We find a parametrically light dilaton in special confining theories in three dimensions. Their duals form what we call a scion of solutions to the supergravity associated with the large-$N$ limit of the Coulomb branch of the $\mathcal{N} = 4$ Super-Yang-Mills theory. The supergravity description contains one scalar with bulk mass that saturates the Breitenlohner-Freedman unitarity bound. The new solutions are defined within supergravity, they break supersymmetry and scale invariance, and one dimension is compactified on a shrinking circle, yet they are completely regular. An approximate dilaton appears in the spectrum of background fluctuations (or composite states in the confining theory), and becomes parametrically light along a metastable portion of the scion of new supergravity solutions, in close proximity of a tachyonic instability. A first-order phase transition separates stable backgrounds, for which the approximate dilaton is not parametrically light, from metastable and unstable backgrounds, for which the dilaton becomes parametrically light, and eventually tachyonic.

DOI: 10.1103/PhysRevD.104.046003

I. INTRODUCTION

In Refs. [1,2], we proposed a mechanism giving rise to an approximate dilaton in the spectrum of composite states of special classes of confining theories, in four dimensions, that admit a higher-dimensional gravity dual. We provided two explicit, calculable realizations of this mechanism, which generalizes the ideas proposed in Ref. [3] (and is further critically discussed in Refs. [4–6]). We considered non-anti-de Sitter (AdS) gravity backgrounds in proximity of classical instabilities—generalizing the proximity to the Breitenlohner-Freedman (BF) unitarity bound [7] in AdS space. An approximate dilaton (a scalar particle coupling to the trace of the energy-momentum tensor) emerges along special branches of supergravity solutions. Portions of the branches yield stable solutions, while complementary ones describe metastable or even unstable solutions. Moving in parameter space along the branch of solutions, the dilaton has finite mass for stable solutions, becomes parametrically light for metastable ones, and tachyonic for the unstable ones.

The analysis follows the prescriptions of gauge-gravity dualities [8–11], in the calculation of the free energy, via holographic renormalization [12–14], and of the spectrum of the bound states, via a convenient gauge-invariant formalism [15–19]. We adopt the holographic description of confinement, the calculation of Wilson loops [20–26], and the interpretation of singularities [27]. We restrict attention to well established supergravity theories (top-down holography). Ref. [1] studies the half-maximal supergravity in $D = 6$ dimensions, due to Romans [28–31] (see also Refs. [32–49]), compactified on a circle [50–53], while Ref. [2] considers the maximal supergravity in $D = 7$ dimensions [54–58], compactified on a two-torus [59,60]. In Refs. [1,2], we explored regions of the admissible parameter space overlooked in the earlier literature.

The significance of Refs. [1,2] extends beyond producing calculable examples of the ideas exposed in Refs. [3–6]. Recent years saw a resurgence of interest in the literature on the dilaton effective field theory (EFT) description of near-conformal, strongly coupled systems in four dimensions (see for instance Refs. [61–73]). The literature on the subject has a long history [74], including early attempts to explain the long distance behavior of Yang-Mills [75] and walking technicolor [76–78] theories. One motivation for the revival is the uncovering of a light scalar particle, possibly a dilaton, in special $SU(3)$ lattice gauge theories coupled to matter [79–90]. Previously, the study of simple bottom-up holographic models showed the emergence of a dilaton in special cases of theoretical relevance [91–105]. Even top-down holography provided supporting evidence for the existence of a light scalar in special confining theories [106–110] related to the conifold [111–117]. Furthermore, the distinctive features of the dilaton EFT...
The purpose of this paper is to exhibit a third example of this mechanism, but realized in a lower dimensional theory, in backgrounds that in the far UV approach an AdS geometry, with bulk scalar mass close to the BF bound. This hence highlights differences and similarities with other proposals for the origin of the dilaton. We study a particular truncation of the $\mathcal{N} = 8$ maximal supergravity theory in $D = 5$ dimensions, which is (loosely) associated with the Coulomb branch of $\mathcal{N} = 4$ super-Yang-Mills (SYM) theories. By introducing a relevant deformation, and compactifying one dimension on a circle, we build a scion\footnote{The dual of the Coulomb branch is sourced by a discrete distribution of displaced D3 branes; conversely the pure supergravity action and lift we borrow from the literature [134] leads to singular supersymmetric solutions. In view of this loose relation between supergravity theory and Coulomb branch, we refer to our new solutions, obtained by elaborating on the gravity theory, as forming a scion, rather than a branch, as a way to emphasize their hybrid nature.} of gravity backgrounds yielding a light dilaton and admitting an interpretation in terms of a field theory in three dimensions that confines. The scion provides a one-parameter family generalization of the gravity background occasionally denoted in the literature as QCD$_3$, and for which the spectrum of fluctuations is known [60].

The paper is organized as follows. We summarize in Sec. II the main features of the Coulomb branch, as well as the consistent truncation of maximal supergravity in $D = 5$ dimensions, its reduction to $D = 4$ dimensions, the lift to $D = 10$ type IIB supergravity, and the prescription for Wilson loops. Section III summarizes the classes of solutions we investigate in this paper: we present the UV and IR expansions, then compute curvature invariants and Wilson loops to characterize the solutions. We compute the spectrum of fluctuations for the solutions in Sec. IV, in the appropriate number of dimensions. In Sec. V we compare the free energies, to discuss the stability of the solutions. After the conclusions in Sec. VI, we supplement the material with Appendix A, summarizing known results for the supersymmetric solutions, and Appendix B, exhibiting asymptotic expansions of the fluctuations used in computing the spectra.

