Abstract

In this paper, a linear univariate representation for the roots of a zero-dimensional polynomial equation system is presented, where the roots of the equation system are represented as linear combinations of roots of several univariate polynomial equations. The main advantage of this representation is that the precision of the roots can be easily controlled. In fact, based on the linear univariate representation, we can give the exact precisions needed for isolating the roots of the univariate equations in order to obtain the roots of the equation system to a given precision. As a consequence, a root isolation algorithm for a zero-dimensional polynomial equation system can be easily derived from its linear univariate representation.

Key words: Zero-dimensional polynomial system, linear univariate representation, local generic position, root isolation

1. Introduction

Solving polynomial equation systems is a basic problem in the field of computational science and has important engineering applications. In most cases, we consider zero-dimensional polynomial systems. We will discuss how to solve this kind of systems in this paper. In particular, we will consider how to isolate the complex roots for such a system.

One of the basic methods to solve polynomial equation systems is based on the concept of separating elements, which can be traced back to Kronecker [14] and has been studied extensively in the past twenty years [2; 4; 8; 9; 10; 11; 12; 13; 19; 20; 24]. The idea of the method is to introduce a new variable \( t = \sum c_i x_i \) which is a linear combination of the variables to be solved such that \( t = \sum c_i x_i \) takes different values when evaluated at different roots of the polynomial equation system \( P = 0 \). In such a case, we say that \( t \) is a separating element for \( P = 0 \). If \( t = \sum c_i x_i \) is a separating element for \( P = 0 \), the roots of \( P = 0 \) have the following rational univariate representation (RUR):

\[
f(t) = 0, x_i = R_i(t), i = 1, \ldots, n,
\]

\(^1\) Partially supported by a National Key Basic Research Project of China and by a grant from NSFC.
where $f \in \mathbb{Q}[t]$ and $R_i(t)$ are rational functions in $t$. As a consequence, solving multi-variate equation systems is reduced to solving a univariate equation $f(t) = 0$ and to substituting the roots of $f(t) = 0$ into rational functions $R_i(t)$. Along this line, better complexity bounds and effective software packages for solving polynomial equations such as the Maple package RootFinding by Rouillier (20) and the Magma package Kronecker by Giusti, Lecerf, and Salvy (11) are given.

The above approaches still have the following problem: for an isolation interval $[a, b]$ of a real root $\alpha$ of $f(u) = 0$, to determine the isolation interval of $x_i = R_i(\alpha)$ under a given precision is not a trivial task. In this paper, we propose a new representation for the roots of a polynomial system which will remedy this drawback.

In the ISSAC paper (3), based on ideas similar to separating elements, a local generic position method is introduced to solve bivariate polynomial systems and experimental results show that the method is quite efficient for solving equation systems with multiple roots. In this paper, we extend the method to solve general zero-dimensional polynomial systems. A local generic position for a polynomial equation system $P = 0$ is also a linear combination of the variables to be solved: $t = \sum c_i x_i$ which satisfies two conditions. First, $t_k = \sum_{i=1}^{k} c_i x_i$ is a separating element of $P_k = (P) \cap \mathbb{Q}[x_1, \ldots, x_k]$ for $k = 2, \ldots, n$, and the roots of $P_k = 0$ have a one-to-one correspondence with the roots of a univariate equation $T_k(t_k) = 0$. Second, for a root $\xi = (\xi_1, \ldots, \xi_k)$ of $P_k = 0$ represented by a root $\eta$ of $T_k(t_k) = 0$, all the roots $\eta_j$ of $T_{k+1}(t_{k+1}) = 0$ corresponding to the roots of $P_{k+1} = 0$, say $\xi_j = (\xi, \xi_{k+1,j})$, “lifted” from $\xi$ are projected into a fixed square neighborhood of $\eta$. This “local” property is illustrated in Figure 1. We prove that if $t_n = \sum_{i=1}^{n} c_i x_i$ is a local generic position for $P$, then the roots of $P = 0$ can be be represented as special linear combinations of the roots of univariate equations $T_k(t_k) = 0, k = 1, \ldots, n$:

$$\left\{\left(\frac{\alpha_2 - \alpha_1}{s_1}, \ldots, \frac{\alpha_n - \alpha_{n-1}}{s_1 \cdots s_{n-1}}\right) \mid T_k(\alpha_k) = 0\right\},$$

Fig. 1. The distribution of the roots of $T_i(x) = 0 (i = 1, 2, 3)$. The red diamonds (blue crosses, black circles) are roots of $T_1(x) = 0, T_2(x) = 0, T_3(x) = 0$ and red (blue) boxes are neighborhoods for the red diamonds (blue crosses).
where \( s_j \) are certain positive rational numbers and the \( \alpha_j+1 \) matching \( \alpha_j \) are in certain square neighborhood of \( \alpha_j \) to be defined in Section 2. Such a representation is called a linear univariate representation (LUR for short) of the polynomial system.

The main advantage of the LUR representation is that the precision of the roots can be easily controlled. For RUR, computing solutions with a given precision is not a trivial task as we mentioned before. It is not easy to know with which precision to isolate the roots of \( f(t) = 0 \) is enough in order for the roots of the system \( x_i = R_i(t) \) to satisfy a given precision. For LUR, precision control becomes very easy. We can give an explicit formula for the precision of the roots of \( T_i(x) = 0 \) in order to obtain the roots of the system with a given precision. So we can obtain the solutions of the system by refining the roots of \( T_i(x) = 0 \) at most once. Another advantage of LUR is that when we isolate the roots of \( T_{i+1}(x) = 0 \), we need only to consider a fixed neighborhood of each root of \( T_i(x) = 0 \).

We propose an algorithm to compute an LUR for a zero-dimensional polynomial system. The key ingredients of the algorithm are to estimate the root bounds of \( \mathcal{P} = 0 \) and to estimate the separating bounds for the roots of \( \mathcal{P}_{k+1} = 0 \) lifted from a root of \( \mathcal{P}_k = 0 \). We adopt a computational approach to estimate such bounds in order to obtain tight bound values. For the root bounds of \( \mathcal{P} = 0 \), we use Gröbner basis computation to obtain the generating polynomial of the principal ideal \( (\mathcal{P}) \cap \mathbb{Q}[x_i] \) and use this polynomial to estimate the root bound for the \( x_i \) coordinates of the roots of \( \mathcal{P} = 0 \). The separating bounds for \( \mathcal{P}_k = 0 \) are obtained from the isolating boxes for the roots of the \( T_k(x) = 0 \). These bounds in turn will be used to compute the isolating boxes for the roots of \( \mathcal{P}_{k+1} = 0 \). Hence, the algorithm to compute an LUR also gives a set of isolating boxes for the roots of \( \mathcal{P} = 0 \).

In Section 2, we give the definition of LUR and the main result of the paper. In Section 3, we present an algorithm to compute an LUR of a zero-dimensional polynomial system as well as a set of isolation boxes of the roots of the equation system. In Section 4, we provide some illustrative examples. We conclude the paper in Section 5.

2. Linear univariate representation

In this section, we will define LUR and prove its main properties. Let

\[
\mathcal{P} = \{ f_1(x_1, \ldots, x_n), \ldots, f_s(x_1, \ldots, x_n) \}
\]

be a zero-dimensional polynomial system in \( \mathbb{Q}[x_1, \ldots, x_n] \), where \( \mathbb{Q} \) is the field of rational numbers. Let

\[
\mathcal{I}_i = (\mathcal{P}) \cap \mathbb{Q}[x_1, \ldots, x_i], \quad i = 1, \ldots, n,
\]

where \( (\mathcal{P}) \) is the ideal generated by \( \mathcal{P} \). We use \( V_C(\mathcal{P}) \) to denote its complex roots in \( \mathbb{C}^n \).

