text{sgn}(j-i)(u_a^i - u_b^j) - i \sum_{(a,b) \in E} \sum_{i,j} \left( v(u_a^i - u_b^j + i\nu_{(a,b)}) + v(u_b^j - u_a^i + i\nu_{(b,a)}) \right) - i \sum_{f_a} \sum_{j} v(u_a^i + i\nu_{f_a}) - i \sum_{a,i} \sum_{f_a} v(-u_a^i + i\nu_{f_a}), \tag{2.13}
\]

where we defined, in analogy to \( \ell(z) \),

\[
v(z) = \frac{1}{2\pi} \text{Li}_2 \left( e^{2\pi z} \right) + \frac{\pi z^2}{2} - \frac{\pi}{12} \Rightarrow v'(z) = \text{Li}_1 \left( e^{2\pi z} \right) + \pi z. \tag{2.14}
\]

We chose \( v(z) \) such that \( v(0) = 0 \), however, \( v'(z) \) is divergent at \( z = 0 \).

To take the continuum limit, we again denote the eigenvalues of the \( u_a \) matrices by \( \lambda_{a,i} \) and assume the eigenvalue distribution for a node with \( U(n_a, N) \) group to be the same as before:

\[
\lambda_{a,i} \rightarrow \lambda_{a,I}(x) = N^a x + iy_{a,I}(x) \quad \text{(with } I = 1, \ldots, n_a \text{),}
\]

(2.15)

with an associated eigenvalue density \( \rho(x) \) normalized as \( \int dx \rho(x) = 1 \). We convert \( \sum_i \rightarrow
\]

\footnote{\( \mathcal{B}_a^i (\tilde{u}) = 0 \) is stricter than \( e^{\nu(u_a)} = 1 \) but we will see that the solution obtained is consistent with known results and has expected behaviour in simplifying limits of \( \nu \)'s.}
\[ N \int dx \rho(x) \sum I \] and note that we again need the same number of bifundamental and anti-bifundamental matters at each edge to cancel higher order terms. To cancel potential divergent terms (as before), we are led to a constraint relating the comarks \( n_a \)'s and chemical potentials \( \nu \)'s as follows (see Appendix A for details):

\[
\sum_a \frac{n_a^2}{2} = \sum_{(a,b) \in E} (1 - \nu_{(a,b)} - \nu_{(b,a)}) n_a n_b. \tag{2.16}
\]

We note that for \( \nu_{(a,b)} + \nu_{(b,a)} = \frac{1}{2} \), we again get an \( \widehat{ADE} \) classification for these \( N = 2 \) quivers just like the \( F_{S^3} \) as the above equation becomes equivalent to \( 2n_a = \sum_{b(a,b) \in E} n_b \). This condition can also be derived from the analysis of possible superpotential terms as discussed in [24, 26]. Thus, we are led to the same constraint on \( \alpha \) as before \((1 + \alpha = 2 - \alpha) \) implying \( \alpha = \frac{1}{2} \) and the Bethe potential in large \( N \) limit reads

\[
\mathcal{V} \approx N^{3/2} \int dx \rho(x) \left[ 2\pi x \sum_{a,I} k_a y_{a,I}(x) - \frac{1}{24\pi^2} \int dx \rho(x) \sum_{(a,b) \in E} \sum_{I,J} \left[ \arg \left( e^{2\pi i (y_{a,I} - y_{b,J} + \nu_{(a,b)}) - \frac{1}{2})} \right) \right. \right. \\
\left. \left. \times \left( \pi^2 - \arg \left( e^{2\pi i (y_{a,I} - y_{b,J} + \nu_{(b,a)}) - \frac{1}{2})} \right) \right) \right] \right. + \left. (\nu_{(b,a)} \text{ term}) \right. + \left. \pi \left| x \right| (n_F - \nu_F) \right] \\
- 2\pi \mu N^{3/2} \left( \int dx \rho(x) - 1 \right). \tag{2.17}
\]

We have again set \( \sum_a n_a k_a = 0 \), \( f^a = f^a \) and have added a Lagrange multiplier \( (\mu) \) term to enforce the normalizability of the eigenvalue density. We can also simplify the exponent by using the constraint \( \nu_{(a,b)} + \nu_{(b,a)} = \frac{1}{2} \), which will be employed below to derive the twisted index in terms of the Bethe potential. Notice the similarity and differences to the \( F_{S^3} \) expression in (2.8), especially the scaling \( N^{3/2} \) and missing vector contributions. This naively seems to suggest that \( \mathcal{V} \approx F_{S^3} \) may not hold for the larger class of theories being considered here. We will see later that it is not so. On general grounds [11], extremizing \( \mathcal{V} \) gives (just like the free energy)

\[
\overline{\mathcal{V}} = \frac{4\pi N^{3/2}}{3} \mu. \tag{2.18}
\]

It turns out that the large \( N \) limit of \( \mathcal{V} \) is not enough to compute the twisted index because \( \mathcal{V} \) has no divergences at leading order whereas the original BAEs display divergent behaviour. This behaviour follows due to bifundamental contributions involving \( v'(z) \) being divergent at \( z = 0 \) [24]. Let us separate out the divergent part of (2.12) but continue to denote rest of the finite terms as \( B'_a \) and schematically introduce exponentially small corrections as follows:

\[
0 = B'_a + \sum_{b(a,b) \in E} \sum_J \left[ v'(i(y_{a,I}(x) - y_{b,J}(x) + \nu_{(a,b)}) + e^{-N^{1/2}v^+(a,b,i,j)(x)} \right. \\
- \left. v'(i(y_{b,J}(x) - y_{a,I}(x) + \nu_{(b,a)}) + e^{-N^{1/2}v^-(a,b,i,j)(x)} \right].
\]

\[ ^{11}\text{As discussed in footnote 5, for ABJM and other odd \( \hat{A} \) quivers, the condition can be made less strict:} \nu_{(a-1,a)} + \nu_{(a,a-1)} + \nu_{(u,a+1)} + \nu_{(a+1,a)} = 1. \text{ However, we will not discuss non-\( \widehat{ADE} \) constraints in detail and stick to the stricter constraint for explicit computations.} \]
\[ \Rightarrow B'_a \approx -N^{1/2} \sum_{b,\{(a,b)\}\in E} \sum_J \left[ \delta(\delta y_{ab,1,J}(x)+\nu_{(a,b),0}) Y^+_{(a,I,b,J)}(x) - \delta(\delta y_{ab,1,J}(x)-\nu_{(b,a),0}) Y^-_{(a,I,b,J)}(x) \right], \]

(2.19)

where \( \delta(f(x),0) \) is the Kronecker delta symbol that equals 1 when \( f(x) = 0 \) and 0 otherwise. We used the following large \( N \) limit:

\[ \text{Li}_1(\exp(2\pi e^{-N^{1/2}Y(x)})) = -\log(1 - \exp(2\pi e^{-N^{1/2}Y(x)})) \approx -\log(-2\pi e^{-N^{1/2}Y(x)}) \approx +N^{1/2}Y(x). \]

Note that \( Y^\pm(x) \geq 0 \) for all \( x \) so that the exponential term is subleading and is a consistency check for explicit computations. We stress that the above equation is used to extract the saturation values of the \( y(x) \)'s as denoted by the \( \delta(\delta y(x)\pm\nu,0) \).

### 2.2.2 Integrating Holonomies

Moving back to \( Z_{\Sigma \times S^1} \), we now have to derive the large \( N \) limit of (2.11). This limit can be taken in a similar way to the Bethe potential (see Appendix A for some details) but with fixed \( \alpha = \frac{1}{2} \) such that the overall scaling of the index turns out to be \( N^{3/2} \) as expected. To cancel the divergent terms in order to get local integrands as in the case of Bethe potential, we are led to a constraint on the flavor fluxes:

\[ \sum_a n^2_a = \sum_{(a,b)\in E} (2 - n_{(a,b)} - n_{(b,a)}) n_a n_b. \]

(2.21)

Note that for \( n_{(a,b)} + n_{(b,a)} = 1 \), we recover the \( \widehat{ADE} \) classification and so we will impose this condition as we evaluate examples explicitly\(^{12}\). Finally, the large \( N \) limit of the twisted index reads (see appendix A for some details):

\[ \mathcal{I} = \log|Z_{\Sigma \times S^1}| \approx (g - 1)N^{3/2} \int dx \rho(x) \left[ \frac{1}{4\pi} \rho(x) \left( \sum_{a,I,J} \arg \left( e^{2\pi i(y_{a,I}(x)-y_{a,J}(x)-1/2)} \right)^2 \right) \right. \\

\[ - \sum_{(a,b)\in E} \sum_{I,J} \left( n_{(b,a)} \arg \left( e^{2\pi i(y_{a,I}(x)-y_{a,J}(x)-\nu_{(b,a)})} \right) \right) - \left( n_{(a,b)} \text{ term} \right) \] \\

\[ + \sum_{(a,b)\in E} \sum_{I,J} \delta(\delta y_{ab,1,J}(x)\pm\nu_{(\cdot,,0)}) n_{(\cdot)} Y^\pm_{(a,I,b,J)}(x) + \pi|x|(2n_F - n_F) \right], \]

(2.22)

where \( n_F \) is defined similar to \( \nu_F \) and the conditions on \( n_{(a,b)} \)'s and \( \nu_{(a,b)} \)'s have been used. The above expression is to be evaluated by substituting \( \{ \rho(x), y_{a,I}(x), Y^\pm_{(a,I,b,J)}(x) \} \) obtained while extremizing the Bethe potential.

**Index Theorem:** For the statement and a slick proof of the index theorem, see [26]. Here we present an enlightening proof by trying to relate \( \mathcal{I} \) to the Bethe potential \( \mathcal{V} \). First, \( \mathcal{V} \) in (2.17) is augmented by terms similar to the bifundamental contributions that look like adjoint contributions parameterized with \( \nu_a \) such that for \( \nu_a = 0 \), these adjoint terms vanish (basically

\(^{12}\)For ABJM and other odd \( \hat{A} \) quivers, the condition is less strict: \( n_{(a-1,a)} + n_{(a,a-1)} + n_{(a,a+1)} + n_{(a+1,a)} = 2 \), as expected by now.
we add 0 to \( \mathcal{V} \). Then, we can write off-shell:

\[
\mathcal{I} = (g - 1) \sum_I n_I \frac{\partial \mathcal{V}}{\partial \nu_I} \bigg|_{\nu_a = -1, \nu_a = 0},
\]

(2.23)

where \( I \) runs over all multiplets and it is understood that for vectors we set \( n_a = -1 \) and \( \nu_a = 0 \) at the end of the differentiation. This is true simply because \( \mathcal{V} \) depends on \( \nu(z) \) functions and \( \mathcal{I} \) on \( \nu'(z) \) multiplied with \( (g - 1)n \), though (2.21) has to be used to cancel some \( \frac{\pi}{2} \)'s. The Kronecker \( \delta \) contributions are also included in this form, which can be shown by using the equations of motion (2.19) and chain rule for differentiation, for example,

\[
n_{(a,b)} \frac{\partial \mathcal{V}}{\partial y_{a,I}} \frac{\partial y_{a,I}}{\partial \nu(a,b)} = n_{(a,b)} \left( \delta_{y_{ab,l},I(x) + \nu(a,b),0} Y^+_{(a,l,b,l)}(x) \right) (+1),
\]

(2.24)

which is what appears in (2.22). The \( n_{(b,a)} Y^-(x) \) term with proper sign also similarly follows. Thus, we have proven that the twisted index can be obtained from the Bethe potential and this relation is valid for a larger class of theories than considered in [26].