II. THE MODEL

The $\mathcal{N} = 8$ maximal supergravity in $D = 5$ dimensions [135–137] has played a central role in the history of gauge-gravity dualities. It descends from dimensional reduction of type IIB supergravity in $D = 10$ dimensions on the five-sphere $S^5$ [138,139]. It has recently been established that this is a consistent truncation [140,141], and the full uplift back to type IIB is known [141–143] (see also Refs. [134,144,145]). The gauge symmetry is $SO(6) \sim SU(4)$—capturing the isometries of $S^5$, and the R-symmetry of the dual field theory, respectively. The field content includes 42 real scalars that match $\mathcal{N} = 4$ field-theory operators on the basis of their transformation properties under $SU(4)$; the complex singlet $1_C$ corresponds to the holomorphic gauge coupling, the symmetric $10_C$ to the fermion masses, and the real 20$'$ to the matrix of squared masses for the scalars $X_i$, with $i = 1, \ldots, 6$ (see e.g., Sec. 2.2.5 of Ref. [11], or the introduction of Ref. [146]).

One of the background solutions of $D = 5$ maximal supergravity lifts in type IIB to the AdS$_5 \times S^5$ background geometry providing the weakly-coupled dual description of $\mathcal{N} = 4$ SYM with $SU(N)$ gauge group, in the (decoupling) limit of large $N$ and large ’t Hooft coupling [8]. The supergravity solution is also the appropriate decoupling limit of the configuration sourced by a stack of $N$ coincident D3 branes. Following Ref. [147] (see also Refs. [23,148,149]) we refer to the Coulomb branch as the space of inequivalent vacua of the $\mathcal{N} = 4$ theory that preserves 16 supercharges. The space is so called because away from its $SO(6)$-invariant configuration the gauge group of the field theory is partially higgsed, and the massless gauge bosons mediate Coulomb interactions.

In the language of extended objects in $D = 10$ dimensions, the literature identified multi-centred D3-brane solutions [23,147] with the moduli space of $\mathcal{N} = 4$ SYM, in the sense that points of the Coulomb branch are associated with distributions of the $N$ D3 branes over $\mathbb{R}^6$ (conveniently parametrized as a cone over the sphere $S^5$), accompanied by the higgsing of $SU(N)$. By taking $N \to \infty$, while introducing a continuous distribution of D3 branes, one might hope to recover a supergravity description of the Coulomb branch still within maximal $\mathcal{N} = 8$ supergravity in $D = 5$ dimensions. In fact, the resulting metrics satisfy the supergravity equations [147], but are singular (see for example the discussion after Eq. (3.12) of Ref. [150]). These solutions are captured by a consistent
truncation \[\text{[134,144,145]}\] that retains only the 20' scalars, dual to the symmetric and traceless operator
\[
20' \sim \left( \delta_{ij} \delta_{kl} - \frac{1}{6} \delta_{ij} \delta_{kl} \right) \text{Tr} X_i X_j.
\]

There are five subclasses of solutions that preserve \(SO(n) \times SO(6-n)\) subgroups of \(SO(6)\), with \(n = 1, \ldots, 5\) \[\text{[147]}\]. With abuse of language, the supersymmetric backgrounds of this type are referred to as the Coulomb branch, though such solutions are singular, and hence incomplete as gravity duals.

We further restrict our attention to the \(n = 2\) and the \(n = 4\) cases \[\text{[23]}\]. The spectrum of the \(n = 2\) case is quite peculiar: both the spin-zero and spin-two spectra have a gap and a cut opening above a finite value \[\text{[12,147,151-154]}\] (see also Refs. \[\text{[154,155]}\] for the spectra of vectors). The choices \(n = 2, 4\) are convenient also because they are both captured by one of the subtruncations of the theory in Ref. \[\text{[156]}\]—which retains only two scalars, one in the 20' and the 10', respectively (see also the discussions in Refs. \[\text{[157,158]}\]). Setting to zero the latter of the two scalars reduces the field content to just one scalar (\(\phi\) in our notation), and the lift to \(D = 10\) dimensions is comparatively simple.

The gravity descriptions for \(n = 2, 4\) are different; \(n\) is associated with the ball \(B^n\) inside the internal space (including the radial direction) over which one distributes the \(N\) D3 branes, and is then reflected in the Ramond fluxes in supergravity. We will identify two distinct classes of solutions to the supergravity equations, distinguished by the negative or positive sign of \(\phi\) at the end of space, which we associate with \(n = 2, 4\), respectively (see also the discussion at the end of Sec. 2 in Ref. \[\text{[134]}\]). We display the supersymmetric solutions and summarize their known properties in Appendix A.

We reconsider the system consisting of the scalar \(\phi\) coupled to gravity in \(D = 5\) dimensions, and describe more general classes of solutions with respect to the literature. These more general deformations break explicit supersymmetry and scale invariance, hence lifting the space of vacua, and modifying the spectrum of the theory. We focus on solutions that involve either of two possibilities.