Since we will use rectangles to isolate complex numbers, we adopt the following norm for a complex number \( c = x + yi \):

\[
|c| = \max\{|x|, |y|\}.
\]  

(1)

The “distance” between two complex numbers \( c_1 \) and \( c_2 \) is defined to be \(|c_1 - c_2|\). It is easy to check that this is indeed a distance satisfying the inequality \(|c_1 - c_2| \leq |c_1 - c_3| + |c_3 - c_2|\) for any complex number \( c_3 \). Let \( c_0 \) be a complex number and \( r \) a positive rational number.

* The results in this section are also valid if we use the usual distance for complex numbers.
Then the set of points having distance less than \( r \) with \( c_0 \), that is \( \{ c_1 \in \mathbb{C} \mid |c_1 - c_0| < r \} \), is an open square with \( c_0 \) as the center.

By an LUR, we mean a set like

\[
\{ T_1(x), \ldots, T_n(x), s_i, d_i, i = 1, \ldots, n - 1 \},
\]

where \( T_i(x) \in \mathbb{Q}[x] \) are univariate polynomials, \( s_i \) and \( d_i \) are positive rational numbers. The roots of (2) are defined to be

\[
\begin{align*}
\{ (\alpha_1, \frac{\alpha_2 - \alpha_1}{s_1}, \ldots, \frac{\alpha_n - \alpha_{n-1}}{s_1 \cdots s_{n-1}}) \mid & T_i(\alpha_i) = 0, i = 1, \ldots, n \quad \text{and} \\
|\alpha_{i+1} - \alpha_i| < s_1 \cdots s_{i-1} d_i, i = 1, \ldots, n - 1 \}
\end{align*}
\]

(3)

where \( s_0 = 1 \). Geometrically, we match a root \( \alpha_i \) of \( T_i(x) = 0 \) with those roots of \( T_{i+1}(x) = 0 \) inside a squared neighborhood centered at \( \alpha_i \). See Figure 1 for an illustration. An LUR for \( \mathcal{P} \) is a set of form (2) whose roots are exactly the roots of \( \mathcal{P} = 0 \).

It is clear that an LUR represents the roots of \( \mathcal{P} \) as linear combinations of the roots of some univariate polynomial equations. The LUR representation has the following advantage: we can easily derive the precision of the roots of \( \mathcal{P} = 0 \) from that of the univariate equations as shown by the following lemma.

**Lemma 1.** Let (2) be an LUR for a polynomial system \( \mathcal{P} = 0 \). If \( \alpha_i \) is a root of \( T_i(x) = 0(1 \leq i \leq n) \) and \( \overline{\alpha}_i \) is an approximation of \( \alpha_i \) with precision \( \epsilon_i \), then the approximate root \( (\overline{\alpha}_1, \frac{\overline{\alpha}_2 - \overline{\alpha}_1}{s_1}, \ldots, \frac{\overline{\alpha}_n - \overline{\alpha}_{n-1}}{s_1 \cdots s_{n-1}}) \) of \( \mathcal{P} = 0 \) has precision \( \max\{\epsilon_1, \frac{\epsilon_1 + \epsilon_i}{s_1}, \ldots, \frac{\epsilon_n + \epsilon_{n-1}}{s_1 \cdots s_{n-1}}\} \).

**Proof.** Since \( x_i = \frac{\alpha_i - \alpha_{i-1}}{s_i} \) and the approximate root \( \overline{\alpha}_i \) of \( \alpha_i \) has precision \( \epsilon_i \), the approximate root \( \overline{x}_i = \frac{\overline{\alpha}_i - \overline{\alpha}_{i-1}}{s_i} \) has precision no larger than \( \frac{\epsilon_i + \epsilon_{i-1}}{s_i \cdots s_{i-1}} \).

For a zero-dimensional polynomial system \( \mathcal{P} \), let \( d_i, r_i \ (i = 1, \ldots, n) \), and \( s_i \ (i = 1, \ldots, n - 1) \) be positive rational numbers satisfying

\[
\begin{align*}
D_i &= \min \left\{ \frac{1}{2}|\alpha - \beta|, \forall \eta \in V_C(\mathcal{I}_{i-1}), (\eta, \alpha), (\eta, \beta) \in V_C(\mathcal{I}_i), \alpha \neq \beta \right\}, \quad (4) \\
d_i &< \min \left\{ D_i, \frac{d_{i-1}}{2s_{i-1}} \right\}, \quad (5) \\
r_i &> 2\max\{|\alpha_i|, \forall (\alpha_1, \ldots, \alpha_i) \in V_C(\mathcal{I}_i)\}, \quad (6) \\
s_i &< \frac{d_i}{r_i + 1} \quad (7)
\end{align*}
\]

where \( s_0 = 1, d_0 = +\infty \). Geometrically, \( D_i \) is half of the root separation bound for roots of \( \mathcal{I}_i \) considered as points on a “fiber” over each root of \( \mathcal{I}_{i-1} \), \( r_i \) is twice the root bound for the \( i \)-th coordinates of the roots of \( \mathcal{I}_i \), and \( s_i \), the inverse of the slope of certain line, is a key parameter to be used in our method. If \( \forall \eta \in V_C(\mathcal{I}_{i-1}), \#\{\alpha| (\eta, \alpha) \in V_C(\mathcal{I}_i)\} = 1 \), we can choose any positive number as \( d_i \).
For $s_i$ satisfying (7), consider the ideal
\[ \mathcal{I}_i = (\mathcal{I}_i \cup \{ x - x_1 - s_1 x_2 - \cdots - s_1 \cdots s_{i-1} x_i \} ), \]
where $x$ is a new variable. It is clear that $\mathcal{I}_i$ is a zero-dimensional ideal in $\mathbb{Q}[x_1, \ldots, x_i, x]$. And the elimination ideal $(\mathcal{I}_i) \cap \mathbb{Q}[x]$ is principal. Let $T_i(x)$ be the generator of this ideal:
\[ (\mathcal{I}_i) \cap \mathbb{Q}[x] = (T_i(x)) . \] (9)

The following is the main result of this paper.

**Theorem 2.** If $d_i, s_i$ satisfy conditions (5), (7) and $T_i$ is defined in (9), then the corresponding set (2) is an LUR for $\mathcal{P}$.

We will prove two lemmas which will lead to a proof for the theorem. For a root $\eta_i$ of $T_i(x) = 0$, let
\[ S_{\eta_i} = \{ \eta \in \mathbb{C} | |\eta - \eta_i| < \rho_i \}, i = 1, \ldots, n \] (10)
where $\rho_i = s_1 \cdots s_{i-1} d_i (s_0 = 1)$. Note that $S_{\eta_i}$ is an open square whose center is $\eta_i$ and whose edge has length $2\rho_i$. With this notation, the roots of (2) can be written as
\[ \{ (\alpha_1, \cdots, \alpha_n) | T_i(\alpha_i) = 0, i = 1, \ldots, n \} \]
(11)
\[ \alpha_{i+1} \in S_{\alpha_i}, i = 1, \ldots, n-1 \}

In Figure 1, $S_{\eta_i}$ are interior parts of the squares. We have

**Lemma 3.** Under assumptions of Theorem 2, we have $S_{\eta_{i+1}} \subset S_{\eta_i}, i=1, \ldots, n-1$, where $(\xi_1, \ldots, \xi_{i+1}) \in V_{\mathbb{C}}(\mathcal{I}_{i+1})$ and
\[ \eta_i = \xi_1 + s_1 \xi_2 + \cdots + s_{i-1} \xi_i, \]
(12)
\[ \eta_{i+1} = \xi_1 + s_1 \xi_2 + \cdots + s_i \xi_i + s_1 \cdots s_{i-1} \xi_{i+1} = \xi_1 + s_1 \cdots s_i \xi_{i+1}. \]
(13)

**Proof.** From the definition of $\mathcal{I}_i$ in (8), $\eta_i$ is a root of $T_i(x) = 0$, $\eta_{i+1}$ is a root of $T_{i+1}(x) = 0$, and each root of $T_{i+1}(x) = 0$ has the form (13).