The above formula focusses (mostly) on the integrands and under certain conditions (deduced from the discussion below), it is valid even after the integration is done (i.e., on-shell) with the understanding that \( I \) runs only over the matter chemical potentials (since vector \( \nu_a \)'s are set to zero already at the level of integrand):

\[
\mathcal{I} = (g - 1) \sum_I n_I \frac{\partial \mathcal{V}}{\partial \nu_I}.
\]

(2.25)

For (anti-)fundamental matter contributions, we can take \( \nu_I = n_F - \nu_F \) and \( n_I = 2n_F - n_F \) and the above relation continues to hold. Note that we are allowed to choose a suitable basis for the \( n \)'s and \( \nu \)'s by including even redundant combinations to simplify the computation at hand. However, to keep the expression for \( \mathcal{V} \) tractable, the conditions on \( \nu_{(a,b)} \) and \( n_{(a,b)} \) may need to be imposed and that makes the sum over \( I \) for all bifundamentals ill-defined leading to violation of (2.25). To remedy this issue, let us compare what happens to the sum \( \sum_{(a,b)\oplus(b,a)} \) if the two constraints \( \nu_{(a,b)} + \nu_{(b,a)} = \frac{1}{2} \) and \( n_{(a,b)} + n_{(b,a)} = 1 \) are imposed after and before the differentiation:

After:

\[
\sum_I n_I \frac{\partial \mathcal{V}}{\partial \nu_I} = n_{(a,b)} \frac{\partial \mathcal{V}(\nu_{(a,b)}, \cdots)}{\partial \nu_{(a,b)}} + n_{(b,a)} \frac{\partial \mathcal{V}(\nu_{(b,a)}, \cdots)}{\partial \nu_{(b,a)}} + \cdots
\]

\[
= n_{(a,b)} \mathcal{V}'(\nu_{(a,b)}, \cdots) + (1 - n_{(a,b)}) \mathcal{V}'(\nu_{(b,a)}, \nu_{(a,b)}, \cdots) + \cdots
\]

(2.26)

Before:

\[
\sum_I n_I \frac{\partial \mathcal{V}}{\partial \nu_I} = n_{(a,b)} \left( \mathcal{V}'(\nu_{(a,b)}, \cdots) - \mathcal{V}'(\nu_{(b,a)}, \nu_{(a,b)}, \cdots) \right) + \cdots
\]

\[
= \sum_I n_I \frac{\partial \mathcal{V}}{\partial \nu_I} - \mathcal{V}'(\frac{1}{2} - \nu_{(a,b)}, \cdots),
\]

(2.27)

where \( \sum' \) denotes sum over independent set of \( \nu \)'s, which seems to be missing a term when
compared to the full $\sum$. Let us look at the following expression now:

$$\sum' \nu_l \frac{\partial \hat{V}}{\partial \nu_l} = \nu(a,b) \left( \hat{V}'(\nu(a,b), \ldots) - \hat{V}'(\frac{1}{2} - \nu(a,b), \ldots) \right) + \cdots$$

$$= \nu(a,b) \hat{V}'(\nu(a,b), \ldots) + \left( \frac{1}{2} - \nu(a,b) \right) \hat{V}'(\frac{1}{2} - \nu(a,b), \ldots) - \frac{1}{2} \hat{V}'(\frac{1}{2} - \nu(a,b), \ldots) + \cdots$$

$$= \sum \nu_l \frac{\partial \hat{V}}{\partial \nu_l} + \frac{1}{2} \hat{V}'(\frac{1}{2} - \nu(a,b), \ldots), \quad \text{(2.28)}$$

where the last term is half of the extra term found in (2.27). Now, the index theorem follows:

$$\mathcal{I} = (g - 1) \sum n_l \frac{\partial \hat{V}}{\partial \nu_l} = (g - 1) \left[ \sum' n_l \frac{\partial \hat{V}}{\partial \nu_l} + 2 \left( \sum \nu_l \frac{\partial \hat{V}}{\partial \nu_l} - \sum' \nu_l \frac{\partial \hat{V}}{\partial \nu_l} \right) \right]$$

$$= (g - 1) \left[ \sum 2\nu_l \frac{\partial \hat{V}}{\partial \nu_l} + \sum (n_l - 2\nu_l) \frac{\partial \hat{V}}{\partial \nu_l} \right]$$

$$\Rightarrow \quad \mathcal{I} = (g - 1) \left[ 4\hat{V} + \sum (n_l - 2\nu_l) \frac{\partial \hat{V}}{\partial \nu_l} \right]. \quad \text{(2.29)}$$

We used the ‘homogeneous’ property of $\hat{V}$ such that $\sum \nu_l \frac{\partial \hat{V}}{\partial \nu_l} = 2\hat{V}$ (proven in appendix A) to write the first term. We will also see later that $4\hat{V}[\nu] = \hat{F}_{S^3}[2\nu]$ for the $\widetilde{A\bar{D}}$ quivers. The $2\nu$’s here become the R-charges $\Delta$’s in $F_{S^3}$ for this comparison, as can be expected from the constraints imposed on them to get $\widetilde{A\bar{D}}$ classification. In general, $\mathcal{I}$ needs to be extremized with respect to $\nu$’s and critical values for $\nu$’s are obtained in terms of the flavour fluxes $n$’s. The resulting expression $\mathcal{I}(\nu(n), n)$ is supposed to match the corresponding black hole entropy $S_{BH}$ as discussed in Section 1. However, for the case of universal twist, $n_l = 2\nu_l \ [32,33]$ leading to the expected simple relation

Universal twist: $S_{BH} = \mathcal{I} = (g - 1)4\hat{V} = (g - 1)\hat{F}_{S^3}$ given that $\frac{\partial \hat{V}}{\partial \nu_l} = \frac{\partial \hat{F}_{S^3}}{\partial \nu_l} = 0. \quad \text{(2.30)}$

This completes the general setup of the two quantities ($F_{S^3}$ and $\mathcal{I}$) to be considered in this paper. Let us now turn to explicit computation of the free energy of $\widetilde{A\bar{D}}$ quivers.

### 3 Free Energy and Volume

In this section, we consider the $\widetilde{A\bar{D}}$ quivers and evaluate their free energy, or equivalently the Vol($Y_7$). We will follow the algorithm developed in [34] but suitably modified for the case of general R-charges. We briefly review it here to introduce the terminology we use when writing down the explicit solutions.

**Algorithm.** We take the principle value for the arg() functions leading to the inequalities:

$$0 < y_{a,I} - y_{a,J} < 1; \quad 0 < y_{a,I} - y_{b,J} + \Delta_{(a,b)} < 1, \quad -1 < y_{a,I} - y_{b,J} - \Delta_{(b,a)} < 0.$$  \quad \text{(3.1)}$$

$$\Rightarrow |y_{a,I} - y_{a,J}| < 1; \quad -\Delta_{(a,b)} < y_{a,I} - y_{b,J} < \Delta_{(b,a)}.$$  

As discussed in previous section, we will insist $\Delta_{(a,b)} + \Delta_{(b,a)} = 1$. Since we have pairing up of bifundamentals, while the inequalities are not violated, the contribution from these fields to
(2.8) simplifies:

\[- \sum_{(a,b) \neq (b,a)} \pi \left( 2 - \Delta^+_\{a,b\} \right) \int dx \rho(x)^2 \sum_{I,J} \left[ (y_{a,I} - y_{b,J} + \frac{\Delta^-_{a,b}}{2})^2 + \frac{1}{12} (3 - \Delta^+_\{a,b\}) (1 - \Delta^+_\{a,b\}) \right] \]

\[= - \sum_{(a,b) \neq (b,a)'} \pi \int dx \rho(x)^2 \sum_{I,J} (y_{a,I} - y_{b,J} + \frac{\Delta^-_{a,b}}{2})^2, \tag{2.9} \]

where \(\Delta^\pm_{a,b} = \Delta_{a,b} \pm \Delta_{(b,a)}\). We will also insist that all \(y_{a,I}(x) - y_{a,J}(x) = 0\) initially, which simplifies the vector contribution to just \(\sum_a \int dx \rho(x)^2 \sum_{I,J} \frac{\Delta^-_{a,b}}{2}\).

Extremizing \(F_{S^3}\) now with respect to \(y(x)\)‘s and \(\rho(x)\), we find a solution which is consistent only in a bounded region around the origin \((x = 0)\). This is because as \(|x|\) increases, the differences \(y_{a,I}(x) - y_{a,J}(x) \equiv \delta y_{a,I}(x)\) monotonically increase (or decrease), saturating at least one of the inequalities given above at some point on either side of \(x = 0\), which we label as \(x^\pm_1\). This saturation is maintained beyond these points, requiring the corresponding \(y_{a,I}(x)\)’s to either bifurcate (for \(n_a > 1\)) or develop a kink. Once an inequality is saturated, we have to remove one of the \(y(x)\)’s from the integral expression (2.8) by using the saturation value and solve the revised equations of motion separately on both positive and negative side of the \(x\)-axis until new saturation points are encountered on both sides. This leads to pair of regions on either side of the central region (or region 1), which we will label as “region 2\(^{\pm}\)” bounded by \(x^\pm_2\) for obvious reason. This procedure needs to be iterated until either all \(y(x)\)’s get related or \(\rho(x) = 0\), determining a maximum of \(\sum_a n_a\) regions for \(\hat{A}\) quivers and \(\sum_a n_a - 1\) regions for \(D\bar{E}\) quivers\(^\text{13}\). Once the eigenvalue density \(\rho(x)\) is determined in all the regions, the value of \(\mu\) is found from the normalization condition of \(\rho(x)\), which gives the quantities we want via the following relations:

\[\bar{F}_{S^3} = \frac{4\pi N^{3/2}}{3} \mu; \quad \frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{8\mu^2}.\tag{3.3}\]

We combined the former equation with (1.1) to get the latter.

### 3.1 \(\hat{A}_m\) Revisited

We review the \(\hat{A}\) quivers dealt succinctly in [15]. The above discussion applies to this case just by setting the values of \(I, J = 1\). The contribution from bifundamentals (3.2) can be rewritten as \(\bar{F}\) given by eq (4.2) of [15]. The solution for free energy is given in terms of the area of the following polygon:

\[\mathcal{P} = \left\{ (s, t) \in \mathbb{R}^2 : \sum_{a=1}^{m+1} |t + q_a s| + c_1 t + c_2 s \leq 1 \right\}; \quad c_1 \equiv \sum_{(a,b) \in E} \Delta^-_{a,b}; \quad c_2 \equiv \sum_{(a,b) \in E} q_a \Delta^-_{a,b}. \tag{3.4}\]

The redefined CS levels \(q_a\) are constrained parameters obeying \(\sum_{a=1}^{m+1} q_a = 0\) and are related to \(k_a\)’s as follows:

\[q_a = k_a - k_{a+1}, \quad a = 1, \ldots, m; \quad q_{m+1} = k_{m+1} - k_1.\tag{3.5}\]

\(^\text{13}\)We count disjointed \(n^\pm\) regions as one single region so \(\hat{A}_1\) has two \(\hat{A}_1\) has two regions, even though there are four saturation points bounding three apparent regions \(\{2^-, 1^-, 2^+\}\).
The Area($\mathcal{P}$) is related to $\int dx \rho(x)$ such that we get\(^{14}\)

$$
\frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{8\mu^2} = \frac{1}{2} \text{Area}(\mathcal{P}) = \frac{1}{4} \sum_{a=1}^{m+1} \left[ \frac{|\gamma_{a,a+1}|}{\sigma_a} + \frac{|\gamma_{a,a+1}|}{\sigma_{a+m+1}} \right].
$$

This reduces to the correct $\mathcal{N} = 3$ expression when all $\Delta_{(a,b)} = \frac{1}{2}$ as can be directly checked from the definition of $\sigma$'s:

$$
\beta_a = \left( \frac{1}{q_a} \right) \text{ for } a = 1, \cdots, m + 1, \quad \beta_{m+2} = -\beta_1; \quad \gamma_{a,b} = \beta_a \wedge \beta_b;
$$

$$
\sigma_a = \sum_{b=1}^{m+1} \left[ |\gamma_{a,b}| + \gamma_{b,a} \Delta_{-(b,b+1)}^- \right], \quad \sigma_{a+m+1} = \sum_{b=1}^{m+1} \left[ |\gamma_{a,b}| - \gamma_{b,a} \Delta_{-(b,b+1)}^- \right].
$$

A trivial example to check the above formulas is $\mathcal{A}_1$ quiver (choose the ordering $q_1 \geq 0 \geq q_2$ and $q_1 = \frac{k}{2}$):

$$
\frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{4} \left( \frac{2q_1}{(4q_1 \Delta_{(1,2)}^+) + (4q_1 \Delta_{(2,1)}^+) + (4q_1 \Delta_{(1,2)}^+ \Delta_{(2,1)}^+)} + \frac{2q_1}{(4q_1 \Delta_{(1,2)}^- \Delta_{(2,1)}^-)} \right) = \frac{1}{32 \Delta_{(1,2)}^- \Delta_{(2,1)}^- \Delta_{(1,2)}^- \Delta_{(2,1)}^-} q_1.
$$

This expression appears in literature a lot and it can be straightforwardly checked that it reproduces the correct $\frac{1}{k}$ for ABJM theory when all $\Delta$'s equal $\frac{1}{2}$. A slightly non-trivial example is $\mathcal{A}_3$ but we will discuss it for twisted index in the next section.

