ABSTRACT

A set of classical solutions of a singular type is found in a 5D SUSY bulk-boundary system. The ”parallel” configuration, where the whole components of fields or branes are parallel in the iso-space, naturally appears. It has three free parameters related to the scale freedom in the choice of the brane-matter sources and the ”free” wave property of the extra component of the bulk-vector field. The solutions describe brane, anti-brane and brane-anti-brane configurations depending on the parameter choice. Some solutions describe the localization behaviour even after the non-compact limit of the extra space. Stableness is assured. Their meaning in the brane world physics is examined.

1 Mirabelli-Peskin Model Let us consider the 5 dimensional flat space-time with the signature (-,1,1,1,1). The space of the fifth component is taken to be $S_1$, with the periodicity $2l$, and has the $Z_2$-orbifold condition ($x^5 \leftrightarrow -x^5$). We take a 5D bulk theory $\mathcal{L}_{\text{bulk}}$ which is coupled with a 4D matter theory $\mathcal{L}_{\text{bnd}}$ on a ”wall” at $x^5 = 0$ and with $\mathcal{L}_{\text{bnd}}'$ on the other ”wall” at $x^5 = l$: $S = \int_{l}^{0} dx^5 \int d^4x \{ \mathcal{L}_{\text{bnd}} + \delta(x^5) \mathcal{L}_{\text{bnd}} + \delta(x^5 - l) \mathcal{L}_{\text{bnd}}' \}$.

We take the Mirabelli-Peskin model[2] as an example. The bulk dynamics is given by the 5D super YM theory (a vector field $A^M$ ($M = 0, 1, 2, 3, 5$), a scalar field $\Phi$, a doublet of symplectic Majorana fields $\lambda^i$ ($i = 1, 2$), and a triplet of auxiliary scalar fields $X^a$ ($a = 1, 2, 3$)): $\mathcal{L}_{\text{YM}} = -\frac{1}{4} \text{tr} F_{MN}^2 - \text{tr} (\nabla^M \Phi)^2 - i \text{tr} (\lambda^a \gamma^M \nabla_M \lambda^i) + \text{tr} (X^a)^2 + g \text{tr} (\lambda^i \Phi, \lambda^j)$.

It is known that we can consistently project out $\mathcal{N} = 1$ SUSY multiplet by assigning $Z_2$-parity to all fields in accordance with the 5D SUSY. A consistent choice is given as: $P = +1$ for $A^m, \lambda_L, X^3$; $P = -1$ for $A^5, \Phi, \lambda_R, X^1, X^2$ ($m = 0, 1, 2, 3$). Then ($A^m, \lambda_L, X^3 - \nabla_5 \Phi$) constitute an $\mathcal{N} = 1$ vector multiplet. Especially $D \equiv X^3 - \nabla_5 \Phi$ plays the role of $D$-field on the wall. We introduce one 4D chiral multiplet $(\phi, \psi, F)$ on the $x^5 = 0$ wall and the other one $(\phi', \psi', F')$ on the $x^5 = l$ wall. These are the simplest matter candidates and were taken in the original paper[2]. Using the $\mathcal{N} = 1$ SUSY property of the fields ($A^m, \lambda_L, X^3 - \nabla_5 \Phi$), we can find the following bulk-boundary coupling on the $x^5 = 0$ wall.

\[
\mathcal{L}_{\text{bnd}} = - \nabla_m \phi \nabla^m \phi - \psi^i \bar{\sigma}^m \nabla_m \psi + F^i F + \sqrt{2} g (\bar{\psi} \lambda_L \phi - \phi^i \lambda_L \psi) + g \phi^i D \phi + \mathcal{L}_{\text{SupPot}},
\]

\[
\mathcal{L}_{\text{SupPot}} = \left( \frac{1}{2} m_{\alpha \beta} \Theta^\alpha_{\alpha} \Theta^\beta_{\beta} + \frac{1}{3!} \lambda_{\alpha \beta \gamma} \Theta^\alpha_{\alpha} \Theta^\beta_{\beta} \Theta^\gamma_{\gamma} \right) |g|^2 + \text{h.c.}, \quad (1)
\]

where $\nabla_m \equiv \partial_m + ig A_m$, $D = X^3 - \nabla_5 \Phi$, $\Theta = \phi + \sqrt{2} \theta \psi + \theta^2 F$. We take the fundamental representation for $\Theta = (\phi, \psi, F)$. In the same way, we introduce the coupling between the other matter fields $(\phi', \psi', F')$ on the $x^5 = l$ wall and the bulk fields: $\mathcal{L}_{\text{bnd}}' = (\phi \rightarrow \phi', \psi \rightarrow \psi', F \rightarrow F' \text{ in } \Box)$. We note the interaction between the bulk fields and the boundary ones is definitely fixed from SUSY.