We first prove that $\eta_{i+1} \in S_{\eta_i}$. Using (6) and (7), we have
\[ |\eta_{i+1} - \eta_i| = s_1 \cdots s_{i|\xi_{i+1}|} \leq \frac{1}{2} s_1 \cdots s_{i-1} \leq \frac{1}{2} s_1 \cdots s_{i-1} d_i = \frac{1}{2} \rho_i. \]
(14)
As a consequence, $\eta_{i+1}$ is in $S_{\eta_i}$.

We now prove that $S_{\eta_{i+1}} \subset S_{\eta_i}$. By (5), we have $\rho_{i+1} = s_1 \cdots s_s d_{i+1} < \frac{1}{2} s_1 \cdots s_{i-1} d_i = \frac{1}{2} \rho_i$. Therefore, for any $\eta \in S_{\eta_{i+1}}$, by (14), we have $|\eta - \eta_i| \leq |\eta - \eta_{i+1}| + |\eta_{i+1} - \eta_i| < \rho_{i+1} + \frac{1}{2} \rho_i < \rho_i$. Hence $\eta \in S_{\eta_i}$ and the lemma is proved.  

For rational numbers $a_j$, we call $f_i = \sum_{j=1}^{i} a_j x_j$ a **separating element** of $\mathcal{I}_i$, if $\forall \alpha, \beta \in V_{\mathbb{C}}(\mathcal{I}_i)$, $\alpha \neq \beta$ implies $f_i(\alpha) \neq f_i(\beta)$ (see paper [21]).

Theorem 2 follows from (d) of the following lemma.
Lemma 4. Under assumptions of Theorem 2, for \( i = 1, \ldots, n \), we have

(a) \( x = x_1 + s_1 x_2 + \cdots + s_1 \cdots s_{i-1} x_1 \) is a separating element of \( \mathcal{I}_i \).

(b) Each root \( \eta_i \) of \( T_i(x) = 0 \) is in an \( S_{\eta_i} \), for a root \( \eta_{i-1} \) of \( T_{i-1}(x) = 0 \). Furthermore, if \( \eta_{i-1} = \xi_1 + s_1 \xi_2 + \cdots + s_1 \cdots s_{i-2} \xi_{i-1} \), then all roots of \( T_i(x) = 0 \) in \( S_{\eta_{i-1}} \) are of the form

\[
\eta_i = \eta_{i-1} + s_1 \cdots s_{i-1} \xi_i
\]

(15)

where \( (\xi_1, \ldots, \xi_{i-1}, \xi_i) \in V_C(\mathcal{I}_i) \).

(c) \( S_{\eta_i} \) are disjoint for all roots \( \eta_i \) of \( T_i(x) = 0 \).

(d) \( (T_1(x), \ldots, T_i(x), s_j, d_j, j = 1, \ldots, i-1) \) is an LUR for \( \mathcal{I}_i \).

Proof. We will prove the lemma by induction on \( k = i \). For \( k = 1 \), since \( (\mathcal{I}_1) = (T_1(x)) \), statements (a) and (d) are obviously true. We do not need prove (b). From (5), we have \( \varepsilon \), \( \varepsilon \) proves equation (15) and hence statement (b).

We now prove statement (c). Use notations in (12) and (13). By Lemma 3, \( \eta_{i+1} = \eta_i + s_1 \cdots s_i \xi_{i+1} \) is different from \( \theta_{i+1} = \theta_i + s_1 \cdots s_i \beta_{i+1} \). Then, \( \eta_{i+1} = s_1 \cdots s_i \beta_{i+1} \) is disjoint. Statement (c) is proved.

Suppose that the result is correct for \( k = 1, \ldots, i \). We will prove the result for \( k = i+1 \).

We first prove statement (a). Let \( \xi = (\xi_1, \ldots, \xi_{i+1}) \) and \( \beta = (\beta_1, \ldots, \beta_{i+1}) \) be two distinct elements in \( V_C(\mathcal{I}_{i+1}) \). We consider two cases. If \( (\xi_1, \ldots, \xi_i) \) is different from \( (\beta_1, \ldots, \beta_i) \), then by the induction hypothesis \( \eta_i = \xi_1 + s_1 \xi_2 + \cdots + s_1 \cdots s_{i-1} \xi_i \) is also different from \( \theta_i = \beta_1 + s_1 \beta_2 + \cdots + s_1 \cdots s_{i-1} \beta_i \). By (c) of the induction hypothesis, \( S_{\eta_i} \) and \( S_{\theta_i} \) are disjoint. By Lemma 3, \( \eta_{i+1} = \eta_i + s_1 \cdots s_i \xi_{i+1} \in S_{\eta_i} \) and \( \theta_{i+1} = \theta_i + s_1 \cdots s_i \beta_{i+1} \in S_{\theta_i} \). Then, in this case we have \( \eta_{i+1} \neq \theta_{i+1} \). In the second case, we have \( (\xi_1, \ldots, \xi_i) = (\beta_1, \ldots, \beta_i) \). Then, \( \eta_i = \theta_i \) and \( \xi_{i+1} \neq \beta_{i+1} \). It is clear that \( \eta_{i+1} = \eta_i + s_1 \cdots s_i \xi_{i+1} \) is different from \( \theta_{i+1} = \theta_i + s_1 \cdots s_i \beta_{i+1} \). Thus, (a) is proved.

We now prove statement (b). Use notations in (12) and (13). By Lemma 3, we have \( \eta_{i+1} \in S_{\eta_i} \). Then, each root of \( T_{i+1}(x) = 0 \) is in an \( S_{\eta_i} \) for a root \( \eta_i \) of \( T_i(x) = 0 \). Let \( (\beta_1, \ldots, \beta_{i+1}) \in V_C(\mathcal{I}_{i+1}) \) such that \( \theta_{i+1} = \beta_1 + s_1 \beta_2 + \cdots + s_1 \cdots s_{i+1} \beta_{i+1} \) is an other element in \( S_{\eta_i} \). We claim that \( (\beta_1, \ldots, \beta_{i+1}) \) must be the same as \( (\xi_1, \ldots, \xi_{i+1}) \). Otherwise, by the induction hypothesis (a), \( \theta_i = \beta_1 + s_1 \beta_2 + \cdots + s_1 \cdots s_{i-1} \beta_i \) is different from \( \eta_i \). By the induction hypothesis (c), \( S_{\eta_i} \) and \( S_{\theta_i} \) are disjoint which is impossible since by Lemma 3, \( \theta_{i+1} \in S_{\eta_i} \) and \( \theta_{i+1} \in S_{\theta_i} \). Thus, \( (\beta_1, \ldots, \beta_i) = (\xi_1, \ldots, \xi_i) \) and hence \( \theta_{i+1} = \eta_i + s_1 \cdots s_i \beta_{i+1} \). This proves equation (15) and hence statement (c).

Finally, we prove statement (d). Let \( \xi = (\xi_1, \ldots, \xi_{i+1}) \in V_C(\mathcal{I}_{i+1}) \) and \( \eta_j = \xi_1 + s_1 \xi_2 + \cdots + s_1 \cdots s_{j-1} \xi_{j+1} \) for \( j = 1, \ldots, i+1 \). By the induction hypothesis, we have \( \xi_j = \xi_j \in S_{\eta_j} \). Note that the inequality is equivalent to that \( \eta_{j+1} \in S_{\eta_j} \). By (15), we can recover the \( \xi_{i+1} \) with the following equation

\[
\xi_{i+1} = \frac{\eta_{i+1} - \eta_i}{s_1 \cdots s_i}
\]
From Lemma 3, we have \( \eta_{i+1} \in S_n \) or equivalently \( |\eta_{i+1} - \eta_i| < s_1 \cdots s_{i-1}d_i \). Then the root \((\xi_1, \ldots, \xi_{i+1}) = \left(\eta_1, \frac{n+\eta_2}{s_1}, \ldots, \frac{n+i+\eta_i}{s_{i-1}}\right)\) is a root of the LUR \((T_1(x), \ldots, T_{i+1}(x), s_j, d_j, j = 1, \ldots, i)\). We thus proved that the roots of \( \mathcal{I}_{i+1} \) are the same as the roots of the LUR and hence statement (d).