(a) In Secs. III B and III C, we display singular domain wall solutions that generalize the supersymmetric ones while preserving Poincaré invariance in four dimensions. The dual field theory is deformed by mass terms, breaking supersymmetry, R-symmetry, and scale invariance. We compute the spectrum of fluctuations—which barring the singularity would be interpreted as bound states of the dual field theory in four dimensions—and the behavior of the quark-antiquark potential between static sources, generalizing the results of Ref. \[\text{[23]}\]. We discover one new special subclass of mildly singular solutions, that yield a long-distance potential \(E_W \propto 1/L^2\) persisting up to infinite separation \(L\).

(b) In Sec. III D, we identify background solutions for which one of the dimensions of the external space-time is compactified on a circle, which shrinks smoothly to zero size at some finite value of the radial (holographic) direction. These are regular solutions, and the dual field theory yields linear confinement in three dimensions, as explicitly shown by the Wilson loops. We compute the spectrum of fluctuations, generalizing the results of Ref. \[\text{[60]}\], and discover new features, such as the emergence of an approximate dilaton.

### A. Sigma-model in \(D = 5\) dimensions

We denote with hatted symbols quantities characterizing the theory in \(D = 5\) dimensions. The action of the canonically normalized scalar \(\phi\) coupled to gravity is the following (in the notation of Ref. \[\text{[131]}\]):

\[
S_\phi = \int d^5x \sqrt{-g_5} \left( \frac{\hat{R}_5}{4} - \frac{1}{2} \hat{g}^{MN} \partial_M \phi \partial_N \phi - V_5 \right).
\]

Here \(\hat{g}_5\) is the determinant of the metric, \(\hat{g}^{MN}\) its inverse, and \(\hat{R}_5\) the Ricci scalar, while \(V_5\) is the potential.

The domain wall (DW) solutions manifestly preserve Poincaré invariance in four dimensions. They can be obtained by adopting the following ansatz for the metric,

\[
ds_{\text{DW}}^2 = e^{2A(\rho)} dx_{1,3}^2 + d\rho^2.
\]

By assumption, the only nontrivial functions determining the background are \(A(\rho)\) and \(\phi(\rho)\), with no dependence on other coordinates. The resulting second-order equations of motion are the following:

\[
0 = \partial_\rho \phi + 4 \partial_\rho A \partial_\rho \phi - \partial_\rho V_5,
\]

\[
0 = 4(\partial_\rho A)^2 + \partial_\rho^2 A + \frac{4}{3} V_5,
\]

\[
0 = 6(\partial_\rho A)^2 - \partial_\rho \phi \partial_\rho \phi + 2V_5.
\]

The conventions we are using \[\text{[16]}\] in writing the action in Eq. (2) are such that if the potential \(V_5\) of the model can be written in terms of a superpotential \(W\) satisfying

\[
V_5 = \frac{1}{2} (\partial_\rho W)^2 - \frac{4}{3} W^2,
\]

for the metric ansatz \(ds_{\text{DW}}^2\), then the solutions to the first-order equations
four-dimensional Poincaré invariance. Following Ref. [59], we therefore assume that the dimensional reduction of the gravity theory to four dimensions, we hence allow for the breaking of four-dimensional Poincaré invariance.

Regular background solutions in which the size of the circle shrinks smoothly to zero (at some finite value of the radial direction $\rho$) introduce a mass gap in the (lower-dimensional) dual field theory, and exhibit the physics of confinement—we discuss how in Secs. III C and III D.

We elect to describe the geometry by applying dimensional reduction of the gravity theory to four dimensions, with the introduction of a new dynamical scalar that encodes the size of the circle. In the remainder of this subsection we provide the technical details of the construction.

We reduce to $D = 4$ dimensions by adopting the following ansatz, as in Refs. [131,52]:

$$ds^2 = e^{-2\xi(r)}ds^2_3 + e^{\phi(r)}dr^2,$$

where the angle $0 \leq \eta < 2\pi$ parametrises a circle, the four-dimensional metric takes the domain wall form

$$ds^2_3 = e^{2\lambda(r)}dx^2 + dr^2,$$

and the new background scalar $\chi(r)$ and warp factor $A(r)$ depend only on the new radial coordinate $r$.

The action in $D = 4$ dimensions is

$$S_4 = \int d^4x \sqrt{-g_4} \left[ R_4 - g^{MN}_4 G_{ab} \partial_\mu \Phi^a \partial_\nu \Phi^b - \mathcal{V}_4 \right],$$

where the sigma-model metric for the scalar fields $\Phi^a = \{\phi, \chi\}$ is $G_{ab} = \text{diag}(1,3)$, and the potential is

$$\mathcal{V}_4 = e^{-2\xi} \mathcal{V}_5.$$ (14)

We explicitly verified that $S_5 = \int d\eta( S_4 + \partial \mathcal{S})$, where

$$\partial \mathcal{S} = \int d^4x \partial_M \left( \frac{1}{2} \sqrt{-g_4} g^{MN} \partial_N \chi \right).$$ (15)