Let us move on to the $\mathcal{D}$ quivers now (specifically $\mathcal{D}_4$ which is related to $\mathcal{A}_3$ via unfolding procedure in the $\mathcal{N} = 3$ case [34,36]).

### 3.2 $\mathcal{D}_4$ Solved

We give the detailed solution for the $\mathcal{D}_4$ quiver here and to make the expressions easier to read, we do a bit of housekeeping first. Let us redefine the five constrained CS levels $k$'s to four unconstrained variables $p$'s as follows:

$$
k_1 = -(p_1 + p_2), \quad k_2 = p_1 - p_2, \quad k_3 = p_3 - p_4, \quad k_4 = p_3 + p_4, \quad k_5 = p_2 - p_3.
$$

We will also suppress the second index on the four $y_{a,1}$ with $a = 1, \cdots, 4$. Furthermore, we introduce a ‘vector’ of R-charges:

$$
\alpha_b(\Delta^-) = \left\{ \frac{1}{2}(\Delta^-_{(1,5)} - \Delta^-_{(2,5)}), \frac{1}{2}(\Delta^-_{(1,5)} + \Delta^-_{(2,5)}), -\frac{1}{2}(\Delta^-_{(4,5)} + \Delta^-_{(3,5)}), \frac{1}{2}(\Delta^-_{(4,5)} - \Delta^-_{(3,5)}) \right\},
$$

which will appear in a combination $\sum_{b=1}^{4} p_b \alpha_b(\Delta^-) \equiv p \cdot \alpha(\Delta^-)$ below. For generic $p$'s, there are going to be 5 regions consisting of one central region spanning both negative and positive side of the $x$-axis and 4 pairs of disjointed regions beyond the central one as explained in the algorithm above. Let us now enumerate the solution in each region for a particular ordering $p_1 \geq p_2 \geq p_3 \geq p_4 \geq 0$.

\(^{14}\)It is a fun exercise to show that the definition of $\mathcal{P}$ as given in (3.4) can be ‘integrated’ to get precisely the area of $\mathcal{P}$ as given in (3.6) [11].
Region 1: \[ -\frac{2\mu}{4(p_1+p_2)-2p_\alpha(\Delta^-)} \leq x \leq \frac{2\mu}{4(p_1+p_2)+2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \frac{1}{2} \mu - \frac{1}{2} xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = -\frac{1}{2} \Delta_1^{(1,5)} + \frac{x(p_1+p_2)}{-\mu+xp_\alpha(\Delta^-)}; \quad y_2 - y_{5,2} = -\frac{1}{2} \Delta_1^{(2,5)} + \frac{x(-p_1+p_2)}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_3 - y_{5,2} = -\frac{1}{2} \Delta_3^{(3,5)} + \frac{x(-p_1+p_3+p_4)}{-\mu+xp_\alpha(\Delta^-)}; \quad y_4 - y_{5,2} = -\frac{1}{2} \Delta_3^{(4,5)} - \frac{x(p_1+p_3+p_4)}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_{5,1} - y_{5,2} = 0. \]

Region 2\(^-\): \[ -\frac{2\mu}{4p_1-2p_\alpha(\Delta^-)} \leq x \leq -\frac{2\mu}{4p_1+2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \frac{1}{2} \mu - \frac{1}{2} xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = 1 - \Delta_1^{(1,5)}; \quad y_2 - y_{5,2} = \frac{1}{2} (1 - \Delta_1^{(2,5)}) - \frac{2xp_1}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_3 - y_{5,2} = \frac{1}{2} (1 - \Delta_3^{(3,5)}) - \frac{x(p_1+p_2+p_3-p_4)}{-\mu+xp_\alpha(\Delta^-)}; \quad y_4 - y_{5,2} = \frac{1}{2} (1 - \Delta_3^{(4,5)}) - \frac{x(p_1+p_2+p_3+p_4)}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_{5,1} - y_{5,2} = 1 - \frac{2x(p_1+p_2)}{-\mu+xp_\alpha(\Delta^-)}. \]

Region 2\(^+\): \[ \frac{2\mu}{4(p_1+p_2)+2p_\alpha(\Delta^-)} \leq x \leq \frac{2\mu}{4p_1+2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \frac{1}{2} \mu - \frac{1}{2} xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = -\Delta_1^{(1,5)}; \quad y_2 - y_{5,2} = -\frac{1}{2} (1 + \Delta_1^{(2,5)}) - \frac{2xp_1}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_3 - y_{5,2} = \frac{1}{2} (1 - \Delta_3^{(3,5)}) - \frac{x(p_1+p_2+p_3-p_4)}{-\mu+xp_\alpha(\Delta^-)}; \quad y_4 - y_{5,2} = \frac{1}{2} (1 - \Delta_3^{(4,5)}) - \frac{x(p_1+p_2+p_3+p_4)}{-\mu+xp_\alpha(\Delta^-)}; \]
\[ y_{5,1} - y_{5,2} = 1 - \frac{2x(p_1+p_2)}{-\mu+xp_\alpha(\Delta^-)}. \]

Region 3\(^-\): \[ -\frac{2\mu}{2(p_1+p_2+p_3+p_4)-2p_\alpha(\Delta^-)} \leq x \leq -\frac{2\mu}{4p_1-2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \mu + xp_1 - xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = 1 - \Delta_1^{(1,5)}; \quad y_2 - y_{5,2} = -\Delta_1^{(2,5)}; \quad y_3 - y_{5,2} = -\frac{1}{2} \Delta_3^{(3,5)} - \frac{x(p_2+p_3-p_4)}{-2\mu-2xp_1+2p_\alpha(\Delta^-)}; \]
\[ y_4 - y_{5,2} = -\frac{1}{2} \Delta_3^{(4,5)} - \frac{x(p_2+p_3+p_4)}{-2\mu+2xp_1+2p_\alpha(\Delta^-)}; \]
\[ y_{5,1} - y_{5,2} = -\frac{2xp_2}{-2\mu+2xp_1+2p_\alpha(\Delta^-)}. \]

Region 3\(^+\): \[ \frac{2\mu}{4p_1+2p_\alpha(\Delta^-)} \leq x \leq \frac{2\mu}{4p_1+2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \mu + xp_1 - xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = -\Delta_1^{(1,5)}; \quad y_2 - y_{5,2} = 1 - \Delta_1^{(2,5)}; \quad y_3 - y_{5,2} = -\frac{1}{2} \Delta_3^{(3,5)} - \frac{x(p_2+p_3-p_4)}{-2\mu+2xp_1+2p_\alpha(\Delta^-)}; \]
\[ y_4 - y_{5,2} = -\frac{1}{2} \Delta_3^{(4,5)} - \frac{x(p_2+p_3+p_4)}{-2\mu+2xp_1+2p_\alpha(\Delta^-)}; \]
\[ y_{5,1} - y_{5,2} = -\frac{2xp_2}{-2\mu+2xp_1+2p_\alpha(\Delta^-)}. \]

Region 4\(^-\): \[ -\frac{2\mu}{2(p_1+p_2+p_3+p_4)-2p_\alpha(\Delta^-)} \leq x \leq -\frac{2\mu}{2(p_1+p_2+p_3+p_4)-2p_\alpha(\Delta^-)} \]
\[ \rho(x) = \frac{3}{2} \mu + \frac{1}{2} x(3p_1 + p_2 + p_3 + p_4) - \frac{3}{2} xp \cdot \alpha(\Delta^-); \]
\[ y_1 - y_{5,2} = 1 - \Delta_1^{(1,5)}; \quad y_2 - y_{5,2} = -\Delta_1^{(2,5)}; \]
\[ y_3 - y_{5,2} = -\frac{1}{6} \frac{1}{2} \Delta_3^{(3,5)} + \frac{2x(p_2-p_3)}{-9\mu-3x(3p_1+p_2+p_3+p_4)+9xp_\alpha(\Delta^-)}; \quad y_4 - y_{5,2} = -\Delta_3^{(4,5)}; \]
\[ y_{5,1} - y_{5,2} = -\frac{1}{3} + \frac{2x(-2p_2+p_3+p_4)}{-9\mu-3x(3p_1+p_2+p_3+p_4)+9xp_\alpha(\Delta^-)}. \]
Region 4+: $$\frac{2\mu}{2(p_1+p_2+p_3+p_4)+2p\alpha(\Delta^-)} \leq x \leq \frac{2\mu}{2(p_1+p_2+p_3-p_4)+2p\alpha(\Delta^-)}$$

$$\rho(x) = \frac{3}{2} \mu - \frac{1}{2} x (3p_1 + p_2 + p_3 + p_4) - \frac{3}{2} x p \cdot \alpha(\Delta^-);$$

$$y_1 - y_{5,2} = -\Delta(1,5), \quad y_2 - y_{5,2} = 1 - \Delta(2,5),$$

$$y_3 - y_{5,2} = \frac{1}{6} - \frac{1}{2} \Delta^- (3,5) + \frac{2 \mu (2p_4 - p_3 - 2p_2)}{9\mu + 3x(3p_1 + p_2 + p_3 + p_4) + 2xp\alpha(\Delta^-)}, \quad y_4 - y_{5,2} = 1 - \Delta(4,5);$$

$$y_{5,1} - y_{5,2} = \frac{1}{3} + \frac{2 \mu (2p_3 + p_4)}{9\mu + 3x(3p_1 + p_2 + p_3 + p_4) + 2xp\alpha(\Delta^-)}.$$  

Finally, the last saturation occurs at the end of this region with $$y_{5,1} - y_{5,2} = -1.$$

Region 5+: $$\frac{2\mu}{2(p_1+p_2+p_3-p_4)+2p\alpha(\Delta^-)} \leq x \leq \frac{2\mu}{2(p_1+p_2)+2p\alpha(\Delta^-)}$$

$$\rho(x) = 2\mu + x(2p_1 + p_2 + p_3) - 2xp \cdot \alpha(\Delta^-);$$

$$y_1 - y_{5,2} = 1 - \Delta(1,5), \quad y_2 - y_{5,2} = -\Delta(2,5), \quad y_3 - y_{5,2} = -\Delta(3,5),$$

$$y_4 - y_{5,2} = -\Delta(4,5), \quad y_{5,1} - y_{5,2} = \frac{1}{2} - \frac{x(p_2-p_3)}{4\mu - 2x(2p_1 + p_2 + p_3) + 4xp\alpha(\Delta^-)}.$$  

Finally, the last saturation occurs at the end of this region with $$y_{5,1} - y_{5,2} = 1.$$ 

Let us visualize all these expressions for $$\rho(x)$$ and $$y(x)$$’s in Figure 2 using the numerical values: $$p_1 = 15, p_2 = 8, p_3 = 4, p_4 = 1$$ and all $$\Delta$$’s equal to $$\frac{2}{3}.$$  

![Figure 2: Eigenvalue density $$\rho(x)$$ and distributions $$y_{a,f}(x)$$ for $$\hat{D}_4$$ quiver ($$y_{5,2}(x) = 0$$).](image)

With the $$\rho(x)$$ known in all the regions, we can just use the normalization condition $$\int dx \rho(x) = 1$$ to get $$\frac{1}{\mu^2},$$ which is directly related to the Vol(Y7). As with the $$\hat{A}$$ quiver, this
volume can be recast as a polygon’s area and for $\hat{D}_4$ quiver, this polygon turns out to be
\[
\mathcal{P} = \left\{ (s,t) \in \mathbb{R}^2 \mid \sum_{a=1}^{n} \left( |t + p_a s| + |t - p_a s| \right) - 4|t| + 2p \cdot \alpha(\Delta^-) s \leq 1 \right\},
\]
with \( \frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{4} \text{Area}(\mathcal{P}) \). \hfill (3.11)

Figure 3: Polygon $\mathcal{P}$ for $\hat{D}_4$ quiver. ($s - t$ coordinate system rotated by $\frac{\pi}{2}$.)