We have the following corollaries.

**Corollary 5.** If (2) is an LUR for a polynomial system \( \mathcal{P} \), then the roots of \( \mathcal{I}_i = 0 \) are in a one to one correspondence with the roots of \( T_i(x) = 0 \) for \( i = 1, \ldots, n \).

**Proof.** Let \( \xi = (\xi_1, \ldots, \xi_i) \in V(\mathcal{I}_i) \). Then \( \eta_i = \xi_1 + s_1 \xi_2 + \cdots + s_i \cdots s_{i-1} \xi_i \) is a root of \( T_i(x) = 0 \). By (a) of Lemma 4, this mapping is injective. This mapping is clearly surjective.

**Corollary 6.** The real roots of \( \mathcal{P} = 0 \) are in a one to one correspondence with the real roots of \( T_n(x) = 0 \). More precisely, if \( \alpha_n \) is a real root of \( T_n(x) = 0 \), then in the corresponding root \((\alpha_1, \frac{\alpha_2-\alpha_1}{s_1}, \ldots, \frac{\alpha_n-\alpha_{n-1}}{s_{n-1}})\) of \( \mathcal{P} = 0 \), \( \alpha_i \) is a real root of \( T_i(x) = 0 \), \( i = 1, \ldots, n-1 \).

**Proof.** For each root \( \eta \) of \( T_{i-1}(x) = 0 \), let \( S_\eta \) be the open square neighborhood of \( \eta \) defined in (10). We claim that a real root of \( T_i(x) = 0 \) cannot be in \( S_\eta \) for a complex root \( \eta \) of \( T_{i-1}(x) = 0 \). Since \( T_{i-1}(x) \) has rational numbers as coefficients, the complex roots of \( T_{i-1}(x) = 0 \) appear as pairs which are symmetric with the real axis and the open square neighborhoods for a pair of complex roots are disjoint. Then the open square neighborhood of any complex root has no intersection with the real axis. This proves the claim. As a consequence, if \( \alpha_n \) is a real root of \( T_n(x) = 0 \), then \( \alpha_i \) is in the open square neighborhood of a real root \( \alpha_{n-1} \) of \( T_{n-1}(x) = 0 \). Repeating the process, we obtain a real root \((\alpha_1, \frac{\alpha_2-\alpha_1}{s_1}, \ldots, \frac{\alpha_n-\alpha_{n-1}}{s_{n-1}})\) for \( \mathcal{P} = 0 \) where all \( \alpha_i \) are real numbers. The other side is obvious; a real root of \( \mathcal{P} = 0 \) will correspond to a real root of \( T_n(x) = 0 \).

From the lemma, we can consider the real roots of an LUR if we only interest in the real roots of \( \mathcal{P} = 0 \).

3. **Algorithm for computing an LUR and roots isolation**

In this section, we will present an algorithm to compute an LUR for a zero-dimensional polynomial system. The algorithm will isolate the roots of the system in \( \mathbb{C}^n \) at the same time.

3.1. **Complex isolation intervals and isolation boxes**

We introduce some basic concepts of interval computation. For more details, we refer to [17].

Let \( \mathbb{I} \mathbb{Q} \) denote the set of intervals of the form \([a, b] \), where \( a \leq b \in \mathbb{Q} \). The **length** of an interval \( I = [a, b] \in \mathbb{I} \mathbb{Q} \) is defined to be \( |I| = b - a \). Assuming \( a_1 \leq a_2 \), we define the distance between two intervals as

\[
\text{Dis}([a_1, b_1], [a_2, b_2]) = \begin{cases} 
  a_2 - b_1, & \text{if } [a_1, b_1] \cap [a_2, b_2] = \emptyset, \\
  0, & \text{otherwise}.
\end{cases}
\]
A pair of intervals $⟨I, J⟩$ is called a complex interval, which represents a rectangle in the complex plane. A complex number $(α, β) = α + βi$ (i.e., $i^2 = −1$) is said to be in a complex interval $⟨I, J⟩$ if $α ∈ I$ and $β ∈ J$. The length of a complex interval $⟨I, J⟩$ is defined to be $|⟨I, J⟩| = \max\{|I|, |J|\}$. We define the distance between two complex intervals as

$$\text{Dis}(⟨[a_1, b_1], [p_1, q_1]⟩, ⟨[a_2, b_2], [p_2, q_2]⟩) = \max\{\text{Dis}([a_1, b_1], [a_2, b_2]), \text{Dis}([p_1, q_1], [p_2, q_2])\}. \quad (16)$$

A set $S$ of disjoint complex intervals is called isolation intervals of $T(x) = 0$ if each interval in $S$ contains only one root of $T(x) = 0$ and each root of $T(x) = 0$ is contained in one interval in $S$. Methods to isolate the complex roots of a univariate polynomial equation are given in [3, 18, 22, 23].

Let $\mathbb{C}$ denote the set of complex intervals. An element $⟨I_1^P, I_1^T⟩ × · · · × ⟨I_n^P, I_n^T⟩$ in $\mathbb{C}^n$ is called a complex box. A set $S$ of isolation boxes for a zero dimensional polynomial system $P$ in $\mathbb{Q}[x_1, \ldots, x_n]$ is a set of disjoint complex boxes in $\mathbb{C}^n$ such that each box in $S$ contains only one root of $P = 0$ and each root of $P = 0$ is in one of the boxes. Furthermore, if each box $B = ⟨I_1^P, I_1^T⟩ × · · · × ⟨I_n^P, I_n^T⟩$ in $S$ satisfies $\max\{|I_1^P|, |I_1^T|\} ≤ ϵ$, then $S$ is called an $ϵ$-isolation boxes of $P = 0$. The aim of this paper is to compute a set of $ϵ$-isolation boxes for a zero-dimensional polynomial system $P$.

3.2. Gröbner basis and computation of $r_i$ and $T_i(x)$

In this subsection, we will show how to use Gröbner basis to compute $r_i$ defined in (6) and $T_i(x)$ defined in (8) supposing the parameters $s_i$ are given.

Let $P ⊂ \mathbb{Q}[x_1, \ldots, x_n]$ be a zero-dimensional polynomial system. Then $A = \mathbb{Q}[x_1, \ldots, x_n]/(P)$ is a finite dimensional linear space over $\mathbb{Q}$. Let $G$ be a Gröbner basis of $P$ with any ordering. Then the set of remainder monomials

$$B = \{x_1^{t_1} \cdots x_n^{t_n} | x_1^{t_1} \cdots x_n^{t_n} \text{ is not divisible by the leading term of any element of } G\}$$

forms a basis of $A$ as a linear space over $\mathbb{Q}$, where $t_i$ are non-negative integers.

Let $f ∈ \mathbb{Q}[x_1, \ldots, x_n]$. Then $f$ gives a multiplication map

$$M_f : A → A$$

defined by $M_f(p) = fp$ for $p ∈ A$. It is clear that $M_f$ is a linear map. We can construct the matrix representation for $M_f$ from $B$ and $G$. The following theorem is a basic property for $M_f$ [16].

**Theorem 7** (Stickelberger’s Theorem). Assume that $P ⊂ \mathbb{Q}[x_1, \ldots, x_n]$ has a finite positive number of solutions over $\mathbb{C}$. The eigenvalues of $M_f$ are the values of $f$ at the roots of $P = 0$ over $\mathbb{C}$ with respect to multiplicities of the roots of $P = 0$.

Let $s_i$ be rational numbers satisfying (7) and

$$F_i = P ∪ \{x − x_1 − s_1x_2 − · · · − s_{i−1}x_i\}.$$  

We can compute $g_i(x_i)$ and $T_i(x)$ such that

$$(g_i(x_i)) = \mathbb{Q}[x_i] ∩ (P) \text{ and } (T_i(x)) = \mathbb{Q}[x] ∩ (F_i). \quad (17)$$

In fact, we can construct the matrices for $M_{x_i}$ and $M_x$ based on $B$ and $G$, and $g_i(x_i)$ and $T_i(x)$ are the minimal polynomials for $M_{x_i}$ and $M_x$, respectively (See reference [18]). Note that we can also use the method introduced in reference [17] to compute $g_i(x_i), T_i(x)$. 