After the change of variables $\partial_\rho = e^{-\tau} \partial_\rho$, the equations of motion for the background read as follows:

$$0 = \partial_\rho (3 \partial_\rho A - \partial_\rho \chi) + \partial_\rho^2 \phi + \sqrt{\frac{8}{3}} e^{-\tau} [e^{\sqrt{2}\phi} - 1],$$ (16)

$$0 = 3 \partial_\rho A \partial_\rho A - \partial_\rho^2 \chi - \frac{2}{3} e^{-\sqrt{2}\phi} [e^{\sqrt{2}\phi} + 1],$$ (17)

$$0 = \partial_\rho A \partial_\rho A - 3 \partial_\rho A^2 - \partial_\rho A + 2 e^{-\sqrt{2}\phi} [e^{\sqrt{2}\phi} + 1],$$ (18)

$$0 = 3 \partial_\rho A^2 - 3 \partial_\rho A \partial_\rho A - \partial_\rho^2 \phi - 2 e^{-\sqrt{2}\phi} [e^{\sqrt{2}\phi} + 1].$$ (19)

By combining Eqs. (17) and (18), we obtain

$$\partial_\rho [e^{3\lambda - \tau} (3 \partial_\rho A - \partial_\rho \chi)] = 0,$$ (20)

which defines a conserved quantity along the flow in $\rho$.

C. Lift to type IIB in $D = 10$ dimensions

We take the lift to type IIB supergravity in $D = 10$ dimensions from Ref. [134]. The dilaton/axion subsystem is trivial (see Sec. 3.2 of Ref. [134]), and there is no distinction between Einstein and string frames.

We parametrize the five-sphere $S^5$ in terms of five angles $0 \leq \theta \leq \pi/2$, $0 \leq \theta \leq \pi$, $0 \leq \phi, \hat{\phi} < 2\pi$, and $0 \leq \psi \leq 4\pi$. The $SU(2)$ left-invariant two-forms are

\begin{align*}
\mathbf{i} \mathbf{i} = &\ t \mathbf{d} \theta \\
\mathbf{i} \mathbf{i} = &\ t \mathbf{d} \phi \\
\mathbf{i} \mathbf{i} = &\ t \mathbf{d} \hat{\phi} \\
\mathbf{i} \mathbf{i} = &\ t \mathbf{d} \psi
\end{align*}
\[ \sigma_1 = \cos \psi d\tilde{\theta} + \sin \psi \sin \theta d\tilde{\varphi}, \]  
\[ \sigma_2 = \sin \psi d\tilde{\theta} - \cos \psi \sin \theta d\tilde{\varphi}, \]  
\[ \sigma_3 = d\psi + \cos \theta d\tilde{\varphi}, \]  

normalized according to \( d\sigma_i = \frac{1}{2} \sum_{jk} \epsilon_{ijk} \sigma_j \wedge \sigma_k \). We write the metric of the \( S^3 \) as \( d\Omega_3^2 = \frac{1}{2} \sum_{i=1}^3 \sigma_i^2 \), or

\[ d\Omega_3^2 = \frac{1}{4} [d\tilde{\theta}^2 + \sin^2 \tilde{\theta} d\tilde{\varphi}^2 + (d\psi + d\tilde{\varphi} \cos \theta)^2]. \]  

We then follow Ref. [134] (see also Ref. [159]), with the following identifications: we set the two scalars \( \{\alpha, \chi\} \) of Ref. [134] to \( \alpha = \phi/\sqrt{6} \) and \( \chi = 0 \) (not to be confused with \( \chi \) in this paper), we set the coupling \( g = 2 \), and the normalization in Eq. (3.14) of Ref. [134] to \( a^2 = 2 \). The metric in \( D = 10 \) dimensions is

\[ dx_{10}^2 = \Omega^2 dx_3^2 + d\Omega_3^2, \]  

where \( dx_3^2 \) has been introduced in Eq. (11), while

\[ d\Omega_3^2 = X^{1/2} \left( d\tilde{\theta}^2 + \frac{\tilde{\rho}^6}{X} \cos^2 \theta d\Omega_3^2 + \sin^2 \theta d\varphi^2 \right). \]  

The warp factor in the lift depends on \( \rho \) and \( \theta \), because

\[ \Omega^2 = \frac{X^{1/2}}{\tilde{\rho}}, \]  

where the functions determining the backgrounds are

\[ \tilde{\rho} = e^{\phi/\sqrt{6}}, \]  

\[ X = \cos^2 \theta + \tilde{\rho}^6 \sin^2 \theta. \]  

For \( \phi = 0 \) one has \( \tilde{\rho} = 1 = X \), and recovers the round \( S^5 \). The isometries associated with \( d\Omega_3^2 \) and \( d\varphi^2 \) match the \( SO(4) \) and \( SO(2) \) symmetries of the field theory.

By making use of the equations of motions for the scalars \( \phi \) and \( \chi \) and for the function \( A \), we find that \( R_{10} = 0 \) identically. Yet, other invariants, such as the square of the Ricci and Riemann tensors, are nontrivial.

**D. Rectangular Wilson loops**

The expectation value of rectangular Wilson loops of sizes \( L \) and \( T \) in space and time, respectively, is computed using the standard holographic prescription [20,21] (see also Refs. [22–24]). Open strings, with extrema bound to the contour of the loop on the boundary of the space at \( \rho = +\infty \), explore the geometry down to the turning point \( \tilde{\rho}_o \) in the holographic direction, and the problem reduces to a minimal surface one. The warp factor \( \Omega^2 \) depends on \( \theta \), but we restrict attention to configurations with \( \theta \) held fixed, and focus on the limiting cases \( \theta = 0 \) and \( \theta = \pi/2 \). Taking \( T \to +\infty \), we obtain the effective potential between static quarks as a function of the separation \( L \) between end-points of the string.