For the above mentioned numerical values, the polygon is shown in Figure 3 with \( \frac{1}{4} \text{Area}(\mathcal{P}) = \frac{1992856091659101}{388764834312025600} \approx 0.005 \). This value matches \( \frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{8\mu^2} \) exactly. Also, note that this construction is valid for all possible orderings and signs of $p$’s. We can, of course, write the explicit volume for $\hat{D}_4$ here but instead we prefer to give the explicit expression for general $\hat{D}_n$ quiver directly.

### 3.3 $\hat{D}_n$ Result

Given the result for $\hat{D}_4$ quiver above and the known results for $N = 3$ quivers, we conjecture the polygon for $N = 2$ $\hat{D}_n$ quivers to be:
\[
\mathcal{P} = \left\{ (s,t) \in \mathbb{R}^2 \mid \sum_{a=1}^{n} \left( |t + p_a s| + |t - p_a s| \right) - 4|t| + c s \leq 1 \right\}; \quad c \equiv \sum_{b=1}^{n} (2p_b)\alpha_b(\Delta^-), \hfill (3.12)
\]
\[
\alpha_b(\Delta^-) = \left\{ \frac{1}{2}(\Delta^-_{(1,5)} + \Delta^-_{(2,5)}), \frac{1}{2}(\Delta^-_{(1,5)} - \Delta^-_{(2,5)}), \Delta^-_{(5,6)}, \ldots, \Delta^-_{(n,n+1)} \right\} \quad \text{and} \quad -\frac{1}{2}(\Delta^-_{(4,n+1)} + \Delta^-_{(3,n+1)}), -\frac{1}{2}(\Delta^-_{(4,n+1)} - \Delta^-_{(3,n+1)}). \hfill (3.13)
\]

For generic $n$, the $p$’s are related to the CS levels as follows:
\[
k_1 = -(p_1 + p_2), \quad k_2 = p_1 - p_2, \quad k_3 = p_{n-1} - p_n, \quad k_4 = p_{n-1} + p_n, \quad k_i = p_{i-3} - p_{i-2}; \quad i = 5, \ldots, n + 1. \hfill (3.14)
\]

Note the difference with (3.4) for $\hat{A}$ quivers which requires two constants. As explained in [15], this is due to the two $U(1)$ isometries of the toric $\hat{A}$ quivers so it makes sense that for the case of non-toric $\hat{D}$ quivers which has only one $U(1)$ isometry, we see only one constant in the polygon formula (3.12).

One can verify that this polygon’s area gives the general volume formula corresponding to $\hat{D}_n$ quivers:
\[
\frac{\text{Vol}(Y_7)}{\text{Vol}(S^7)} = \frac{1}{8\mu^2} = \frac{1}{4} \text{Area}(\mathcal{P}) = \frac{1}{4} \sum_{a=0}^{n} \left[ \frac{|\gamma_{a,a+1}|}{\sigma_a^+ \sigma_{a+1}^+} + \frac{|\gamma_{a,a+1}|}{\sigma_a^- \sigma_{a+1}^-} \right], \hfill (3.15)
\]
which we have explicitly checked for \( \hat{D}_5, \cdots, \hat{D}_{10} \). The definitions of various quantities are slightly elaborate here:

\[
\beta_0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \beta_{\pm a} = \begin{pmatrix} 1 & \pm a \\ 0 \end{pmatrix} \quad \text{for } a = 1, \ldots, n, \quad \beta_{n+1} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \quad \gamma_{a,b} = \beta_a \wedge \beta_b;
\]

\[
\bar{\sigma}_a^\pm = \sum_{b=1}^n \left[ |\gamma_{a,b}| + |\gamma_{a,-b}| \pm (\gamma_{a,b} - \gamma_{a,-b})\alpha_b (\Delta^-) \right] - 4|\gamma_{a,n+1}|. \quad (3.16)
\]

The combination \((\gamma_{a,b} - \gamma_{a,-b}) = 2p_b \) for \( a \neq 0 \) is used to show similarity with the definitions for \( \hat{A} \) quivers in (3.7), otherwise it is a simple factor defining \( c \) in (3.12).

This completes the free energy or dual volume computation of \( \hat{A}D \) quivers. Let us now continue with the computation of their twisted indices.

## 4 Twisted Index and Entropy

Let us again work on \( \hat{A}D \) quivers and evaluate (2.17) and (2.22). We will follow the same algorithm used to evaluate \( F_{S^3} \) but start with the reduced set of inequalities:

\[
0 < y_{a,I} - y_{b,J} + \nu_{(a,b)} < 1; \quad -1 < y_{a,I} - y_{b,J} - \nu_{(b,a)} < 0. \quad (4.1)
\]

As discussed previously, we will insist \( \nu_{(a,b)} + \nu_{(b,a)} = \frac{1}{2} \). Since we have pairing up of bifundamentals, while the inequalities are not violated, the contribution from these fields simplify to

\[
- \sum_{(a,b)\oplus(b,a)} \pi \left( 1 - \nu_{(a,b)}^+ \right) \int dx \rho(x)^2 \sum_{I,J} \left[ \left( y_{a,I} - y_{b,J} + \frac{\nu_{(a,b)}^-}{2} \right)^2 - \frac{1}{12} \nu_{(a,b)}^+ \left( 2 - \nu_{(a,b)}^- \right) \right]
\]

\[
= - \sum_{(a,b)\oplus(b,a)} \frac{\pi}{2} \int dx \rho(x)^2 \sum_{I,J} \left[ \left( y_{a,I} - y_{b,J} + \frac{\nu_{(a,b)}^-}{2} \right)^2 - \frac{1}{16} \right], \quad (4.2)
\]

where \( \nu_{(a,b)}^\pm = \nu_{(a,b)} \pm \nu_{(b,a)} \). Comparing (2.8) and (3.2) in the central region (i.e., \( y_{a,I} = y_{a,J} \)) with (2.17) and (4.2), we find that the two expressions (whether off-shell or on-shell) are same up to the scalings given in Table 1.

| Free Energy | \( \rightarrow \) | Bethe Potential |
|-------------|-----------------|----------------|
| \( F_{S^3} \) | \( \rightarrow \) | \( 4V \) |
| \( \mu \) | \( \rightarrow \) | \( 4\bar{\mu} \) |
| \( \Delta \) | \( \rightarrow \) | \( 2\nu \) |
| \( y \) | \( \rightarrow \) | \( 2y \) |
| \( x \) | \( \rightarrow \) | \( 2x \) |
| \( \rho \) | \( \rightarrow \) | \( \frac{1}{2}\rho \) |

Table 1: Scaling different parameters to relate \( F_{S^3} \) and \( V \). Note that these scalings are different than those of [26].

\(^{15}\)It is interesting to note that the \( \pm \) structure in (3.15) produces independent terms, which is in contrast to the expression (3.6) of \( \hat{A} \) quivers, where the analogous \( \sigma^+ \) and \( \sigma^- \) terms produce one mixed term. However, that’s just an artifact of the way we have defined \( \beta \)'s. \( \beta_0 \) is quite redundant if we realize \( \frac{1}{a_0 a_1^*} + \frac{1}{a_0 a_1} = \frac{|a_0 - a_1|}{a_0 a_1 a_1^*} \).
Once an inequality is saturated, we have to use the general expression involving arg() functions. This step is to be taken much more seriously here than the case of free energy because moving away from the central region generates terms like \((y_{a,I} - y_{a,J})^2\) leading to new inequalities:

\[
-\frac{1}{2} < y_{a,I} - y_{a,J} < 0 \quad \text{or} \quad 0 < y_{a,I} - y_{a,J} < \frac{1}{2},
\]

which can drastically affect the evaluation of \(V\) in the new regions. This process of generation of new terms and inequalities that look like coming from vector contributions of \(F_{S^3}\) means that \(V\) can indeed be related to \(F_{S^3}\) in all the regions, not just in the central region, even though these two expressions seemed very different for \(\hat{D}\hat{E}\) quivers in subsection 2.2.1. In fact, using the scalings given in Table 1, we can verify that it is indeed so allowing us to use the results for \(F_{S^3}\) to write down \(V\) for the same quiver.

As far as saturation points, \(\rho(x)\) and \(y_{a,I}(x)\) are concerned, we can get them from the similar computations already done for \(F_{S^3}\) but to get the divergent contributions \(Y^{\pm}(x)\), we need to perform one more step during extremization of \(V\) in different regions. This step is to substitute the solutions of each region \(n^\pm\) in the equations of motion \(B_a^I\) found in the region 1. Of course, \(B_a^I \neq 0\) in other regions but provide the divergent contributions \(Y^{\pm}(x)\)'s via (2.19).

One technicality is that the \(B_a^I\) of (2.19) are related to the equations of motion obtained from \(V\) via \(\frac{\partial V}{\partial y_{a,I}} = \hat{N}\rho(x)B_a^I\).

### 4.1 \(\hat{A}_3\) Solved

As far as we know, only theories like \(\hat{A}_1\) (ABJM) quiver whose matrix models involve just 2 regions have been discussed in the literature. So we improve the situation by considering a non-trivial example explicitly for \(\hat{A}\) quivers: \(\hat{A}_3\), whose matrix model involves 4 regions. Let us set up some notation before presenting the explicit solution. We use the redefined CS variables following (3.5) with the given ordering: \(q_1 > q_2 > 0 > q_3\) and \(q_4 = -\sum_{a=1}^{3} q_a\). We will again suppress the second index on the four \(y_{a,1}\) with \(a = 1, \cdots, 4\) and introduce two short-hand notations:

\[
\Sigma_{\nu} = \nu^{(1,2)}_{(2,3)} + \nu^{(3,4)}_{(4,1)} ; \\
\alpha_b(\nu^-) = \left\{ \left( \nu^{(1,2)}_{(2,3)} - \nu^{-(4,1)}_{(4,1)} \right), \left( \nu^{-(2,3)}_{(2,3)} - \nu^{-(4,1)}_{(4,1)} \right), \left( \nu^{(3,4)}_{(3,4)} - \nu^{-(4,1)}_{(4,1)} \right) \right\},
\]

which will appear in a combination \(\sum_{b=1}^{3} q_b \alpha_b(\nu^-) \equiv q \cdot \alpha(\nu^-)\) below.

**Region 1:** 

\[
-\frac{2\hat{\mu}}{2q_1 + q_1 \Sigma_{\nu} - q_\alpha(\nu^-)} \leq x \leq \frac{2\hat{\mu}}{2q_1 - q_1 \Sigma_{\nu} + q_\alpha(\nu^-)} ; \\
\rho(x) = -\frac{32\hat{\mu} - 16q_\alpha(\nu^-)}{(\Sigma_{\nu} - 2)2(\Sigma_{\nu} + 2)} ; \\
y_a - y_{a+1} = \frac{2\hat{\mu}(\Sigma_{\nu} - 4\nu_{(a,a+1)}^-(1)) + x[q_3(\Sigma_{\nu} - 2)(\Sigma_{\nu} + 2) - q_\alpha(\nu^-)(\Sigma_{\nu} - 4\nu_{(a,a+1)}^-)]}{16\hat{\mu} - 8q_\alpha(\nu^-)} , \quad a = 1, 2, 3.
\]