From Theorem 7 and (a) of Lemma 4, the $i$-th coordinates of all the roots of $P = 0$ are roots of $g_i(x_i) = 0$, and all the possible values of $x = \sum_{j=1}^{i-1} s_1 \cdots s_{j-1} x_j$ on the roots of $P = 0$ are roots of $T_i(x) = 0$.

Now we show how to estimate $r_i$ defined in (6). At first, compute $(g_i(x_i)) = (P) \cap \mathbb{Q}[x_i]$. Then we have the following result.

**Lemma 8.** Use the notations introduced before. Then

$$r_i = 2 \max \{\text{RB}(g_i(x_i))\} \quad (18)$$

satisfies the condition (6), where $\text{RB}(g)$ is the root bound of a univariate polynomial equation $g = 0$.

**Proof.** The lemma is obvious since for any root $(\xi_1, \ldots, \xi_i) \in V_C(I_i)$, $\xi_i$ is a root of $g_i(x_i) = 0$.

### 3.3. Theoretical preparations for the algorithm

In this subsection, we will outline an algorithm to compute an LUR for $P$ and to isolate the roots of $P = 0$ under a given precision $\epsilon$. The algorithm is based on an interval version of Theorem 2.

We define the isolation boxes for an LUR defined in (2) as:

$$\{B_1 \times B_2 - B_1 \times \cdots \times B_n - B_{n-1} \times S_1 \cdots S_{i-1} | B_i \in B_i, \text{Dis}(B_{i+1}, B_i) < \rho_i/2, 1 \leq i \leq n - 1\} \quad (19)$$

where $B_i$ is a set of isolation boxes for the complex roots of $T_i(x) = 0$ and $\rho_i = s_1 \cdots s_{i-1} d_i$.

In Theorem 16 to be proved below, we will give criteria under which the isolation boxes for $P$ are the isolation boxes of an LUR.

Let $P \subset \mathbb{Q}[x_1, \ldots, x_n]$ be a zero-dimensional polynomial system. We will compute an LUR for $P$ and a set of $\epsilon$-isolation boxes for the roots of $P = 0$ inductively.

At first, consider $i = 1$. We compute $T_1(x)$ as defined in equation (17). Let $B_1$ be a set of isolation intervals for the complex roots of $T_1(x) = 0$. Then, we can set $d_1$ to be the minimal distance between any two intervals in $B_1$.

For $i$ from 1 to $n - 1$, assuming that we have computed

- An LUR $(T_1(x), \ldots, T_i(x), s_i, d_j, j = 1, \ldots, i - 1)$ for $I_i$.
- A set of $\epsilon$-isolation boxes for $I_i$.
- The parameter $d_i$.

We will show how to compute $r_{i+1}$, $s_i$, $T_{i+1}(x)$, $d_{i+1}$, and a set of $\epsilon$-isolation boxes of the roots of $I_{i+1} = 0$. The procedure consists of three steps.

**Step 1.** We will compute $r_{i+1}$, $s_i$ as introduced in (6) and (7). With $s_i$, we can compute $T_{i+1}(x)$ as defined in (17).

Here $r_{i+1}$ can be computed with the method in Lemma 8. Note that $d_i$ is known from the induction hypotheses. Then we can choose a rational number $s_i$ such that condition (7) is valid. Finally, $T_{i+1}(x)$ can be computed with the methods mentioned below equation (17).
Lemma 9. We have ξ = (ξ₁, ..., ξₖ, ξₖ₊₁) such that ξₖ₊₁ is a root of \( \mathcal{T}_{k+1} = 0 \). Let ξ = (ξ₁, ..., ξₖ) be a root of \( \mathcal{T}_{k} = 0 \). We are going to find the roots of \( \mathcal{T}_{k+1} = 0 \) “lifted” from ξ, that is, roots of the form

\[
ξ_j = (ξ₁, ..., ξₖ, ξₖ₊₁, j = 1, ..., m.
\]

To do that, we need only to find a set of isolation intervals for ξₖ₊₁ than \( η \), since we already have an \( ε \)-box for ξ.

Let

\[
η = ξ₁ + s₁ξ₂ + ⋯ + sₖsₖ₋₁ξₖ.
\]

Then, η is a root of \( T_i(x) = 0 \). By (b) of Lemma 4 the roots \( θ_j \) of \( T_{i+1}(x) = 0 \) correspond to ξₖ are

\[
θ_j = η + s₁s₂ξₖ₊₁, j = 1, ..., m.
\]

We have

Lemma 9. Let \( I_i = [a, b], [c, d] \) be an isolation interval for the root \( η \) of \( T_i(x) = 0 \) such that \( |I_i| < 4/ₙ \rho_i \) where \( ρ_i = s₁s₂sₖ₋₁sₖ \). Then all \( θ_j \) in (21) are in the following complex interval

\[
I_{θ_j} = [(a - ρ_i/2, b + ρ_i/2, (c - ρ_i/2, d + ρ_i/2)).
\]

Furthermore, the intervals \( I_{θ_j} \) are disjoint for all roots \( η \) of \( T_i(x) = 0 \).

Proof. In Figure 2, let square \( ABCD \) be \( S_{θ_i} = \{ θ ∈ \mathbb{C} ||θ - η_i| < ρ_i \} \) and \( A₁B₁C₁D₁ = \{ θ ∈ \mathbb{C} ||θ - η_i| < ρ_i/2 \} \). By equation (14), we know \( |θ_j - η_i| < 4/ₙ \rho_i \). So, \( θ_j \) is inside \( A₁B₁C₁D₁ \). Let rectangle \( A₂B₂C₂D₂ \) be the complex interval \( I_i \) and rectangle \( A₃B₃C₃D₃ \) the complex interval \( I_{θ_j} \), which is obtained by adding \( ρ_i/2 \) in each direction of the rectangle \( A₃B₃C₃D₃ \). Then, \( I_{θ_j} \) contains \( A₁B₁C₁D₁ \) and hence \( θ_j \) is inside \( I_{θ_j} \).

For any \( θ ∈ I_{θ_j} \), we have \( |θ - η_i| ≤ |θ - P| \) where \( P \) is one of the points \( A₂, B₂, C₂, D₂ \) to make \( |θ - P| \) maximal. It is clear that \( |θ - P| ≤ ρ_i/2 + |I_i| = 2ₙ \rho_i \). So, \( ∀θ ∈ I_{θ_j}, |θ - η_i| ≤ 4ₙ \rho_i. \)

Since \( S_{θ_i} \) is the set of complex numbers satisfying \( |θ - η_i| < ρ_i \), we have \( I_{θ_j} ⊂ S_{θ_i} \). By (c) of Lemma 4, \( S_{θ_i} \) are disjoint for all roots of \( T_i(x) = 0 \). Then \( I_{θ_j} \) are disjoint for all roots of \( T_i(x) = 0 \) too.

The following lemma shows what is the precision needed to isolate the roots of \( T_{i+1}(x) = 0 \) in order for the isolation boxes to be contained in some \( I_{θ_j} \). It can be seen as an effective version of the fact \( η_{i+1} ∈ S_{θ_i} \) proved in Lemma 3.

Lemma 10. Use the notations introduced in Lemma 9. Let \( \{B_j, j = 1, ..., m\} \) be a set of \( 1/ₙ ρ_i \)-isolation boxes for the roots \( θ_j, j = 1, ..., m \) of \( T_{i+1}(x) = 0 \). Then, for all \( j \)

\[
B_j ⊂ I_{θ_j} \quad \text{and} \quad \text{Dis}(B_j, I_i) < ρ_i/2.
\]
Lemma 11. With the notations introduced above, if the following conditions

\[
(q_j - p_j) + (b - a) < s_1 \cdots s_i \epsilon, \quad (h_j - g_j) + (d - c) < s_1 \cdots s_i \epsilon
\]

\[
S_{\eta_i} = \min_{1 \leq k \neq j \leq m} \text{Dis}(\langle p_k, q_k, [g_k, h_k] \rangle, \langle p_j, q_j, [g_j, h_j] \rangle) > \max\{b - a, d - c\}
\]

are valid, then \(J_{i+1,j}\) defined in (24) are \(\epsilon\)-isolation intervals of \(\xi_{i+1,j}\) in equation (20).