The calculation of the Wilson loop can proceed along the lines of the prescription in Refs. [22–26]. Starting from the elements of the metric in \( D = 10 \) dimensions, \( ds^2 = g_{\mu\nu} dx^\mu dx^\nu + g_{\varphi\varphi} d\varphi^2 + \cdots \), we introduce the functions \( F^2(\rho, \theta) = -g_{\varphi\varphi} \) and \( G^2(\rho, \theta) = -g_{\rho\rho} \), and the convenient quantity

\[ V_{\text{eff}}^2(\rho, \tilde{\rho}_o) \equiv \frac{F^2(\rho, \tilde{\rho}_o)G^2(\rho)}{(F^2(\rho) - F^2(\tilde{\rho}_o))}, \]  

where the dependence on (constant) \( \theta \) is implicit. The separation between the end points of the string is

\[ L(\tilde{\rho}_o) = 2 \int_{\tilde{\rho}_o}^\infty d\rho \frac{1}{V_{\text{eff}}(\rho, \tilde{\rho}_o)}, \]  

and the profile of the string in the \( (\rho, x) \)-plane is

\[ x(\rho) = \begin{cases} f_{\rho} \frac{d\varphi}{V_{\text{eff}}(\rho, \tilde{\rho}_o)}, & x < L(\tilde{\rho}_o)/2, \\ L(\tilde{\rho}_o) - f_{\rho} \frac{d\varphi}{V_{\text{eff}}(\rho, \tilde{\rho}_o)}, & x > L(\tilde{\rho}_o)/2. \end{cases} \]  

The energy of the resulting configuration is

\[ E(\tilde{\rho}_o) = 2k \int_{\tilde{\rho}_o}^\infty d\rho \sqrt{\frac{F^2(\rho)G^2(\rho)}{F^2(\rho) - F^2(\tilde{\rho}_o)}}. \]  

As \( g_{\varphi\varphi} = -g_{\rho\rho} = \Omega^2 e^{2\bar{a} - 2\bar{c}} \) and \( g_{\rho\rho} = \Omega^2 \), we find the \( \theta \)-dependent functions \( F^2(\rho, \theta) = \bar{X} \bar{\rho}^{-2} e^{2\bar{a} - 2\bar{c}} \) and \( G^2(\rho, \theta) = \bar{X} \bar{\rho}^{-2} e^{2\bar{a} - 2\bar{c}} \), also written explicitly as

\[ F^2(\rho, \theta) = (\cos^2 \theta + e^{\sqrt{6} \phi} \sin^2 \theta) e^{2\bar{a} - 2\bar{c}}, \]  

\[ G^2(\rho, \theta) = (\cos^2 \theta + e^{\sqrt{6} \phi} \sin^2 \theta) e^{2\bar{a} - 2\bar{c}}. \]  

Eq. (33) is UV divergent, requiring the introduction of \( \rho_A \) as a UV cutoff, and to define the regulated \( E_A(\tilde{\rho}_o) \) by restricting the range of integration. We define the following:

\[ \Delta E_{A,\theta} \equiv 2k \int_{\rho_o}^{\rho_A} d\rho G(\rho, \theta), \]  

where the integral extends all the way to the end of space \( \rho_o \), choose the case \( \theta = 0 \) as a counterterm, and finally define the renormalized energy as

\[ \Delta E \cdots \]
\[ E_W(\hat{\rho}_o) \equiv \lim_{\rho_o \to +\infty} (E_N(\hat{\rho}_o) - \Delta E_{\Lambda,0}). \]  

In confining theories, at large separations \( L(\hat{\rho}_o) \) the energy grows linearly and the string tension is given by

\[ \sigma_{\text{eff}} \equiv \lim_{\hat{\rho}_o \to +\infty} \frac{dE_W(\hat{\rho}_o)}{dL(\hat{\rho}_o)} = F(\rho_o). \]  

A limiting configuration consists of two straight rods at distance \( L \), both with fixed \( \theta \), extending from the boundary to the end of space, connected by a straight portion of string at \( \hat{\rho}_o = \rho_o \). Its energy is \( E_\theta = \Delta E_{\Lambda,\theta} - \Delta E_{\Lambda,0} + F(\rho_o, \theta)L \). If \( F(\rho_o, \theta) \) vanishes, this configuration is indistinguishable from two disconnected ones, yielding screening in the dual theory—barring the caveats discussed in Ref. [160]. We set the normalization \( \kappa = 1 \) from here on. There may be cases in which this procedure shows the emergence of a phase transition for the theory living on the probe [23] (see also the discussions in Refs. [26,161]).

### III. BACKGROUND SOLUTIONS

We classify in this section the background solutions we are interested in. We present their UV and IR expansions, and discuss curvature invariants and Wilson loops.