aBased on the work with AKIHIRO MURAYAMA[1]
2 Vacuum Structure

Generally the vacuum is determined by the potential part of scalar fields. We first reduce the previous system to the part which involves only scalar fields or the extra component of the bulk vector.

\[
L_{\text{blk}}^{\text{red}}[\Phi, X^3, A_5] = \text{tr} \left\{ -\partial_M \Phi \partial^M \Phi + X^3 X^3 - \partial_M A_5 \partial^M A_5 + 2g(\partial_5 \Phi \times A_5)\Phi \\
- \frac{1}{c^2}(A_5 \times \Phi)(A_5 \times \Phi) - 2\partial_M A_5 \cdot \partial^M c - 2ig\partial_5 \Phi \cdot [A_5, c] \right\},
\]

where we have dropped terms of \(X^1\) and \(X^2\) because they decouple from other fields. The field \(c\) is the ghost field. While \(L_{\text{blk}}\) on the \(x^5 = 0\) wall, reduces to

\[
L_{\text{blk}}^{\text{red}}[\phi, \phi^\dagger, X^3 - \nabla_5 \Phi] = -\partial_m \phi^\dagger \partial^m \phi + g(X^3 - \nabla_5 \Phi)\phi^\dagger(T^\alpha)_{\beta\gamma} \phi_{\gamma'} + F^\dagger F + \left\{ \frac{\lambda_{\alpha'\beta'\gamma'}}{3!}(\phi_{\alpha'\beta'}F_{\gamma'} + \phi_{\alpha'\gamma'}F_{\beta'} + F_{\alpha'\beta'}\phi_{\gamma'}) + h.c. \right\}.
\]

In the same way, we obtain \(L_{\text{blk}}^{\text{red}}[\phi', \phi'^\dagger, X^3 - \nabla_5 \Phi]\) on the \(x^5 = l\) wall by replacing, in \([3]\), \(\phi\) and \(\phi^\dagger\) by \(\phi'\) and \(\phi'^\dagger\), respectively.

The vacuum is usually obtained by the constant solution of the scalar-part field equation. In higher dimensional models, however, extra-coordinate(s) can be regarded as parameter(s) which should be separately treated from the 4D space-time coordinates. In this standpoint, it is the more general treatment of the vacuum that we allow the \(x^5\)-dependence on the bulk-part of the solution. We generally call the classical solutions \((\varphi, \chi^3, a_5; \eta, \eta', f, f')\) the background fields. \(^b\) They satisfy the field equations derived from \([2]\) and \([3]\) (on-shell condition).

Assuming \(\varphi = \varphi(x^5), \chi^3 = \chi^3(x^5), a_5 = a_5(x^5), \eta = \text{const}, \eta' = \text{const}, f = \text{const}, f' = \text{const}\), the field equation of \(L_{\text{blk}}^{\text{red}}[\phi, \phi^\dagger, A_5, f, f'] = 0\) the bulk-fields variation,\(^{4}\)

\[
\delta \Phi_\alpha - \partial_5 Z_\alpha - g(Z \times a_5)_\alpha = 0, \quad \delta A_{5\alpha}; \quad \partial_5^2 a_{5\alpha} - g(\varphi \times Z)_\alpha = 0, \quad \delta X^3_\alpha; \quad \chi^3_\alpha + g(\delta(x^5)\eta^\dagger T^\alpha \eta + \delta(x^5 - l)\eta l T^\alpha \eta') = 0, \quad (4)
\]

where \(Z_\alpha \equiv -g(\delta(x^5)\eta^\dagger T^\alpha \eta + \delta(x^5 - l)\eta l T^\alpha \eta') - \partial_5 \varphi_\alpha + g f_{\alpha\beta\gamma} a_{5\beta\gamma} \varphi_\gamma\). The field equations for the boundary-fields part are given by the variations \(\delta \Phi_{\alpha'}\) \(\delta \Phi_{\alpha'}\) \(\delta F_{\alpha'}\) \(\delta F_{\alpha'}\):