Proof. It is clear that condition (25) is used to ensure the precision: \(|J_{i+1,j}| < \epsilon\).

We consider (26) below. Assume that \(J_{i+1,j}, J_{i+1,k}(1 \leq k \neq j \leq m)\) are any two intervals defined in (24) for the \((i+1)\)-th coordinates of the roots \((\xi_1, \ldots, \xi_i, \xi_{i+1,j}), (\xi_1, \ldots, \xi_i, \xi_{i+1,k})\) of \(I_{i+1} = 0\), respectively. Since we have derived the \(\epsilon\)-isolation boxes for the roots of \(I_i = 0\), we need only to ensure that the intervals of the \((i+1)\)-th coordinates of the roots of \(I_{i+1} = 0\) lifted from a fixed root of \(I_i = 0\) are isolation intervals. That is, to show \(\text{Dis}(J_{i+1,j}, J_{i+1,k}) > 0\).

Assume that \(K_j = \langle p_j, q_j, [g_j, h_j] \rangle\) and \(K_k = \langle p_k, q_k, [g_k, h_k] \rangle\) are the isolation intervals of the roots \(\eta_j, \eta_k\) of \(T_{i+1}(x) = 0\). Here \(\eta_j, \eta_k\) correspond to \((\xi_1, \ldots, \xi_i, \xi_{i+1,j}), \ldots, (\xi_1, \ldots, \xi_i, \xi_{i+1,k})\).
Lemma 14. Let \( p_j \leq p_k, g_j \leq g_k \). Then we have
\[
\text{Dis}(J_{i+1,j}, J_{i+1,k}) = \max_{s_1 \cdots s_i} \{\text{Dis}([p_j - b, q_j - a], [p_k - b, q_k - a]), \text{Dis}([g_j - d, h_j - c], [g_k - d, h_k - c])\},
\]
and
\[
L_1 = \text{Dis}([p_j - b, q_j - a], [p_k - b, q_k - a]) = \begin{cases} (p_k - q_j) - (b - a), & \text{if } (p_k - q_j) - (b - a) > 0, \\ 0, & \text{otherwise}, \end{cases}
\]
\[
L_2 = \text{Dis}([g_j - d, h_j - c], [g_k - d, h_k - c]) = \begin{cases} (g_k - h_j) - (d - c), & \text{if } (g_k - h_j) - (d - c) > 0, \\ 0, & \text{otherwise}. \end{cases}
\]

\( K_j \) and \( K_k \) are disjoint since they are isolation intervals of \( T_{i+1}(x) = 0 \). So
\[
\text{Dis}(K_j, K_k) = \max \{p_k - q_j, g_k - h_j\} > 0.
\]
It is clear that \( \text{Dis}(J_{i+1,j}, J_{i+1,k}) > 0 \) if \( L_1 > 0 \) or \( L_2 > 0 \). Then we conclude if inequality (26) is true, then \( \text{Dis}(J_{i+1,j}, J_{i+1,k}) > 0 \). This proves the lemma.

Geometrically, \( S_\eta \) is the separation bound for the roots of \( T_{i+1}(x) = 0 \) corresponds to those roots of \( I_{i+1} \) lifted from the root of \( I_i = 0 \) corresponding to the root \( \eta \) of \( T_I(x) = 0 \).

Remark 12. Note that in (26), we obtain \( I_i = ([a, b], [c, d]) \) first and \( K_j = ([p_j, q_j], [g_j, h_j]) \) later. We will refine the isolation interval \( I_i \) of \( T_i(x) = 0 \) such that inequality (26) is true. After the refinement, all other conditions are still valid. We need to do this kind of refinement only once.

As a consequence of the above lemma, we have

Corollary 13. Let \( B \) be an \( \epsilon \)-isolation box for the root \( \xi \) of \( I_i = 0 \) and \( J_{i+1,j} \) defined in (24). If (25), (26) are valid, then \( B \times J_{i+1,j}, j = 1, \ldots, m \) are \( \epsilon \)-isolation boxes for the roots \( \rho_j \) of \( I_{i+1} = 0 \), which are lifted from \( \xi \).

Step 3. We will show how to compute \( d_{i+1} \) from the isolation intervals of \( T_{i+1}(x) = 0 \).

Lemma 14. Let
\[
d_{i+1} = \min \left\{ \frac{S_{i+1}}{2s_1 \cdots s_i}, \frac{d_i}{2s_i} \right\},
\]
where \( S_{i+1} \) is the minimal distance between any two isolation intervals of \( T_{i+1}(x) = 0 \). Then \( d_{i+1} \) satisfies conditions (5).

Proof. Let \( \theta_j \) and \( \theta_k \) be two different roots of \( T_{i+1}(x) = 0 \) defined in (21). Then we have
\[
\xi_{i+1,j} - \xi_{i+1,k} = \frac{\theta_j - \theta_k}{s_1 \cdots s_i}.
\]
Therefore, \( D_{i+1} = \min_{\theta \in V_i(T_{i+1}(x))} \left\{ \frac{S_\eta}{2s_i} \right\} \) is the parameter defined in (4), where \( S_\eta \) is determined as in (26). It is clear that \( D_{i+1} \) is not larger than \( S_{i+1} \) which is the minimal distance between any two isolation intervals of \( T_{i+1}(x) = 0 \). Then, the first condition in (5) is satisfied. In order for the second condition in (5) to be satisfied, we also require \( d_{i+1} \leq \frac{d_i}{2s_i} \). So the lemma is proved.
We can summarize the result as the following theorem which is an interval version of Theorem 2.

**Theorem 15.** Let (2) be an LUR such that $d_i$, $r_i$, and $s_i$ satisfy (27), (6), and (7) respectively, $B_i$ the $\epsilon_i$-isolation boxes for the roots of $T_i(x) = 0$, and $S_i = \min\{\text{Dis}(B_1, B_2) | B_1, B_2 \in B_i, B_1 \neq B_2\}$. If

$$
\epsilon_1 \leq \epsilon, \epsilon_i + \epsilon_{i+1} \leq s_1 \cdots s_i \epsilon, \epsilon_i \leq \frac{\rho_i}{4}, \epsilon_{i+1} \leq \frac{\rho_i}{4}, \epsilon_i \leq S_{i+1},
$$

(28)

where $\rho_i = s_1 \cdots s_{i-1} d_{i}$, then (19) is a set of $\epsilon$-isolation boxes for $\mathcal{P}$.

**Proof.** We first explain the functions of the inequalities in (28). The first two inequalities in (28) are introduced in (25) to ensure the $\epsilon$ precision for the isolation boxes. The third inequality in (28) is introduced in Lemma 9 to ensure $\theta_j \in I_i I_i$ and $I_i I_i$ are disjoint. The fourth inequality is introduced in Lemma 10 to ensure the isolation intervals of the roots of $T_{i+1}(x) = 0$ are inside their corresponding interval $I_i I_i$. The last inequality is introduced in (26) to ensure the recovered isolation boxes of $\mathcal{P}$ are disjoint.

Now the theorem is a consequence of Corollary 13. Here, we give the explicit expression for the isolation boxes. The expression for interval $J_{i+1,j}$ in (24) is directly given. The matching condition $\text{Dis}(B_{i+1}, B_i) < \rho_i/2$ is from condition (23).

We have the following effective version of Theorems 2 and 15 by giving an explicit formula for $\epsilon_i$.