#### A. UV expansions

All the solutions of interest have the same asymptotic UV expansion, and they all correspond to deformations of the same dual theory. We expand them for \( \hat{z} = e^{-\rho} \ll 1 \)

\[ \phi(z) = z^2 \phi_2 + z^2 \phi_{2l} \log(z) \]

\[ + \frac{\sqrt{6}}{12} z^4 (2 \phi_2^2 - 4 \phi_2 \phi_{2l} + 3 \phi_{2l}^2) \]

\[ + \frac{\sqrt{6}}{3} z^4 \log(z) (\phi_2 \phi_{2l} - \phi_{2l}^2) \]

\[ + \frac{z^4 \phi_{2l}^2 \log^2(z)}{\sqrt{6}} + O(z^6), \]  

\[ \chi(z) = \chi_U - \frac{\log(z)}{2} + \chi_4 z^4 - \frac{1}{6} z^4 \phi_{2l}^2 \log(z) \]

\[ - \frac{1}{12} z^4 \phi_{2l}^2 \log^2(z) + O(z^6). \]  

\[ A(z) = A_U - \frac{3 \log(z)}{2} - \frac{1}{2} z^4 \phi_{2l} \log(z) \]

\[ + z^4 \left( \frac{\chi_4}{3} - \frac{1}{36} (8 \phi_2^2 + \phi_{2l}^2) \right) \]

\[ - \frac{1}{4} z^4 \phi_{2l}^2 \log^2(z) + O(z^6). \]

The integration constant \( A_U \) can be reabsorbed and set to zero, while \( \chi_U \) can be removed by a shift of radial coordinate \( \rho \). \( \phi_2 \) is associated with the VEV of the aforementioned dimension-two operator of the dual field theory, and \( \phi_{2l} \) with its (supersymmetry-breaking) coupling. The parameter \( \chi_4 \) is associated with the VEV of a dimension-four operator which triggers confinement.

Domain wall solutions in \( D = 5 \) dimensions are recovered (locally) for \( A = A - \chi = 2 \chi_* \), yielding two constraints on the five parameters of a generic solution,

\[ A_U = 3 \chi_U, \quad \chi_4 = -\frac{1}{96} (8 \phi_2^2 + \phi_{2l}^2). \]  

We illustrate the behavior of the singular DW solutions with the comprehensive catalogue in Fig. 2. We devote to them Secs. III B and III C (and Appendix A), before discussing in Sec. III D the scion of regular solutions corresponding to confining theories in three dimensions.

#### B. The negative DW family

The DW solutions for which \( \phi \) diverges to \(-\infty\) at the end of space generalise the \( n = 2 \) supersymmetric case—see the dashed (red) lines in Fig. 2. The background functions, evaluated near the end of space \( \rho_o \), are
\[ \phi_-(\rho) = \phi_o + \frac{1}{2} \sqrt{3} \log(\rho - \rho_o) \]
\[ + \frac{4}{9} \sqrt{\frac{2}{3}} (\rho - \rho_o)^2 e^{-4\sqrt{3} \phi_o} + \cdots \] (43)

\[ A_-(\rho) = A_I + \frac{\log(\rho - \rho_o)}{4} \]
\[ + \frac{2}{3} (\rho - \rho_o) e^{-2\sqrt{3} \phi_o} + \cdots \] (44)

Ignoring the inconsequential constants \( A_I \) and \( \rho_o \), this one-parameter family of solutions is labeled by the free parameter \( \phi_o \). The curvature invariants of the gravity formulation in \( D = 5 \) dimensions diverge; lifting to \( D = 10 \) dimensions, the singular behavior first appears in

\[ \mathcal{R}_{10, \hat{S} \hat{N}} \mathcal{R}_{10} = \frac{10 e^{-\sqrt{6} \phi_o}}{\cos^2(\theta)(\rho - \rho_o)^{3/2}} + \cdots \] (45)

A special limiting case (corresponding to \( \phi_o \rightarrow -\infty \)) of the (singular) negative DW solutions is represented by the thick (gray) line in Fig. 2, and is given by the IR expansions in Eqs. (A7) and (A8). It satisfies the first-order equations, as it coincides with the supersymmetric solutions \( (\phi_2, A_2) \) described by Eqs. (A3) and (A4)—the solution corresponding to the \( (n = 2) \) case of D3 branes distributed on a disk \( (B^2) \).

The study of the Wilson loops is exemplified in Fig. 3. The top-left panel depicts the case of backgrounds \( (\phi_-, A_-) \) with \( \phi_o = -1 \). The string is tensionless at the end of space, as \( \lim_{\rho \rightarrow \rho_o} F^2(\rho) = 0 \) for both choices \( \theta = 0, \pi/2 \). The separation \( L \) converges to zero for strings with end points at \( \rho = +\infty \), when the turning point of the string configuration reaches the end of space, yielding the description of a phase transition such that the Wilson loop mimics screening at large \( L \).

### C. The positive DW family

In the stream plot in Fig. 2, the long-dashed (blue) lines are examples of DW solutions in which the scalar \( \phi \) diverges to \( \phi \rightarrow +\infty \) at the end of space. Their IR expansions are
\[
\phi_+(\rho) = \phi_o - \frac{1}{2} \sqrt{\frac{3}{2}} \log(\rho - \rho_o) \\
+ \frac{8}{15} \sqrt{\frac{2}{3}} e^{\sqrt{\phi_o}} (\rho - \rho_o)^{3/2} + \cdots \tag{46}
\]
\[
\mathcal{A}_+(\rho) = \mathcal{A}_t + \frac{\log(\rho - \rho_o)}{4} \\
+ \frac{32}{45} (\rho - \rho_o)^{3/2} e^{\sqrt{\phi_o}} + \cdots \tag{47}
\]

These solutions generalize the supersymmetric one denoted \((\phi_+, \mathcal{A}_+\)) in Eqs. (A5) and (A6)—the solutions corresponding to the \((n = 4)\) case of D3 branes distributed on \(\mathbf{B}^4\)—to a one-parameter family, labeled by \(\phi_o\). The supersymmetric case is recovered with the choice \(\phi_o = -\frac{1}{2} \sqrt{\frac{3}{2}} \log(\frac{4}{3})\), and is highlighted by a darker long-dashed line in Fig. 2.