**Region 2:** 

\[
-\frac{2\hat{\mu}}{2(q_1 + q_2 + q_3) - q_1 \Sigma_{\nu} - q_\alpha(\nu^-)} \leq x \leq \frac{2\hat{\mu}}{2q_1 + q_1 \Sigma_{\nu} - q_\alpha(\nu^-)} ; \\
\rho(x) = -\frac{24\hat{\mu} - 4q_1(\Sigma_{\nu} - 2)(3q_\alpha(\nu^-))}{(\Sigma_{\nu} - 2)(\Sigma_{\nu} + 1)} ; \\
y_1 - y_2 = \frac{1}{2} - \nu^{(1,2)}_{(1,2)} ; \\
y_a - y_{a+1} = \frac{2\hat{\mu}(2\Sigma_{\nu} - 6\nu_{(a,a+1)}^- - 1) + x[q_1(1 + 2\nu_{(a,a+1)}^-) + 2q_3(\Sigma_{\nu} + 1)(\Sigma_{\nu} - 2) - q_\alpha(\nu^-)(2\Sigma_{\nu} - 6\nu_{(a,a+1)}^- - 1)]}{24\hat{\mu} - 4q_1(\Sigma_{\nu} - 2)(12xq_\alpha(\nu^-))} , \quad a = 2, 3 ; \\
Y^{(1,2)}_{(1,2)} = -\frac{4\hat{\mu} + 2\pi x q_1(\Sigma_{\nu} + 2) - \nu \alpha(\nu^-)}{2\Sigma_{\nu} + 1} .
\]
Region 2+: \[ \frac{2\bar{\mu}}{q_1-q_1 \Sigma_\nu+q_\alpha(\nu^-)} \leq x \leq \frac{2\bar{\mu}}{2(q_1+q_2+q_3)+(q_1+q_2+q_3) \Sigma_\nu+q_\alpha(\nu^-)} \]

\[ \rho(x) = \frac{-2\bar{\mu}-4x[q_1(\Sigma_\nu+2)+3q_\alpha(\nu^-)]}{(\Sigma_\nu+2)(\Sigma_\nu+1)} \]

\[ y_1 - y_2 = -\nu(1,2) \]

\[ y_{a} - y_{a+1} = \frac{2\bar{\mu}(2\Sigma_\nu-6q_{(a+1)}+1)+x[(q_1+1+2q_{(2,3})]+2q_\alpha(\Sigma_\nu+2)+q_\alpha(\nu^-)]}{2\bar{\mu}-12\Sigma_\nu+12q_\alpha(\nu^-)}, \quad a = 2, 3; \]

\[ Y_{(1,2)}^+ = \frac{4\bar{\mu}+2x[q_1(\Sigma_\nu+2)-q_\alpha(\nu^-)]}{\Sigma_\nu+1}. \]

Region 3+: \[ \frac{2\bar{\mu}}{q_1+q_2+q_3 \Sigma_\nu+q_\alpha(\nu^-)} \leq x \leq \frac{2\bar{\mu}}{q_1+q_2+q_3 \Sigma_\nu+q_\alpha(\nu^-)} \]

\[ \rho(x) = \frac{-16\bar{\mu}-4x[2q_1+(q_2+q_3)(1+\Sigma_\nu)-2q_\alpha(\nu^-)]}{(\Sigma_\nu+1)(\Sigma_\nu+1)} \]

\[ y_1 - y_2 = \frac{1}{2} - \nu(1,2) \]

\[ y_{3} - y_{4} = -\nu(4,1); \]

\[ y_{(1,2)}^- = \frac{-4\bar{\mu}-2x[q_1(\Sigma_\nu+2)-q_\alpha(\nu^-)]}{\Sigma_\nu+1}, \quad Y_{(1,2)}^+ = \frac{4\bar{\mu}+2x[q_1+q_2+q_3 \Sigma_\nu+q_\alpha(\nu^-)]}{\Sigma_\nu+1}. \]

Region 4+: \[ \frac{2\bar{\mu}}{q_1+q_2+q_3 \Sigma_\nu+q_\alpha(\nu^-)} \leq x \leq \frac{2\bar{\mu}}{q_1+q_2+q_3 \Sigma_\nu+q_\alpha(\nu^-)} \]

\[ \rho(x) = \frac{-8\bar{\mu}-4x[q_1+q_2+q_3(1+\Sigma_\nu)-q_\alpha(\nu^-)]}{\Sigma_\nu+1} \]

\[ y_1 - y_2 = \frac{1}{2} - \nu(1,2) \]

\[ y_{3} - y_{4} = \nu(3,4); \]

\[ y_{(1,2)}^- = \frac{-4\bar{\mu}-2x[q_1(\Sigma_\nu+2)-q_\alpha(\nu^-)]}{\Sigma_\nu+1}, \quad Y_{(1,2)}^+ = \frac{4\bar{\mu}+2x[q_1+q_2+q_3(1+\Sigma_\nu)-q_\alpha(\nu^-)]}{\Sigma_\nu+1}. \]

Let us visualize all these expressions for \( \rho(x) \) and \( y(x) \)'s in Figure 4 using the numerical values: \( q_1 = 78, q_2 = 2, q_3 = -29 \) and all \( \Delta \)'s equal to \( \frac{1}{5} \). With the \( \rho(x) \) known in all the regions, we can just use the normalization condition \( \int dx \rho(x) = 1 \) to get \( \bar{\mu} \), which gives the Bethe potential \( \mathcal{V} \propto \bar{\mu} \). Next, we plot the divergent contributions in Figure 5, which are crucial to get the correct twisted index. Note that all the \( Y^\pm(x) \)'s are in the upper half plane as required by consistency.

Finally, we have to integrate the expression given in (2.22) with all the \( \{ \rho(x), y_{a,I}(x), Y^\pm_{(a,I,b,J)} \} \) obtained here in each region carefully. The result is a huge expression and unless we take the
help of index theorem, it is hard to make sense of it. Though, we can make sure that the integrated expression and the one obtained via the index theorem are identical, which we have done for both \( \hat{A}_2 \) and \( \hat{A}_3 \) to check that (2.19) does give the correct \( Y^\pm(x) \)'s. Thus, instead of writing the full expression for \( \hat{A}_3 \) here, we present the explicit general result for \( \hat{A}_m \) quiver directly.

4.2 \( \hat{A}_m \) Result

Having discussed the non-trivial case of \( \hat{A}_3 \) quiver of this class explicitly, we write down the generalization of (well-known) \( \hat{A}_1 \) and (above-mentioned) \( \hat{A}_3 \) results:

\[
\mathcal{V} = \frac{4\pi N^{3/2}}{3} \tilde{\mu} \quad \text{with} \quad \frac{1}{\tilde{\mu}^2} = 32 \sum_{a=1}^{m+1} \left[ \frac{|\gamma_{a,a+1}|}{\sigma_a \sigma_{a+1}} + \frac{|\gamma_{a,a+1}|}{\sigma_{a+m+1} \sigma_a \sigma_{a+2}} \right],
\]

(4.5)

where only the \( \sigma \)'s definitions slightly changes compared to (3.7)

\[
\sigma_a = \sum_{b=1}^{m+1} \left[ |\gamma_{a,b}| + 2\gamma_{b,a} \nu_{(b,b+1)} \right], \quad \sigma_{a+m+1} = \sum_{b=1}^{m+1} \left[ |\gamma_{a,b}| - 2\gamma_{b,a} \nu_{(b,b+1)} \right].
\]

(4.6)
Thus, we see that if we substitute $\Delta \to 2\nu$ in (3.6), we get for $\hat{A}$ quivers:

$$\frac{1}{\mu |2\nu|^2} = \frac{4\pi |3/2\nu|^3}{3 \hat{\mu}^3} \Rightarrow 4\mathcal{V}[\nu] = F_{S1}[2\nu]$$

(4.7)

as promised earlier.

The index is implicitly given by the relation (2.29) but massaging it a little bit, we can give an explicit expression in terms of $\hat{\mu}$ that facilitates checking with the expression given by the integral in (2.22):

$$\hat{I} = (g-1) \frac{4\pi N^{3/2}}{3} \hat{\mu}^3 \left[ \frac{4}{\mu^2} - \frac{1}{2} \sum_I (n_I - 2\nu_I) \frac{\partial \left( \frac{1}{\mu^2} \right)}{\partial \nu_I} \right].$$

(4.8)

The derivative term reads explicitly (after some tedious algebra) as follows:

$$\sum_I (n_I - \nu_I) \frac{\partial \left( \frac{1}{\mu^2} \right)}{\partial \nu_I} = -64 \sum_{a=1}^{m+1} [\gamma_{a,a+1} \left[ \frac{\sigma_a (f_{a+1}(n) - 2f_{a+1}(\nu))}{\sigma_a^2 \sigma_{a+1}^2} + \frac{\sigma_{a+m+1} (f_{a+m+2}(n) - 2f_{a+m+2}(\nu))}{\sigma_{a+m+1}^2 \sigma_{a+m+2}^2} \right]],$$

where $f_{a+m+1}(n) = (-) \sum_{b=1}^{m+1} 2\gamma_{b,a} n_{(b+1)}$, and similarly for $f_a(\nu)$.

Let us move on to the $\hat{D}$ quivers now with an explicit solution for $\hat{D}_4$ quiver first.

### 4.3 $\hat{D}_4$ Solved

We now move to $\hat{D}$ quivers and give the solution for $\hat{D}_4$ explicitly here. Given the scalings of Table 1, the boundary $x$-values, $\rho(x)$ and $y_{a,I}(x)$ follow straightforwardly from Section 3.2 so we do not repeat them here. Only the divergent contributions $Y^\pm(x)$’s are new and we enumerate them region-wise below (we again suppress the $I = 1$ index for $a = 1, \cdots, 4$ and $J = 2$ for $b = 5$).

**Region 1:** $\frac{2\hat{\mu}}{2(p_1+p_2)-2p_\alpha(\nu^-)} \leq x \leq \frac{2\hat{\mu}}{2(p_1+p_2)+2p_\alpha(\nu^-)}$

No $Y^\pm(x)$’s yet.

**Region 2−:** $\frac{2\hat{\mu}}{2p_1-2p_\alpha(\nu^-)} \leq x \leq -\frac{2\hat{\mu}}{2(p_1+p_2)-2p_\alpha(\nu^-)}$

$$Y^-(1;5) = -4\pi \left( \hat{\mu} + x(p_1 + p_2) - xp \cdot \alpha(\nu^-) \right).$$

**Region 2+:** $\frac{2\hat{\mu}}{2(p_1+p_2)+2p_\alpha(\nu^-)} \leq x \leq \frac{2\hat{\mu}}{2p_1+2p_\alpha(\nu^-)}$

$$Y^+(1;5) = -4\pi \left( \hat{\mu} - x(p_1 + p_2) - xp \cdot \alpha(\nu^-) \right).$$

21
Region 3−: \( -\frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4-2p\alpha(\nu^-)} \leq x \leq -\frac{2\tilde{\mu}}{2p_1-2p\alpha(\nu^-)} \)

\[ Y^-_{(1;5)} = -4\pi \left( \tilde{\mu} + x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^+_{(2;5)} = -4\pi \left( \tilde{\mu} + xp_1 - xp\cdot\alpha(\nu^-) \right). \]

Region 3+: \( \frac{2\tilde{\mu}}{2p_1+2p\alpha(\nu^-)} \leq x \leq \frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4+2p\alpha(\nu^-)} \)

\[ Y^+_{(1;5)} = -4\pi \left( \tilde{\mu} - x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^-_{(2;5)} = -4\pi \left( \tilde{\mu} - xp_1 - xp\cdot\alpha(\nu^-) \right). \]

Region 4−: \( -\frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4-2p\alpha(\nu^-)} \leq x \leq -\frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4-2p\alpha(\nu^-)} \)

\[ Y^-_{(1;5)} = -4\pi \left( \tilde{\mu} + x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^+_{(2;5)} = -4\pi \left( \tilde{\mu} + xp_1 - xp\cdot\alpha(\nu^-) \right), \]

\[ Y^+_{(4;5)} = -2\pi \left( 2\tilde{\mu} + x(p_1 + p_2 + p_3 + p_4) - 2xp\cdot\alpha(\nu^-) \right). \]

Region 4+: \( \frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4+2p\alpha(\nu^-)} \leq x \leq \frac{2\tilde{\mu}}{p_1+p_2+p_3+p_4+2p\alpha(\nu^-)} \)

\[ Y^+_{(1;5)} = -4\pi \left( \tilde{\mu} - x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^-_{(2;5)} = -4\pi \left( \tilde{\mu} - xp_1 - xp\cdot\alpha(\nu^-) \right), \]

\[ Y^+_{(4;5)} = -2\pi \left( 2\tilde{\mu} - x(p_1 + p_2 + p_3 + p_4) - 2xp\cdot\alpha(\nu^-) \right). \]