**Theorem 16.** Using the same notations as Theorem 15. Let $\epsilon$ be the given precision to isolate the roots of $\mathcal{P}$. Let

$$
\epsilon_1 = \min\{\epsilon, \frac{s_1 \epsilon}{2}, \frac{d_1}{4}, S_2\},
\epsilon_i = \min\{\frac{s_1 \cdots s_{i-1} \epsilon}{2}, \frac{s_1 \cdots s_i \epsilon}{2}, \frac{s_1 \cdots s_{i-1} d_i}{4}, \frac{s_1 \cdots s_{i-2} d_{i-1}}{4}, S_{i+1}\},
$$

(29)

where $i = 2, \ldots, n$, $s_0 = 1$, $s_n = 1$, $S_{n+1} = +\infty$. If we isolate the roots of $T_i(x) = 0$ with precision $\epsilon_i$, then (19) is a set of $\epsilon$-isolation boxes for $\mathcal{P} = 0$.

**Proof.** By (29), we have $\epsilon_i \leq \frac{s_1 \cdots s_{i-1} \epsilon}{2} + \epsilon_{i+1} \leq \frac{s_1 \cdots s_i \epsilon}{2} + \frac{s_1 \cdots s_{i-1} d_i}{4} + \frac{s_1 \cdots s_{i-2} d_{i-1}}{4} + S_{i+1}$. Then the second inequality in (28), $\epsilon_i + \epsilon_{i+1} \leq s_1 \cdots s_i \epsilon$, is valid. All other inequalities in (28) are clearly satisfied and the theorem is proved.

We can also compute the multiplicities of the roots with the LUR algorithm.

**Corollary 17.** If we compute the last univariate polynomial $T_n(x)$ in the LUR as the characteristic polynomial of $M_x$, then the multiplicities of the roots of $\mathcal{P} = 0$ are the multiplicities of the corresponding roots of $T_n(x) = 0$.

**Proof.** By (a) of Lemma 4, $x = x_1 + s_1 x_2 + \cdots + s_1 \cdots s_{n-1} x_n$ is a separating element. By Theorem 7, the characteristic polynomial of $M_x$ keeps the multiplicities of the roots of the system. The corollary is proved.
3.4. Algorithm

Now, we can give the full algorithm based on LUR.

Algorithm 1. The input is a zero dimensional polynomial system \( \mathcal{P} = \{P_1, \ldots, P_t\} \) in \( \mathbb{Q}[x_1, \ldots, x_n] \) and a positive rational number \( \epsilon \). The output is an LUR for \( \mathcal{P} \) and a set of \( \epsilon \)-isolation boxes for the roots of \( \mathcal{P} = 0 \).

S1 Compute a Gröbner basis \( \mathcal{G} \) of \( \mathcal{P} \) with the graded reverse lexicographic order and a monomial basis \( \mathbf{B} \) for linear space \( \mathcal{A} = \mathbb{Q}[x_1, \ldots, x_n]/(\mathcal{P}) \) over \( \mathbb{Q} \).

S2 Compute \( T_1(x) \) as defined in (17) with the method given in Section 3.2; compute a set of \( \epsilon \)-isolation boxes \( \mathcal{B}_1 \) for the complex roots of \( T_1(x) = 0 \); set \( d_1 = \min\{\text{Dis}(\mathcal{B}_1, \mathcal{B}_2) \mid \mathcal{B}_1, \mathcal{B}_2 \in \mathcal{B}_1, \mathcal{B}_1 \neq \mathcal{B}_2\} \).

S3 For \( i = 1, \ldots, n - 1 \), do steps S4-S9; output the set of boxes (19).

S4 Compute \( r_{i+1} \) with the method in Lemma 8. Select a rational number \( s_i \) such that condition (7) is valid.

S5 Compute \( T_{i+1}(x) \) as defined in (17) with the method given in Section 3.2.

S6 Set \( \rho_i = s_1 \cdot \ldots \cdot s_{i-1} d_i \) and compute a set of \( \frac{1}{4} \rho_i \)-isolation boxes \( \mathcal{B}_{i+1} \) for the complex roots of \( T_{i+1}(x) = 0 \)

S7 Set \( S_{i+1} = \min\{\text{Dis}(\mathcal{B}_1, \mathcal{B}_2) \mid \mathcal{B}_1, \mathcal{B}_2 \in \mathcal{B}_{i+1}, \mathcal{B}_1 \neq \mathcal{B}_2\} \).

S8 Compute \( d_{i+1} \) with formula (27).

S9 Compute \( \epsilon_i \) with formula (29); refine the isolation boxes \( \mathcal{B}_i \) of \( T_i(x) = 0 \) with precision \( \epsilon_i \); still denote the isolation boxes as \( \mathcal{B}_i \).

Remark 18. From Lemma 9, the roots of \( T_{i+1}(x) = 0 \) are in the rectangle \( \mathbb{I}_{I_i} \). So, we need only to isolate the roots of \( T_i(x) = 0 \) inside these rectangles. This property is very useful in practice, see Figure 1 for an illustration.

4. Examples

In this section, we will give some examples to illustrate our method.

We first use the following example to show how to isolate the roots of a system with our method. Note that with an LUR, we can also use floating point numbers to compute the roots of \( \mathcal{P} = 0 \) if the floating point number can provide the required precision as shown in the following example.

Example 19. Consider the system \( \mathcal{P} := [x^2 + y^2 + z^2 - 3, x^2 + 2y^2 - 3z + 1, x + y - z] \).

The coordinate order is \((x, y, z)\).

The Gröbner basis \( \mathcal{G} \) with the graded reverse lexicographic order \( z > y > x \) of \( \mathcal{P} \) is:

\[-x - y + z, x^2 + 2yx + 3x - 4 + 3y, -3x + x^2 + 1 - 3y + 2y^2, 6x^3 - 30 + 9x^2 + 25y + 5x].\]

The leading monomials of the basis are \( \{z, xy, y^2, x^3\} \). So the monomial basis of the quotient algebra \( \mathcal{A} = \mathbb{Q}[x_1, \ldots, x_n]/(\mathcal{P}) \) is \( \mathbf{B} = [1, x, y, x^2] \).
Let $t = x$, we can compute:

$$M_t = \begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
2 & -3/2 & -3/2 & -1/2 \\
5 & -5/6 & -29/6 & -3/2
\end{bmatrix}.$$  

The minimal polynomial of $M_t$ is

$$T_1(t) = 5 - 60t + 6t^2 + 18t^3 + 6t^4.$$  

Compute its complex roots with the function “Analytic” in Maple package [RootFinding], we obtain

$$R_1 = \{-2.22081423399575 - 1.53519779646152i, -2.22081423399575 + 1.53519779646152i, 0.0842270424726020, 1.35740142551890\}.$$  

Computing the roots distance with formula (16), we obtain $d_1 \leq 0.6365871918$. We can set $d_1 = \frac{1}{2}$.

