Abstract

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia, and it increases in prevalence with advancing age to about 5% in people older than 65 years (Table 1). The chance of developing atrial fibrillation at age 40 years or older is about 25% in men and women. This arrhythmia accounts for about one-third of all strokes, and 30% of all patients with atrial fibrillation have a family history of the disease [1].

When the atria are in fibrillation, contraction occurs at rates of 350–900 per minute. The AV node may conduct these impulses to the ventricles at 90–170 beats per minute, and often higher. There are several complementary and competing theories regarding the pathophysiology of AF initiation and propagation. The occasional impulses conducted by the atrio-ventricular node results in a totally irregular ventricular rhythm which is a characteristic of the condition which can be either continuous (acute or chronic) or paroxysmal [2].

Achalasia is primarily associated with a degeneration of ganglion cells of Auerbach's plexus resulting in an absence of oesophageal peristalsis and failure of lower oesophageal sphincter relaxation. This results in oesophageal dilatation or mega-oesophagus [3].

We present a rare case of a patient with achalasia in which accumulation of undigested food lead to mega-oesophagus and atrial fibrillation.

Case presentation

An 84-year-old Caucasian women referred by her General Practitioner complaining of dysphagia and dyspnoea...
exacerbated by swallowing. She reported a 3 week history of progressive dysphagia, initially for solids and subsequently for fluids leading to total dysphagia. Other reported symptoms included regurgitation, cough and hoarseness of voice. There was no significant medical, family or social history.

Clinical examination revealed a rapid, irregularly irregular pulse; no other cardiovascular-respiratory abnormalities were identified. Abdominal examination also revealed no abnormality; indirect laryngoscopy which was carried out by the same examining clinician showed pooling of saliva in the hypopharynx.

Lateral soft tissue radiograph (Figure 1) revealed widening of the upper mediastinum and subsequent barium swallow (Figure 2) showed achalasia with food debris filling the cervical oesophagus. An electrocardiogram (ECG) showed evidence of ischaemia and atrial fibrillation with a ventricular response rate of 120–150 (Figure 3). Haematological and biochemical laboratory investigations were within the normal limits.

The patient was initially resuscitated with intravenous fluids, followed by naso-oesophageal leverage and removal of 300 ml of retained food debris from the cervical oesophagus. An ECG performed 8 hours afterwards revealed reversion back to sinus rhythm (Figure 4). Eventually the patient underwent fibre optic balloon dilatation of the distal oesophageal stricture with multiple biopsies which revealed no malignancy. Following the procedure the patient remained asymptomatic.

**Table 1: Causes of Atrial Fibrillation**

| Atrial Fibrillation |
|---------------------|
| **Common causes**   |
| Heart failure       |
| Hypertension        |
| Cardiac ischemia    |
| Myocardial infarction |
| Mitral valve disease |
| Pneumonia           |
| Hyperthyroidism     |
| Alcohol             |
| Postoperative AF    |
| **Rare causes**     |
| Cardiomyopathy      |
| Constrictive pericarditis |
| Sick sinus syndrome |
| Bronchial carcinoma |
| Atrial myxoma       |
| Endocarditis        |
| Haemochromatosis    |
| Sarcoidosis         |

Figure 1
Lateral soft tissues X-ray revealing undigested material in the cervical oesophagus.

**Conclusion**

There is a correlation between achalasia and cardiac arrhythmia [4]. Many patients with achalasia are known to perform a temporary valsalva manoeuvre to aid the transit of food over the functionally stenotic segment of their oesophagus. The anatomical proximity of the oesophagus with the left atria is further evidenced by the rare but severe complication of left atrial radiofrequency ablation of oesophageal perforation and mediastinitis [5].

Using 3 non-invasive tests, abnormalities of cardiovascular reflex function were found in 7 of 15 patients with achalasia. Abnormalities of heart rate responses to the valsalva manoeuvre, deep breathing, and standing were noted in patients with autonomic neuropathy defect. The findings are consistent with the hypothesis that an abnormality of vagal function may contribute to the pathogenesis of achalasia [6].

Achalasia itself may be a result of an abnormality of vagal function due to an autonomic neuropathic defect and therefore abnormalities of cardiovascular response are not uncommon [7].
In this patient, the removal of the food debris from the cervical oesophagus caused reversion of this arrhythmia back into sinus rhythm. This can be justified as either due to vagal repression or the relief of the pressure effect of the volume of the food debris transmitted directly to the atria. The evacuation may have resulted in either a sinus massage or a forced valsalva leading to reversion of the rhythm.

There are several confounding factors as to the exact cause of the transient atrial arrhythmia in this patient. Previous electrocardiograms exhibit a degree of ischaemia which may predispose to transient arrhythmias in situations of vagal repression especially in the circumstances of extra-cardiac intra-thoracic pathology as in this case.