Region 5−: \( -\frac{2\tilde{\mu}}{p_1+p_2-2p\alpha(\nu^-)} \leq x \leq -\frac{2\tilde{\mu}}{p_1+p_2-2p\alpha(\nu^-)} \)

\[ Y^-_{(1;5)} = -4\pi \left( \tilde{\mu} + x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^+_{(2;5)} = -4\pi \left( \tilde{\mu} + xp_1 - xp\cdot\alpha(\nu^-) \right), \]

\[ Y^+_{(3;5)} = -2\pi \left( 2\tilde{\mu} + x(p_1 + p_2 + p_3 - p_4) - 2xp\cdot\alpha(\nu^-) \right), \]

\[ Y^+_{(4;5)} = -2\pi \left( 2\tilde{\mu} + x(p_1 + p_2 + p_3 + p_4) - 2xp\cdot\alpha(\nu^-) \right). \]

Region 5+: \( \frac{2\tilde{\mu}}{p_1+p_2+p_3-p_4+2p\alpha(\nu^-)} \leq x \leq \frac{2\tilde{\mu}}{p_1+p_2+2p\alpha(\nu^-)} \)

\[ Y^+_{(1;5)} = -4\pi \left( \tilde{\mu} - x(p_1 + p_2) - xp\cdot\alpha(\nu^-) \right), \quad Y^-_{(2;5)} = -4\pi \left( \tilde{\mu} - xp_1 - xp\cdot\alpha(\nu^-) \right), \]

\[ Y^-_{(3;5)} = -2\pi \left( 2\tilde{\mu} - x(p_1 + p_2 + p_3 - p_4) - 2xp\cdot\alpha(\nu^-) \right), \]

\[ Y^-_{(4;5)} = -2\pi \left( 2\tilde{\mu} - x(p_1 + p_2 + p_3 + p_4) - 2xp\cdot\alpha(\nu^-) \right). \]

Let us again visualize all these expressions for \( Y^\pm(x) \)'s in Figure 6 using the numerical values: \( p_1 = 15, \ p_2 = 8, \ p_3 = 4, \ p_4 = 1 \) and all \( \nu \)'s equal to \( \frac{1}{4} \). We see that all the \( Y^\pm(x) \)'s are in the upper half plane as expected. Finally, we integrate the expression given in (2.22) by substituting the \( \{ \rho(x), y_{a,f}(x), Y^\pm_{(a,f,b,J)} \} \) in each region carefully. The result is again a huge expression and we take help of the index theorem to write it concisely. Before we do that, a comment for evaluation of (2.22) for \( \tilde{D}_n \) with \( n > 4 \) is in order, after which, we will directly present the explicit general result for \( \tilde{D}_n \) quiver.

**Comment.** Note that the \( Y^\pm(x) \)-functions of \( \tilde{D}_4 \) are same in all the regions and no discontinuity appears unlike the case of \( \tilde{A}_3 \). This might lead one to think that all \( \tilde{D} \) quivers exhibit such a simple behaviour but this is a highly misleading behaviour of \( \tilde{D}_4 \) and doesn’t generalize any further. A true general behaviour appears with \( \tilde{D}_5 \) with discontinuities and subtleties, which almost break down the algebraic system of equations (2.19) used to solve for \( Y^\pm(x) \)'s.
This happens because (assuming similar order of $p$’s and similar progression of regions) one of the original inequalities, say, $0 < y_{2,1} - y_{5,1} + \nu_{(2,5)} < 1$ can change to (a subset of) an already existing inequality, say, $-\frac{1}{2} < y_{5,1} - y_{6,2} - \nu_{(6,5)} < 0$ in some region (via saturation sequence like $y_{2,1} \to y_{5,2} \to y_{6,2}$) and when saturation occurs $y_{5,1} - y_{6,2} - \nu_{(6,5)} = 0$ in some later region, we will have one more $Y^{\pm}(x)$’s to solve than there are equations in (2.19)! This problem is solved by choosing the two relevant $Y^{\pm}(x)$’s ($Y^{-(2,1;5),1}_{(2,1;5),1}$ and $Y^{+(5,1;6),2}_{(5,1;6),2}$ in above scenario) to be the same. Thus, the earlier algorithm needs to be modified by augmenting (2.19) with extra equality constraints among $Y^{\pm}(x)$’s that appear due to saturation of multiple original inequalities. We have used this modified algorithm for solving $\hat{D}_5$ and $\hat{D}_6$ matrix models and checked that the twisted index obtained from the integral expression (2.22) and that obtained via the index theorem (2.29) are identical.

4.4 $\hat{D}_n$ Result

It should be no surprise, after calculational dust settles, that the result for $\hat{D}$ quivers will look similar to that for $\hat{A}$ quivers:

$$\mathcal{V} = \frac{4\pi N^{3/2}}{3}\tilde{\mu} \quad \text{with} \quad \frac{1}{\tilde{\mu}^2} = 32 \sum_{a=0}^{n} \left[ \frac{|\gamma_{a,a+1}|}{\sigma^+_a \sigma^+_a} + \frac{|\gamma_{a,a+1}|}{\sigma^-_a \sigma^-_a} \right], \quad (4.9)$$

where only the $\sigma$’s definitions slightly changes compared to (3.16)

$$\tilde{\sigma}_a^\pm = \sum_{b=1}^{n} \left[ |\gamma_{a,b}| + |\gamma_{a,-b}| \pm 2(\gamma_{a,b} - \gamma_{a,-b})\alpha_b(\nu^-) \right] - 4|\gamma_{a,n+1}|. \quad (4.10)$$

Thus, we again see that upon substituting $\Delta \to 2\nu$ in (3.15), we get for $\hat{D}$ quivers

$$\frac{1}{\mu[2\nu]^2} = \frac{1}{16\tilde{\mu}[\nu]^2} \quad \Rightarrow \quad 4\mathcal{V}[\nu] = F_{S^3}[2\nu] \quad (4.11)$$

as expected.
The index can again be written explicitly as follows:

$$\mathcal{I} = (g - 1)\frac{4\pi N^{3/2}}{3} \left[ \frac{4}{\mu^2} - \frac{1}{2} \sum_I (n_I - 2\nu_I) \frac{\partial (\frac{1}{\mu^2})}{\partial \nu_I} \right] \mu^3; \quad (4.12)$$

$$\sum_I (n_I - 2\nu_I) \frac{\partial (\frac{1}{\mu^2})}{\partial \nu_I} = -64 \left( f(n) - 2f(\nu) \right) \left( \frac{|\gamma_{-1,1}| (\bar{\sigma}^+_1 + \bar{\sigma}^+_1)}{(|\bar{\sigma}^-_1|)^2 (|\bar{\sigma}^-_1|)^2} + \sum_{\pm,a=1}^{n} \frac{|\gamma_{a,a+1}| (\bar{\sigma}^+_a + \bar{\sigma}^+_a)}{(\bar{\sigma}^-_a)^2 (\bar{\sigma}^-_a+1)} \right),$$

where $f(n) = \sum_{b=1}^{n} 2(\gamma_{a,b} - \gamma_{a,-b})a_b(n)$, and similarly for $f(\nu)$. Due to the fact that $(\gamma_{a,b} - \gamma_{a,-b}) = 2\beta_b$ does not depend on the subscript $a$, these $f(\cdot)$’s become an overall factor and the explicit expression for $\hat{D}$ quiver index simplifies considerably compared to the analogous expression for $\hat{A}$ quivers.

5 Summary and Outlook

This paper contains two interconnected results:

**Volume:** We computed the explicit free energy $F_{S^3}$ for $\hat{D}$ quivers in terms of the R-charges $\Delta_{(a,b)}$ of the bifundamentals, obtained by combining (2.9) and (3.15). According to AdS/CFT correspondence, the formula (3.15) provides a prediction for the volumes of certain Sasaki-Einstein 7-manifolds $Y_7$, which describe the $AdS_4 \times Y_7$ M-theory duals.

**Entropy:** We computed the explicit twisted index $\mathcal{I}$ for $\hat{A}D$ quivers, (4.8) and (4.12), in terms of the chemical potentials $\nu_{(a,b)}$ and flavour fluxes $n_{(a,b)}$. We expect that the extremization of these formulas with respect to $\nu$’s leading to the expression $\mathcal{I}(\nu, n)$ reproduces the macroscopic entropy of the dual black hole solutions in the 4d gauged supergravity uplifted to M-theory with the above-mentioned $Y_7$’s. In the simplifying case of universal twist, the extremization procedure is automatic, leading to $n_I = 2\nu_I$ and $S_{BH} = \mathcal{I} = (g - 1)F_{S^3}$ follows via the index theorem (2.29) for $\hat{A}D$ quivers as shown in [32,33].

Along the way, we computed the large $N$ limit of the partition functions for 3d $\mathcal{N} = 2$ quiver theories on $S^3$ and $\Sigma_3 \times S^1$ involving bifundamental and fundamental matters. We obtained constraints on relevant parameters ($\Delta$ for $F_{S^3}$ and $\{\nu, n\}$ for $\mathcal{I}$) under the requirement that the resulting matrix model be local, leading to a large class of CSm quiver theories including the $\hat{A}D$ quivers. The fundamental matters contribute in a trivial way and that contribution can be included in the results presented here following [34,35]. An intermediate construction to obtain the twisted index is that of the Bethe potential $\mathcal{V}$, which we find is related to the free energy via $F_{S^3}[2\nu] = 4\mathcal{V}[\nu]$. It was shown in [26] that for $\hat{A}$ quivers and related theories, this relation is true off-shell too but with a *different* numerical factor. We extended this result to $\hat{D}$ quivers and proved that the relation holds true in all the integration regions with the *same* numerical factor of 4.

We note that one could study these theories on more general Seifert manifolds as discussed in [37–39]. The $\mathcal{M}_{g,p}$ manifolds include both the manifolds studied here as in $\mathcal{M}_{0,1} = S^3$ and $\mathcal{M}_{g,0} = \Sigma_g \times S^1$. In this framework, the observation $4\mathcal{V}[\nu] = F_{S^3}[2\nu]$ in the present context may be easily explained following the logic of [38]. In addition, it should be possible to generalize the results presented here straightforwardly to these manifolds.

An Elephant in the room is the fact that expressions for free energies of $\hat{E}_{6,7,8}$ are missing in this paper. As is well-known, even in the $\mathcal{N} = 3$ case [34] the known expressions are valid only
for a subset of CS levels. An all-encompassing formula in terms of roots or graphs as in the case of \( \hat{AD} \) quivers is not known for them. So we refrained from giving the \( \mathcal{N} = 2 \) extensions of the \( \mathcal{N} = 3 \) formulas but comment that it would be much more interesting to figure out the fully general volume formula for \( \hat{E} \) quivers. The Fermi-gas formalism \([40–43]\) could be a helpful tool in this quest, given that the polygon formula appears naturally as a Fermi surface in this formalism.

Finally, it goes without saying that computing volumes of the Sasaki-Einstein 7-manifolds explicitly and constructing explicit M-theory duals for \( \hat{ADE} \) quivers with non-universal flavour fluxes would be an interesting exercise to test the AdS/CFT correspondence.

**Acknowledgements**

DJ thanks P. M. Crichigno for comments, corrections and suggestions on the draft of this paper. AR is indebted to Arnab Kundu for various discussions related to this work specifically and to physics in general. He acknowledges support from the Department of Atomic Energy, Government of India.

We also acknowledge that most of this work would not have been possible without Mathematica v11.3 \([44]\).

**A Derivations and Proofs**

We collect here some details of the calculations that went into evaluating free energy and twisted index of the CS quiver gauge theories. Our derivations have considerable overlap with \([10,38]\) than with \([24,26]\).

\( F_{S^3} \)

We start with the expression whose large \( N \) limit is to be obtained:

\[
F_{S^3} \approx -i\pi N \int dx \rho(x) \sum_{a,I} k_a \left( N^\alpha x + iy_{a,I}(x) \right)^2
- N^2 \int dx dx' \rho(x) \rho(x') \sum_{a,I,J} \log \left| 2 \sinh \left( \pi N^\alpha (x - x') + i\pi (y_{a,I}(x) - y_{a,J}(x')) \right) \right|
- N^2 \int dx dx' \rho(x) \rho(x') \sum_{(a,b) \in \mathcal{E}, I,J} \ell \left( 1 - \Delta_{(a,b)} + iN^\alpha (x - x') - (y_{a,I}(x) - y_{b,J}(x')) \right)
- N \int dx \rho(x) \sum_{a,(f^a)_I} \ell \left( 1 - \Delta_{f^a} + iN^\alpha x - y_{a,I} \right) - N \int dx \rho(x) \sum_{a,(\bar{f}^a)_I} \ell \left( 1 - \bar{\Delta}_{f^a} - iN^\alpha x + y_{a,I} \right).
\]

The four lines correspond to four different contributions as follows:
Chern-Simons. This is pretty straightforward

\[-i\pi N \int dx \rho(x) \sum_{a,l} k_a (N^{\alpha} x_a^2 + 2i N^{\alpha} x_ya, l(x) - y_{a,l}(x))^2 \]

\[= -i\pi N^{1+2\alpha} \int dx \rho(x) \sum_{a} (n_a k_a x_a^2 + 2\pi N^{1+\alpha} \int dx \rho(x) x \sum_{a,l} k_{a} y_{a,l}(x) + \mathcal{O}(N), \quad (A.1) \]

and we get the first line of equation (2.7).