The five-dimensional curvature invariants diverge. In \(D = 10\) dimensions the divergence appears in
\[
\mathcal{R}_{10, \hat{M} \hat{N}} \mathcal{R}^{\hat{M} \hat{N}} = \frac{405 e^{-8 \sqrt{\phi_o}/\sin^4(2\theta)}}{2048 \sin^{10}(\theta)} + \cdots \tag{48}
\]

The limit \(\theta \to 0\) is singular at the end of space, even in the case of the supersymmetric solution—see also Eq. (A12) and the discussion that follows it.

The calculation of the Wilson loops is exemplified in the top-right and bottom-left panels in Fig. 3, for \(\phi_o = -1\) and \(\phi_o = +1\), respectively. For \(\theta = 0\), once more \(\lim_{\rho \to \rho_o} F^2(\rho) = 0\). The separation \(L\) vanishes when the turning point of the string configuration reaches the end of space, as we found for \((\phi_-, \mathcal{A}_-\)) before. But in the case \(\theta = \pi/2\), we find that \(\lim_{\rho \to \rho_o} F^2(\rho) = \sigma^2 > 0\) is finite. The separation \(L\) diverges, and one recovers the linear potential \(E_W \approx \sigma L\).

When \(\phi_o < -\frac{1}{2} \sqrt{\frac{3}{2}} \log(\frac{4}{3})\), the assumption of keeping \(\theta\) fixed fails, as at small \(L\) the configurations with \(\theta = \pi/2\) have lower energy than those with \(\theta = 0\), while at large \(L\) the converse is true.

1. Special positive DW solutions

A limiting case of the positive DW solutions is depicted by the short-dashed (purple) line in Fig. 2. The IR expansions are
\[
\phi_\infty(\rho) = \sqrt{\frac{3}{2}} \log\left(\frac{45}{2}\right) - \sqrt{6} \log(\rho - \rho_o) \\
+ \frac{2 \sqrt{3}}{59535 \sqrt{3}} (\rho - \rho_o)^6 + \cdots \tag{49}
\]
\[
\mathcal{A}_\infty(\rho) = \mathcal{A}_t + 4 \log(\rho - \rho_o) \\
+ \frac{16}{893025} (\rho - \rho_o)^6 + \cdots \tag{50}
\]

The only parameters are the inconsequential \(\mathcal{A}_t\) and \(\rho_o\). The five-dimensional curvature invariants diverge, but the lift to \(D = 10\) dimensions yields
\[
\mathcal{R}_{10} = 0 = \lim_{\rho \to \rho_o} \mathcal{R}_{10, \hat{M} \hat{N}} \mathcal{R}^{\hat{M} \hat{N}}. \tag{51}
\]

Yet, these solutions are singular as well, as illustrated by the simultaneous limits \(\rho \to \rho_o\) and \(\theta \to 0\) of the square of the Riemann tensor,
\[
\lim_{\rho \to \rho_o} \left(\mathcal{R}_{10, \hat{M} \hat{N}} \mathcal{R}^{\hat{M} \hat{N}}\right)^2 = \frac{9(15 + 10 \sin^2(\theta) + 7 \sin^4(\theta))}{5 \sin^6(\theta)}. \tag{52}
\]

These solutions are the limiting case \(\phi_o \to +\infty\) of the \((\phi_+, \mathcal{A}_+)\) general class, and the bottom-right panel in Fig. 3 shows a peculiarly interesting behavior for the quark-antiquark potential. The separation \(L\) is unbounded, the potential vanishes for \(L \to +\infty\), and so does the string tension. We find the potential \(E_W \approx -e^{1/6}/L\) at short \(L\), and \(E_W \approx -e^6/L^2\) at large \(L\) (for \(\mathcal{A}_t = 0\)).

While the results of the study of the Wilson loops for the DW solutions are very suggestive, with the emergence of screening, confining, several types of Coulombic potentials and phase transitions, they must be all taken with caution; all the background solutions discussed so far (and in Appendix A) are singular. Hence, such solutions cannot be considered as complete gravity duals of field theories, but they provide only approximate descriptions that may miss important long-distance details.

D. Confining solutions

The solutions of this class are completely regular, and dual to confining, three-dimensional field theories. Here we present their IR expansions, discuss the gravitational invariants, and compute the Wilson loops. The expansion in proximity of the end of space \(\rho_o\), is
\[
\phi_c(\rho) = \phi_t - \frac{(\rho - \rho_o)^2 e^{-2 \sqrt{\phi_t}} (e^{\sqrt{\phi_t}} - 1)}{\sqrt{6}} \\
+ \mathcal{O}((\rho - \rho_o)^4), \tag{53}
\]
\[
\chi_c(\rho) = \chi_t + \frac{\log(\rho - \rho_o)}{2} \\
- \frac{1}{18} (\rho - \rho_o)^2 e^{-2 \sqrt{\phi_t}} (2 e^{\sqrt{\phi_t}} + 1) \\
+ \mathcal{O}((\rho - \rho_o)^4), \tag{54}
\]
\[ A_C(\rho) = A_I + \frac{\log(\rho - \rho_o)}{2} + \frac{5}{18}(\rho - \rho_o)^3 e^{-2\sqrt{2} \phi_I} (2e^{\sqrt{2} \phi_I} + 1) + O((\rho - \rho_o)^4). \] (55)