\[
d_{\beta}[x^2=0 \times (T^\beta \eta)]_{\alpha'} + m_{\alpha'\beta'} f_{\beta'}^\dagger + \frac{1}{2} \lambda_{\alpha'\beta'\gamma'} \eta^\dagger_{\beta'} f_{\gamma'}^\dagger = 0, \quad (\eta \rightarrow \eta', f \rightarrow f' \text{ in the left equation}), \quad f_{\alpha'} + \frac{1}{2} \lambda_{\alpha'\beta'\gamma'} \eta^\dagger_{\beta'} \eta^\dagger_{\gamma'} = 0, \quad (\eta \rightarrow \eta', f \rightarrow f' \text{ in the left equation}),
\]

where \(d_\alpha = (\chi^3 - \partial_5 \varphi + g a_5 \times \varphi)_\alpha\) is the background D-field. From the equation \([4]\), we obtain \(\chi^3_\alpha = -g(\delta(x^5)\eta^\dagger T^\alpha \eta + \delta(x^5 - l)\eta l T^\alpha \eta')\), and we know \(Z_\alpha = d_\alpha\).

Before presenting the solution, we note a simple structure involved in them. Under the "parallel" circumstance, \(a_{5\alpha} \propto \varphi_\alpha \propto \eta^\dagger T^\alpha \eta \propto \eta^\dagger T^\alpha \eta'\), the equations for \(\delta \Phi_\alpha\) and \(\delta A_{5\alpha}\) are \(\partial_5^2 \varphi_\alpha = -g \partial_5(\delta(x^5)\eta^\dagger T^\alpha \eta + \delta(x^5 - l)\eta l T^\alpha \eta')\) and \(\partial_5^2 a_{5\alpha} = 0\). The first one is a static wave equation with "source" fields located at \(x^5 = 0\) and \(l\). It is easily integrated

\(^b\)In the background field treatment\([3]\)we expand all fields around the background fields: \(\varphi + \Phi, \chi^3 + X^3, a_5 + A_5, \eta + \phi, \eta' + \phi', f + F, f' + F'\)
The equation of $a_{5\alpha}$ is a (static) "free" wave equation (no source fields). $a_{5\alpha}$ do not receive, in the "parallel" environment, any effect from the boundary sources $\eta, \eta'$. This characteristically shows the difference between the bulk scalar $\Phi_\alpha$ and the extra component of the bulk vector $A_{5\alpha}$ in the vacuum configuration.

We first solve (4) with respect to $a_{5\alpha}$ and $\varphi_\alpha$. They also give the solutions for $\chi_\alpha^3$ and $d_\alpha = Z_\alpha$. Using these results we solve (5) with respect to $\eta, \eta', f$ and $f'$ for given values of $m_{\alpha'\beta'}$ and $\lambda_{\alpha'\beta'\gamma'}$. Here we seek a natural solution by requiring that $d_\alpha (= Z_\alpha)$ is independent of $x^5$. Then, from the equation of (4), we have $Z \times a_5 = 0$. It says that we may consider the three cases: 1) $a_{5\alpha} = 0$, 2) $Z_\alpha = 0$, 3) $a_{5\alpha} \propto Z_\alpha (\neq 0)$.

The case 3) solution is given by

$$\varphi_\alpha = \bar{\varphi}_\alpha \{c_1 x^5_p + [x^5 - l]_p\}, \quad a_{5\alpha} = \bar{a}_\alpha \{c_2 x^5_p + [x^5 - l]_p\}, \quad \eta = \text{const}, \quad \eta' = \text{const}, \quad \bar{a}_\alpha = c_3 \bar{\varphi}_\alpha, \quad \bar{\varphi}_\alpha = \frac{g}{2l} \eta^T \alpha \eta = \frac{1}{c_1} \frac{g}{2l} \eta^T \alpha \eta', \quad \chi_\alpha^3 = -g \{\delta(x^5) + c_1 \delta(x^5 - l)\} \eta^T \alpha \eta, \quad Z_\alpha = d_\alpha = \frac{-g}{2l} (1 + c_1) \eta^T \alpha \eta, \quad \partial_5 (\delta A_{5\alpha}) |_{x^5 = 0} = 0, \quad (6)$$

where $c_1, c_2$ and $c_3$ are three free parameters. The meaning of $c_1$ is the scale freedom in the "parallel" condition of brane sources $\eta^T \alpha \eta' \propto \eta^T \alpha \eta$, and that of $c_2$ and $c_3$ is the "free" wave property of $a_{5\alpha}$. The bulk scalar configuration influences the boundary source fields through the parameter $c_1$, whereas the bulk vector (5th component) does not have such effect. Instead the latter one satisfies the field equation only within the restricted configuration (Neumann boundary condition). This solution includes the case 1) as $c_3 = 0$ and case 2) as $c_1 = -1$. Another special cases are given by fixing two parameters, $c_1$ and $c_2$ (keeping the $c_3$-freedom), as shown in Table 1.