Vectors. This is again straightforward following [14]. We change variables \(\pi N^{\alpha} (x - x') \rightarrow \xi\) which implies to leading order \(\rho(x') \rightarrow \rho(x)\) and \(y(x') \rightarrow y(x)\) so we get:

\[-\frac{N^{2-\alpha}}{\pi} \int dx \rho(x)^2 \int_{-M}^{M} d\xi \sum_{a,l,j} \log [2 \sinh (|\xi| + i\pi \sgn(\xi) \delta_{y_{a,l,j}}(x))] \]

\[= -\frac{N^{2-\alpha}}{\pi} \int dx \rho(x)^2 \left[ \sum_{a} n_a \frac{(M^{2} + \frac{\pi^{2}}{12})}{\delta} - \sum_{a,l,j} \frac{1}{4} \arg \left( e^{2\pi i \delta_{y_{a,l,j}}(x)^{-1/2}} \right)^{2} \right]. \quad (A.2)\]

The \(\arg()\) term appears in second line of (2.7) and requiring the value of exponent to lie in the principal branch (i.e., \(-\frac{1}{2} < \delta_{y_{a,l,j}} \rightarrow \frac{1}{2} \leq \frac{1}{2}\)) gives the relevant inequality of (3.1). Now we show that the divergent \(\mathcal{O}(M^{2})\) (and a finite \(\mathcal{O}(1)\)) piece cancels a similar term coming from matter contributions.

(Anti-)Bifundamentals. This is slightly tricky but assuming equal number of bifundamental and anti-bifundamental matter at each edge initiates a few cancellations. Following through a direct calculation (refer to [10] for a slightly different derivation) with a similar change of variables \(N^{\alpha} (x - x') \rightarrow \xi\) as above and defining \(\mathcal{P}_{(a,b)} = 1 - \Delta_{(a,b)} - \delta_{y_{a,b,1,j}}(x), \mathcal{P}_{(b,a)} = 1 - \Delta_{(b,a)} + \delta_{y_{a,b,1,j}}(x)\), we get (using the definition (2.2) of \(\ell(z)\)):

\[-N^{2-\alpha} \int dx \rho(x)^2 \int_{-M}^{M} d\xi \sum_{(a,b) \in E} \sum_{l,j} \left( \ell(\mathcal{P}_{(a,b)} + i\xi) + \ell(\mathcal{P}_{(b,a)} - i\xi) \right) \]

\[= -N^{2-\alpha} \int dx \rho(x)^2 \sum_{(a,b) \in E} \sum_{l,j} \left( \frac{-i}{3} M^{3} + \frac{i}{6} M^{2} \left( -1 + 6 \mathcal{P}_{(a,b)}^{2} \right) \right) + \left( \mathcal{P}_{(a,b)} \rightarrow \mathcal{P}_{(b,a)} \right). \quad (A.3)\]

Following identities are required for polylogs when \(M \rightarrow +\infty\) and \(a \in \mathbb{R}\) to simplify the above expressions:

\[\text{Li}_1 \left( e^{M + 2\pi i a} \right) \rightarrow -M - i \arg \left( e^{2\pi i (a + 1/2)} \right) \quad (A.4)\]

\[\text{Li}_2 \left( e^{M + 2\pi i a} \right) \rightarrow \frac{M^{2}}{2} - i M \arg \left( e^{2\pi i (a + 1/2)} \right) - \left( \frac{\pi^{2}}{6} - \frac{1}{2} \arg \left( e^{2\pi i (a + 1/2)} \right)^{2} \right) \quad (A.5)\]

\[\text{Li}_3 \left( e^{M + 2\pi i a} \right) \rightarrow \frac{M^{3}}{6} - \frac{i}{2} M^{2} \arg \left( e^{2\pi i (a + 1/2)} \right) - M \left( \frac{\pi^{2}}{6} - \frac{1}{2} \arg \left( e^{2\pi i (a + 1/2)} \right)^{2} \right) \]

\[- \frac{i}{6} \arg \left( e^{2\pi i (a + 1/2)} \right) \left( \pi^{2} - \arg \left( e^{2\pi i (a + 1/2)} \right)^{2} \right). \quad (A.6)\]
The term at $\mathcal{O}(M^3)$ simply cancels without the need to add $\mathcal{P}_{(a,b)}$ and $\mathcal{P}_{(b,a)}$ contributions. Upon adding both contributions\footnote{We also scaled $M \to \frac{M}{\pi}$ to match the transcendentality of other terms and to compare with (A.2).}, we get the following terms at various orders of $M$ (suppressing $\int dx \rho(x)^2$):

\[
\mathcal{O}(M^2) : - \frac{N^{2-\alpha}}{\pi} \sum_{(a,b) \in E} n_a n_b \left( -2 + \Delta_{(a,b)} + \Delta_{(b,a)} \right) ; \\
\mathcal{O}(M) : \frac{iN^{2-\alpha}}{4\pi^2} \sum_{(a,b) \in E} \sum_{I,J} \left( \pi^2(1 - 4P_{(a,b)}^2) + \arg(\cdots)(4\pi P_{(a,b)} - \arg(\cdots)) \right) + (\mathcal{P}_{(a,b)} \to \mathcal{P}_{(b,a)}) ; \\
\mathcal{O}(1) : - \frac{N^{2-\alpha}}{\pi} \sum_{(a,b) \in E} n_a n_b \frac{\pi^2}{12} \left( -2 + \Delta_{(a,b)} + \Delta_{(b,a)} \right) - \frac{N^{2-\alpha}}{4\pi} \sum_{(a,b) \in E} \sum_{I,J} \left( \mathcal{P}_{(a,b)} \arg(\cdots)^2 \\
+ \frac{1}{3\pi} \arg(\cdots) \left( \pi^2 - \arg(\cdots)^2 \right) \right) + (\mathcal{P}_{(a,b)} \to \mathcal{P}_{(b,a)}) ,
\]

where $\cdots \equiv e^{2\pi i(\mathcal{P}_{(a,b)} + \frac{1}{2})}$. The $\mathcal{O}(M^2)$ term from (A.2) and (A.7) add up to give the $\tilde{\text{ADE}}$ constraint (2.6) that was derived from the saddle point equation in the main text. This kills the $\mathcal{O}(M^2)$ as well as one of the $\mathcal{O}(1)$ contributions from vector and (anti-)bifundamental matter multiplets. Again, requiring the exponent inside $\arg(\cdots)$ to lie in the principal branch gives the relevant inequalities of (3.1). Effectively, we have to impose $0 \leq \delta y_{ab,IJ} + \Delta_{(a,b)} < 1$ and $-1 < \bar{\delta} y_{ab,IJ} - \Delta_{(b,a)} \leq 0$ (the equalities denote the saturation values at region boundaries) which lead to the $\mathcal{O}(M)$ contribution (A.8) vanishing identically. The remaining $\mathcal{O}(1)$ contribution from (A.9) is what appears in the third and fourth lines of (2.7).

\textbf{(Anti-)Fundamentals}. This contribution follows directly from the definition of the $\ell(z)$-function after using the polylog identities given above:

\[
- N \int dx \rho(x) \sum_{a, \{f^a\}, I} \left( -\frac{i}{2} N^{2\alpha} \pi x^2 - N^\alpha \pi \left| x \right| \left( 1 - \Delta_f - y_{a,I}(x) \right) + \mathcal{O}(1) \right) \\
- N \int dx \rho(x) \sum_{a, \{f^a\}, I} \left( \frac{i}{2} N^{2\alpha} \pi x^2 - N^\alpha \pi \left| x \right| \left( 1 - \tilde{\Delta}_f + y_{a,I}(x) \right) + \mathcal{O}(1) \right),
\]

which is what appears in the last two lines of (2.7).
Again, starting with the expression whose large $N$ limit is to be obtained:

\[
\mathcal{V} = -i \sum_{a,i} \pi k_a (u_i^a)^2 + \frac{1}{2} \sum_{a,i,j} \pi \text{sgn}(j-i)(u_i^a - u_j^a) - i \sum_{(a,b) \in E} \sum_{i,j} (v(u_i^a - u_j^b + i\nu_{(a,b)})
\]

\[
+ v(u_j^b - u_i^a + i\nu_{(b,a)}) - i \sum_{a,i} \sum_{\{f^a\}} v(u_i^a + i\nu_{f^a}) - i \sum_{a,i} \sum_{\{f^a\}} v(-u_i^a + i\nu_{f^a})
\]

\[
\mathcal{V} \approx -i\pi N \int dx \rho(x) \sum_{a,I} k_a (N^\alpha x + iy_{a,I}(x))^2
\]

\[
+ \frac{\pi}{2} N^2 \int dx dx' \rho(x) \rho(x') \sum_{a,I,J} \text{sgn}(x' - x) \big( N^\alpha (x - x') + i\delta_{y_{a,I}(x)} \big)
\]

\[
- iN^2 \int dx dx' \rho(x) \rho(x') \sum_{(a,b) \in E} \big( v(N^\alpha (x - x') + i(\delta_{y_{ab,I}(x)} + \nu_{(a,b)})) + (\nu_{(b,a)} \text{ term}) \big)
\]

\[
- iN \int dx \rho(x) \sum_{a,I} v(N^\alpha x + i(y_{a,I}(x) + \nu_{f^a})) - iN \int dx \rho(x) \sum_{a,I} v(-N^\alpha x - i(\cdots))
\]

The four lines above correspond to different contributions as follows:

**Chern-Simons.** This is straightforward to compute and after imposing $n_a k_a = 0$ leads to just one term at leading order:

\[
\pi N^{1+\alpha} \int dx \rho(x) 2z \sum_{a,I} k_a y_{a,I}(x), \quad (A.11)
\]

which appears as the first term in (2.17).

**Vectors.** This integral is to be done using the same transformation ($N^\alpha (x - x') \to \xi$) as was done in the case of $F_{33}$ which gives us:

\[
\frac{\pi}{2} N^{2-\alpha} \int dx \rho(x)^2 \int^M_{-M} d\xi \sum_{a,I,J} \text{sgn}(-\xi) (\xi + i\delta_{y_{a,IJ}(x)}) = -\frac{\pi}{2} N^{2-\alpha} M^2 \sum_a \sum_{a,I,J} \int dx \rho(x)^2,
\]

(A.12)

which is clearly divergent but we expect this to be cancelled by the bifundamental matter contributions as we show next.