In a similar way, we compute $M_y$ and its minimal polynomial $g_2(y) = -29 - 66y + 60y^2 + 12y^4$. The root bound of $g_2(y)$ is 3. So we have $r_2 = 6$. Since $\frac{d_1}{r_2} = \frac{1}{12}$, we set

$$s_1 = \frac{1}{20}.$$  

Let $t = x + s_1 y$. We can compute a matrix $M_t$ and its minimal polynomial

$$T_2(t) = 863337 - 6119640t + 360000t^2 + 1920000t^3 + 640000t^4.$$  

Computing its complex roots, we have

$$R_2 = \{-2.24194942371773 - 1.41342395552762i, -2.24194942371773 + 1.41342395552762i, 0.143249906267126, 1.34064894116850\}.$$  

Computing the minimal distance between any two roots, we have $S_2 = 0.5986995174$. From equation (27), we can obtain

$$d_2 = \min\left\{\frac{S_2}{2s_1}, \frac{d_1}{2s_1}\right\} = 5.$$  

Compute $M_z$ and its minimal polynomial $g_3(z) = 121 - 132z - 36z^2 + 36z^3 + 12z^4$. Then the root bound of $g_3(z)$ is 5. We have $r_3 = 10$. We can set

$$s_2 = \frac{1}{2} \leq \frac{d_2}{r_3} = \frac{1}{2}.$$  

Let $t = x + s_1 y + s_1 s_2 z$. Compute $M_t$ and its minimal polynomial

$$T_3(t) = 53294617 - 309903360t + 11884800t^2 + 94464000t^3 + 30720000t^4.$$
Computing its complex roots, we have

\[ R_3 = [-2.30803737442857 - 1.39091697997219i, -2.30803737442857 + 1.39091697997219i, 0.174867014226204, 1.36620773463121]. \]

We use \( R_1[i] \) to represent the \( i \)-th element of \( R_1 \). \( R_2[i] \), \( R_3[i] \) are similarly defined. Since \( R_2[1] - R_1[1] = -0.021135190 + 0.121773840i \) and the absolute values of its real part and imaginary part are less than 1/2, \( (R_1[1], \frac{R_2[1] - R_1[1]}{s_1}) \) is a root of \( \mathcal{P} \cap \mathbb{Q} [x, y] \). But \( R_2[2] - R_1[1] = -0.021135190 + 2.948621752i \) and its imaginary part is larger than 1/2. Then \( R_2[2] \) does not correspond to \( R_1[1] \). \( R_3[1] - R_2[1] = -0.066087950 + 0.022506976i \) and the absolute values of its real part and imaginary part are less than 1/4, so

\[
\begin{align*}
(R_1[1], \frac{R_2[1] - R_1[1]}{s_1}, \frac{R_3[1] - R_2[1]}{s_1s_2}) \\
= \left( -2.22081423399575 - 1.535197797646152i, -0.42270380 + 2.43547680i, \\
-2.64351800 + 0.90027904i \right)
\end{align*}
\]

is a root of \( \mathcal{P} = 0 \). In a similar way, we can find all other complex roots of \( \mathcal{P} = 0 \). And from Theorem 16, we can set \( \epsilon_1 = \frac{1}{30} \epsilon, \epsilon_2 = \epsilon_3 = \frac{1}{80} \epsilon \), where \( \epsilon \) is the given precision. So if we refine the roots of \( T_i(t) = 0 \) to five digits, we can obtain the roots of \( \mathcal{P} = 0 \) with three digits.

We also obtain an LUR for \( \mathcal{P} \) as follows:

\[ \llbracket [T_1(t), T_2(t), T_3(t)], [s_1, s_2], [d_1, d_2] \rrbracket. \]

The roots of \( \mathcal{P} = 0 \) are:

\[ \llbracket [\alpha, 20(\beta - \alpha), 40(\gamma - \beta)] | T_1(\alpha) = 0, T_2(\beta) = 0, T_3(\gamma) = 0, |\beta - \alpha| < 1/2, |\gamma - \beta| < 1/4 \rrbracket. \]

Assuming that the final precision for the real roots of the system is \( \epsilon = 1/2^{10} \) and isolating the real roots of \( T_i(t) = 0 \) with precision \( \epsilon_1 = \frac{1}{40} \epsilon, \epsilon_2 = \epsilon_3 = \frac{1}{80} \epsilon \), respectively, we can obtain the following two real roots of \( \mathcal{P} = 0 \) with the given precision:

\[
\begin{bmatrix}
5519 & 345 & 38695 \\
65536 & 4096 & 32768
\end{bmatrix} \times \begin{bmatrix}
4835 & 38695 & 20715 & 20725 \\
4906 & 32768 & 65536
\end{bmatrix} \times \begin{bmatrix}
44179 & 88959 & -10985 & -5485 \\
32768 & 16384 & 16384
\end{bmatrix} \times \begin{bmatrix}
-16745 & -16755 & 16745 & 16755
\end{bmatrix}
\]

In the next example, we will compare our method with RUR [20].

**Example 20.** Consider the following example from paper [20]. \( \mathcal{P} := [24 uz - u^2 - z^2 - u^2 z^2 - 13, 24 yz - y^2 - z^2 - y^2 z^2 - 13, 24 uy - u^2 - y^2 - u^2 y^2 - 13] \). The coordinate order is \( (u, y, z) \).

The RUR is as follows.

\[ f(x) = 0, \quad u = \frac{g(u, x)}{g(1, x)}, \quad y = \frac{g(y, x)}{g(1, x)}, \quad z = \frac{g(z, x)}{g(1, x)} \]

where
\[ f(x) = x^{16} - 5656 x^{14} + 12508972 x^{12} - 14213402440 x^{10} + 9020869309270 x^8 \\
-3216081009505000 x^6 + 606833014754230732 x^4 \\
-51316296630855044152 x^2 + 1068130551224672624689, \]

\[ g(1, x) = x^{15} + 4949 x^{13} + 3881792 x^{11} + 8883376525 x^9 + 4610434654635 x^7 \\
-1206030378564375 x^5 + 151708253688557683 x^3 - 6414537078856880519 x, \]

\[ g(u, x) = 116 x^{14} + 483592 x^{12} + 784226868 x^{10} - 634062241592 x^8 \\
+ 270086313707548 x^6 - 5835557948017944 x^4 + 5520988105236180668 x^2 \\
-131448117382500870952, \]

\[ g(y, x) = 86 x^{14} - 418870 x^{12} + 759804846 x^{10} - 670485664238 x^8 + 307445009725282 x^6 \\
-71012402366579778 x^4 + 7099657810552674458 x^2 - 16819096202566563226, \]

\[ g(z, x) = 71 x^{14} - 355135 x^{12} + 673508751 x^{10} - 633214359791 x^8 + 314815356569869 x^6 \\
-79677638700441717 x^4 + 8618491509948092045 x^2 - 205956089289536014429. \]

An LUR of \( P \) is as follows:

\[ [[[T_1(t), T_2(t), T_3(t)], [s_1, s_2], [d_1, d_2]] = [[[T_1(t), T_2(t), T_3(t)], [1/200, 1/15], [0.2237374734, 2.146554200]], \]

where

\[ T_1(t) = 169 - 1820 t^2 + 2622 t^4 - 140 t^6 + t^8, \]

\[ T_2(t) = 1203455627604920308981441166197 - 133523438810776274535699687120000 t^2 \\
+334257305564156882138712000000000 t^4 - 25645697161208533936000000000000000 t^6 \\
+236290055416704000000000000000000000 t^8 - 66528890880000000000000000000000000 t^{10} \\
+40960000000000000000000000000000000 t^{12}, \]

\[ T_3(t) = 398658124842757922827990174525891734024598098970801 \\
-50570450167758092657427376502856962389191187181687500 t^2 \\
+183065684629027476820786566268083072181886699218750 t^4 \\
-2697101627430799183857508494453342793235778808593750 t^6 \\
+1556359191027111342350511466840399783573150634765625 t^8 \\
-193641915506769319996114502638578414916992187500000 t^{10} \\
+9419063421770692625813931126730346679687500000000 t^{12} \\
-18501481584396628075008392333948347750000000000000 t^{14} \\
+1002259575761854854850087890625000000000000000 t^{16}. \]

The roots of \( P \) are: \( \{(u, y, z) = (\alpha, 200(\beta - \alpha), 3000(\gamma - \beta)) | T_1(\alpha) = 0, T_2(\beta) = 0, T_3(\gamma) = 0, |\beta - \alpha| < 0.2237374734, |\gamma - \beta| < 0.01073277100\} \).
5. Conclusion

We give a new representation, LUR, for the roots of a zero-dimensional polynomial system \( P \) and propose an algorithm to isolate the roots of \( P \) under a given precision \( \epsilon \). For the LUR, the roots of the system are represented as a linear combination of the roots of some univariate polynomial equations. The main advantage of LUR is that precision control of the roots of the system is much clearer.

The main drawback of the LUR method is that when the parameters \( s_i \) becomes very small, the coefficients of \( T_i(t) \) could become very large, which will slow down the algorithm. To improve the efficiency of the LUR algorithm is our future work.