We have solved only (4). When $m_{\alpha'\beta'}$ and $\lambda_{\alpha'\beta'\gamma'}$ are given, the equations (5) should be furthermore solved for $\eta, \eta', f$ and $f'$ using the obtained result. The solutions in the second row ($c_1 = -1$) of Table 1 correspond to the SUSY invariant vacuum, irrespective of whether the vacuum expectation values of the brane-matter fields ($\eta$ and $\eta'$) vanish or not. For other solutions, however, $d_\alpha$ depends on $\eta$ or $\eta'$, hence the SUSY symmetry of the vacuum is determined by the brane-matter fields. The eqs. (5) have a 'trivial' solution $\eta = 0, f = 0$ (or $\eta' = 0, f' = 0$) when $d_\alpha = -\frac{g}{2l} \eta^T \alpha \eta$ (or $d_\alpha = -\frac{g}{2l} \eta'^T \alpha \eta'$). It corresponds to the SUSY invariant vacuum. If the equations have a solution $\eta \neq 0$ (or $\eta' \neq 0$), it corresponds to a SUSY-breaking vacuum.

We see the bulk scalar $\Phi$ is localized on the wall(s) where the source(s) exists, whereas the extra component of the bulk vector $A_5$ on the wall(s) where the Neumann boundary condition is imposed. The two cases, ($c_1 = -1, c_2 = -1$) and ($c_1 = 1/0, c_2 = 1/0$), are treated in [4].

3 Stability In the present approach, ($\mathcal{N} = 1$)SUSY is basically respected. If SUSY is preserved, the solutions obtained previously are expected to be stable, because the force between branes (Casimir force) vanish from the symmetry. In some cases, we can more strongly confirm the stableness from the topology (or index) as follows. We can regard the extra-space size ($S^1$ radius) $l$ as an infrared regularization parameter for the non-compact extra-space $\mathbb{R} (-\infty < y < \infty)$. An interesting case is the $l \to \infty$ limit of
\( c_1 = -1, c_2 = -1 \) in Table 1: \( \varphi_\alpha = -\bar{\varphi}_\alpha \epsilon(x^5) \rightarrow -\frac{a}{2} \eta^\alpha \bar{\eta} \epsilon(x^5), \ a_{5\alpha} = -\bar{a}_\alpha \epsilon(x^5) \rightarrow -c_1 \frac{a}{2} \eta^\alpha \bar{\eta} \epsilon(x^5), \ x_\alpha^3 = -\delta(x^5) \eta^\alpha \bar{\eta}, \ Z_\alpha = d_\alpha = 0, \ \partial_5 (\delta A_{5\alpha})|_{x^5 = 0} = 0. \) The above limit is a solution of \( S = \int d^4 x \int_{-\infty}^\infty dx^5 \{ \mathcal{L}_{blk} + \tilde{\delta}(x^5) \mathcal{L}_{bnd} \}, \ -\infty < x^5 < \infty, \) where \( \mathcal{L}_{blk} \) and \( \mathcal{L}_{bnd} \) are the same as before except that fields are no more periodic. The stableness is clear from the same situation as the kink solution. On the other hand, in the \( l \rightarrow \infty \) limit of \( (c_1 = 1/0, c_2 = 1/0) \) there remains no localization configuration.

4 Conclusion In the brane system appearing in string/D-brane theory, the stableness is the most important requirement. We find some stable brane configurations in the SUSY bulk-boundary theory. We systematically solve the singular field equation using a general mathematical result about the free-wave solution in \( S_1/Z_2 \)-space[1]. The two scalars, the extra-component of the bulk-vector \((A_5)\) and the bulk-scalar \((\Phi)\), constitute the solutions. Their different roles are clarified. The importance of the ”parallel” configuration is disclosed. The boundary condition (of \( A_5 \)) and the boundary matter fields are two important elements for making the localized configuration. Among all solutions, the solution \( (c_1 = -1, c_2 = -1) \) is expected to be the thin-wall limit of a kink solution.

In ref.[4,3], the 1-loop effective potential is obtained for the backgrounds \( (c_1 = -1, c_2 = -1) \). In ref.[6], a bulk effect in the 1-loop effective potential is analyzed in relation to the SUSY breaking. We hope the family of present solutions will be used for further understanding of the bulk-boundary system.