**(Anti-)Bifundamentals.** As done in the $F_{33}$ case, we change variables $N^\alpha (x - x') \to \xi$ and define $P_{(a,b)} = \delta_{y_{ab,IJ}(x)} + \nu_{(a,b)}$, $P_{(b,a)} = -\delta_{y_{ab,IJ}(x)} + \nu_{(b,a)}$ to get (using the definition (2.14) of $v(z)$):

\[
- iN^{2-\alpha} \int dx \rho(x)^2 \int^M_{-M} d\xi \sum_{(a,b) \in E} \sum_{I,J} \left( v(\xi + iP_{(a,b)}) + v(-\xi + iP_{(b,a)}) \right)
\]

\[
= - iN^{2-\alpha} \int dx \rho(x)^2 \sum_{(a,b) \in E} \sum_{I,J} \left( \frac{\pi}{3} M^3 - \frac{\pi}{6} M \left( 1 + 6P^2_{(a,b)} \right) \right) + \left( P_{(a,b)} \to P_{(b,a)} \right). \quad (A.13)
\]
Again, the term at $\mathcal{O}(M^3)$ simply cancels after using the polylog identities and we get the following terms at various orders of $M$ (suppressing $\int dx \rho(x)^2$):

\[
\mathcal{O}(M^2) : - N^{2-\alpha}\pi \sum_{(a,b) \in E} n_a n_b \left( -1 + \nu_{(a,b)} + \nu_{(b,a)} \right); \tag{A.14}
\]
\[
\mathcal{O}(M) : \frac{iN^{2-\alpha}}{4\pi} \sum_{(a,b) \in E} \sum_{I,J} \left( \pi^2 (1 + 4P_{(a,b)}^2) + \arg(\cdots)^2 \right) + \left( P_{(a,b)} \rightarrow P_{(b,a)} \right); \tag{A.15}
\]
\[
\mathcal{O}(1) : - \frac{N^{2-\alpha}}{24\pi^2} \sum_{(a,b) \in E} \sum_{I,J} \left( \arg(\cdots) \left( \pi^2 - \arg(\cdots)^2 \right) \right) + \left( P_{(a,b)} \rightarrow P_{(b,a)} \right), \tag{A.16}
\]

where $\cdots \equiv e^{2\pi i(P_{(a,b)} + 1/\alpha)}$. The $\mathcal{O}(M^2)$ term from (A.12) and (A.14) can be cancelled now leading to the $\hat{A}DE$ constraint of (2.16). The $\mathcal{O}(M)$ term leads to an imaginary constant in $\mathcal{V}$ which doesn’t affect the BAEs so we ignore it. The $\mathcal{O}(1)$ contribution in (A.16) is what appears in (2.17).

(Anti-)Fundamentals. This contribution follows directly from the definition of the $\nu(z)$-function after using the polylog identities as done in the case of $F_{S^0}$:

\[
- iN \int dx \rho(x) \sum_{a,\{f^a\},I} \left( - \frac{1}{2} N^{2\alpha} \pi x^2 - iN^{\alpha} \pi |x| \left( -1 + y_{a,I}(x) + \nu_{f^a} \right) + \mathcal{O}(1) \right) - iN \int dx \rho(x) \sum_{a,\{f^a\},J} \left( \frac{1}{2} N^{2\alpha} \pi x^2 + iN^{\alpha} \pi |x| \left( y_{a,J}(x) - \bar{\nu}_{f^a} \right) + \mathcal{O}(1) \right). \tag{A.17}
\]

After using the simplifying condition $f^a = \bar{f}^a$, $x^2$ and $y(x)$ terms above cancel and we get $(n_F - \nu_F)$ term of (2.17).

‘Homogeneous’ $\mathcal{V}$. $\mathcal{V}$ as written in the main text is not homogeneous with respect to $\nu$’s so first of all, we make $\mathcal{V}$ scale with $\nu$’s (at the very least) by defining new shifted $\nu$’s or multiplying $2\nu^+$ to $\gamma_{a,b}$ terms in $\bar{\sigma}$’s. Next, let us look at the on-shell expression for Bethe potential of $\hat{D}_4$ quiver and combine terms over a common denominator. We find that the highest power of $\nu$ that survives (after a few simplifications) in the numerator is 6 whereas that in the denominator is 10. The difference between them is of course $-4$. Now, looking at the general expression for $\mathcal{V}$ in (4.9), we note that a pair of terms with $\bar{\sigma}_5$ get included when moving up to $\hat{D}_5$, which changes the degree of both numerator and denominator by 2 so the difference still continues to be $-4$. Thus, by induction, we get that the highest power of $\nu$ in the numerator of $\mathcal{V}$ for $\hat{D}_n$ is $2(n-1)$ whereas that in the denominator is $2(n+1)$. The difference between them is of course $-4$ meaning that $\frac{1}{\nu^2}$ is of degree $-4$, which translates to the fact that $\mathcal{V} \propto \mu$ is of degree 2 as used in the main text. The same counting works for $\hat{A}$ quivers (starting with $\hat{A}_1$ which has $\mathcal{V}$ of obvious degree $-4$) and should work out for $\hat{E}$ quivers too.
\( I \)

The expression to be massaged at large \( N \) is obtained from (2.11) (up to a factor of \((g - 1)\)):

\[
I = \sum_{a,i,j \neq i} v'(u^i_a - u^j_a) + \sum_{(a,b) \in E} \sum_{i,j} \left( (n_{(a,b)} - 1) v'(u^i_a - u^j_b + i\nu_{(a,b)}) + (n_{(b,a)} - 1) \times v'(u^i_b - u^j_a + i\nu_{(b,a)}) \right) + \sum_{a, \{f^a\}, i} (n_{f^a} - 1) v'(u^i_a + i\nu_{f^a}) + \sum_{a, \{f^a\}, i} (\bar{n}_{f^a} - 1) v'(-u^i_a + i\bar{\nu}_{f^a}) + \log \mathcal{B}
\]

\[
I \approx N^2 \int dx dx' \rho(x) \rho(x') \sum_{a,I} v'(\sqrt{N}(x - x') + i\delta y_{a,I}(x))
\]

\[
+ N^2 \int dx dx' \rho(x) \rho(x') \sum_{(a,b) \in E} \sum_{I,J} \left( (n_{(a,b)} - 1) v'(\sqrt{N}(x - x') + i\mathcal{P}_{(a,b)}) + (n_{(b,a)} \text{ term}) \right)
\]

\[
+ N \int dx \rho(x) \sum_{(a,f^a), I} (n_{f^a} - 1) v'(\sqrt{N}x + i(y_{a,I}(x) + \nu_{f^a})) + N \int dx \rho(x) \sum_{a, \{f^a\}, I} (\bar{n}_{f^a} - 1) v'(\cdots)
\]

\[
+ N \int dx \rho(x) \left[ \mathcal{O}(\sqrt{N}) \text{ term from log } \mathcal{B} \right].
\]

As before, we work out serially each of the four lines above corresponding to different contributions as follows:

**Vectors.** The function \( v'(\alpha(u)) \) appears as the vector contribution because \( \prod_{\alpha} e^{\pi \alpha(u)} = 1 \). Using the polylog identities, we simply get:

\[
- N^{3/2} \frac{1}{2\pi} \int dx \rho(x)^2 \left[ \sum_a n_a^2 \left( \frac{M^2}{2} + \frac{\pi^2}{6} \right) - \sum_{a,I,j} \frac{1}{2} \arg \left( e^{2\pi i(\delta y_{a,I}(x) - 1/2)} \right)^2 \right]. \tag{A.18}
\]

The \( \arg() \) term appears in (2.22) and again the rest of the terms will cancel the next contribution.\(^\text{17}\)

**(Anti-)Bifundamentals.** The evaluation of this term is same as above and we get:

\[
- N^{3/2} \frac{1}{2\pi} \int dx \rho(x)^2 \sum_{(a,b) \in E} \left\{ (n_{(a,b)} - 1) \left[ n_a n_b \left( \frac{M^2}{2} + \frac{\pi^2}{6} \right) - \sum_{I,J} \frac{1}{2} \arg \left( e^{2\pi i(\delta y_{a,b,I}(x) + \nu_{(a,b)} - 1/2)} \right)^2 \right] \right\}
\]

\[
+ (n_{(b,a)} - 1) \left[ n_a n_b \left( \frac{M^2}{2} + \frac{\pi^2}{6} \right) - \sum_{I,J} \frac{1}{2} \arg \left( e^{2\pi i(-\delta y_{a,b,I}(x) + \nu_{(b,a)} - 1/2)} \right)^2 \right] \right\}. \tag{A.19}
\]

We see that the \( \mathcal{O}(M^2) \) (and the \( \frac{\pi^2}{6} \)) term cancels between the above expression and (A.18) if

\[
\sum_a n_a^2 + \sum_{(a,b) \in E} (n_{(a,b)} + n_{(b,a)} - 2) n_a n_b = 0, \tag{A.20}
\]

\(^\text{17}\)We do not explicitly write the imaginary \( \mathcal{O}(M) \) terms but one can check that using \( \Sigma_{a,I,J} \delta y_{a,I}(x) = 0 \), \( y(x) \)-dependence does not survive and using the \( ADE \) constraint, constant pieces cancel between vector and bifundamental contributions, just like the \( \left( \frac{M^2}{2} + \frac{\pi^2}{6} \right) \) terms.
which is same as (2.21), leading to the $\hat{A}D\bar{E}$ constraint when $n_{(a,b)} + n_{(b,a)} = 1$ as mentioned in the main text. The remaining arg() terms upon imposing the constraint on $\nu$’s and $n$’s gives the finite bifundamental contributions to (2.22).

In addition, there are contributions from bifundamentals when $\nu'(z)$ diverges at $z = 0$, which are called tail contributions in the literature. This happens when $x = x'$ and $\delta y_{ab,IJ}(x) + \nu_{(a,b)} = 0$ or $\delta y_{ab,IJ}(x) - \nu_{(b,a)} = 0$. Thus, following the analysis around (2.19), we can write for the divergent bifundamental contributions to $\mathcal{I}$ (for specific $a, b, I, J$ values):

$$
\delta y_{ab,IJ}(x) + \nu_{(a,b)} = 0 : -N \int dx \rho(x)n_{(b,a)}\nu'(e^{-N^{1/2}Y^+_{(a,b,I,J)}(x)}) \approx -N^{3/2} \int dx \rho(x)n_{(b,a)}Y^+_{(a,b,I,J)}(x)
$$

$$
\delta y_{ab,IJ}(x) - \nu_{(b,a)} = 0 : -N \int dx \rho(x)n_{(a,b)}\nu'(e^{-N^{1/2}Y^-_{(a,b,I,J)}(x)}) \approx -N^{3/2} \int dx \rho(x)n_{(a,b)}Y^-_{(a,b,I,J)}(x),
$$

(A.21)

(Anti-)Fundamentals. This is again a straightforward computation using the polylog identities and imposing $f^a = \bar{f}^a$ leads to

$$
-N^{3/2} \int dx \rho(x)\pi(x) \sum_{a,\{f^a\},I,J} (n_{f^a} + \bar{n}_{f^a} - 2),
$$

(A.22)

which is what appears in the last term of (2.22).

Hessian. The log $B$ term is naïvely of $\mathcal{O}(N \log N)$ but due to the diverging nature of $\nu''(z) = -\pi \coth(\pi z)$ at $z = 0$, there arise terms of $\mathcal{O}$( inevitably $\sqrt{N}$) that contribute to $\mathcal{I}$ at the leading order. A careful splitting of divergent and non-divergent terms of log $B$ has been discussed in [24]. We will just show how the divergent term contributes to the large $N$ limit of the index. The divergence in $B$ occurs exactly when the bifundamental contribution diverges so the Hessian in large $N$ limit contributes:

$$
\delta y_{ab,IJ}(x) + \nu_{(a,b)} = 0 : N \int dx \rho(x)\log \nu''(e^{-N^{1/2}Y^+_{(a,b,I,J)}(x)}) \approx +N^{3/2} \int dx \rho(x)Y^+_{(a,b,I,J)}(x)
$$

$$
\delta y_{ab,IJ}(x) - \nu_{(b,a)} = 0 : N \int dx \rho(x)\log \nu''(e^{-N^{1/2}Y^-_{(a,b,I,J)}(x)}) \approx +N^{3/2} \int dx \rho(x)Y^-_{(a,b,I,J)}(x),
$$

where we used that $\lim_{z \to 0} \nu''(z) = -z^{-1}$. Combining above expressions with the bifundamental contributions (A.21), we get the total divergent contribution to the twisted index as:

$$
\delta y_{ab,IJ}(x) \pm \nu_{(\cdot)} = 0 : N^{3/2} \int dx \rho(x)n_{(\cdot)}Y^{\pm}_{(a,b,I,J)}(x),
$$

(A.23)

which appears in the last line of (2.22) with the Kronecker $\delta$ enforcing the condition on $\delta y(x)$’s.

---

18This terminology makes sense in the case of ABJM and other theories which have only 2 regions. As we saw in explicit examples of $A_3$ and $D_4$, there is no clear demarcation between tail regions and non-tail regions.

19Recall that $v$ depends on $v(u'_{a} - u''_{b} + \cdots)$ and $B = \det_{a_i,b_j} \frac{\partial^r v}{\partial u_{i}^r \partial n_{u}^j}$ so $B$ would depend on $v''(\cdots)$.