The gravity invariants in five dimensions are finite, and when restricted to the \((\rho, \eta)\) plane, the metric reduces to
\[ ds^2 = d\rho^2 + e^{4\chi}(\rho - \rho_o)^2 d\eta^2. \] (56)

We fix \(\chi_I = 0\) in order to avoid a conical singularity. The integration constant \(A_I\) is trivial and can be reabsorbed by a rescaling of the three Minkowski directions. The constant \(\phi_I\) characterizes this one-parameter family of solutions. The curvature invariants of the lift to \(D = 10\) dimensions are regular, for all choices of \(0 \leq \theta \leq \pi/2\).

In the study of the rectangular Wilson loop (in three dimensions) we fix \(\theta\) and allow the two sides of the rectangle to align with time and one noncompact spacelike direction. The static potential \(E_W(L)\) is illustrated by Fig. 4, for two representative choices with \(\phi_o \pm 1\). The short-distance Coulombic behavior gives way to the linear potential typical of confinement, and \(L\) is unbounded. For this reason, with some abuse of language, we call these regular solutions confining. We can compute the string tension, and we find
\[ \sigma_0 \equiv \lim_{\rho_o \to \rho_o^+} F(\hat{\rho}_o, 0) = e^{2A_I - 2\chi_I - \sqrt{2} \phi_I}, \] (57)
\[ \sigma_{\pi/2} \equiv \lim_{\rho_o \to \rho_o^- \pi/2} F(\hat{\rho}_o, \pi/2) = e^{2A_I - 2\chi_I + \sqrt{2} \phi_I}. \] (58)

The configuration with \(\theta = 0\) has lower energy in the case where \(\phi_I > 0\), and vice versa.

**IV. MASS SPECTRA AND PROBE APPROXIMATION**

The spectrum of small fluctuations of a sigma model coupled to gravity of the form of Eqs. (2) and (13) in generic \(D\) dimensions can be interpreted in terms of the spectrum of bound states of the strongly-coupled dual field theory, by applying the dictionary of gauge-gravity dualities. We adopt the gauge-invariant formalism described in detail in Refs. [15–19]. Due to the divergences in the deep IR and far UV, we introduce two unphysical boundaries \(\rho_1 < \rho < \rho_2\) in the radial direction—the physical results are recovered in the limits \(\rho_2 \to +\infty\) and \(\rho_1 \to \rho_o\). The calculation involves fluctuating solutions for which the metric has the DW form in \(D\) dimensions. The confining solutions assume the DW form in the dimensionally reduced \((D = 4)\) formulation of the theory. For the confining solutions, it is also understood that in the following equations (59)–(62) appearing in this section of the paper, \(\mathcal{A}\) is to be replaced by \(\Lambda\).

The tensorial fluctuations \(e^a\) are gauge invariant, obey the equations of motion
\[ [\partial^2 + (D - 1)\partial_\rho \mathcal{A}_\rho + e^{-2\mathcal{A}_\rho} M^2] e^a = 0, \] (59)
where \(M\) is the mass in \(D - 1\) dimensions, and are subject to Neumann boundary conditions \(\partial_\rho e^a \big|_{\rho_1} = 0\). The scalar gauge invariant fluctuations \(a^a \equiv q^a - \frac{\partial_\rho \phi^a}{\pi(D-2)\mathcal{A}} h\) are a combination of fluctuations \(q^a\) of the scalar fields and \(h\) of the trace of the metric. They obey the following equations of motion and boundary conditions
\[ 0 = [D^2 + (D - 1)\partial_\rho \mathcal{A} \partial_\rho + e^{-2\mathcal{A}_\rho} M^2] a^a - V^a |_{\rho_1} + \frac{4(\partial_\rho \phi^a V^b + V^a \partial_\rho \phi^b G_{bc})}{(D - 2)\partial_\rho \mathcal{A}} \] (60)
\[ + \frac{16V \partial_\rho \phi^a \partial_\rho \phi^b G_{bc}}{(D - 2)^2(\partial_\rho \mathcal{A})^2} a^c, \]
\[ 0 = \frac{2e^{2\mathcal{A}_\rho} \partial_\rho \phi^a}{(D - 2)M^2 \partial_\rho \mathcal{A}} \left[ \partial_\rho \phi^b D_\rho \frac{4V \partial_\rho \phi^b}{(D - 2) \partial_\rho \mathcal{A}} - V^b \right] a_b + a^a |_{\rho_1}. \] (61)

**FIG. 4.** Energy \(E_W\) as a function of the separation \(L\), for two representative confining solutions, chosen to have \(A_I = 0 = \chi_I\), and \(\phi_I = -1\) (top) or \(\phi_I = +1\) (bottom). Continuous (blue) lines correspond to configurations with \(\theta = 0\), short-dashed (red) lines to configurations with \(\theta = \pi/2\).
The notation follows the conventions of Ref. [19]. The sigma-model metric being trivial, the covariant derivative simplifies to $V_{\mu} = \partial_{\mu} (G^{ab} \partial_{\nu} V)$, and the background-covariant derivative to $\mathcal{D}_\rho a^\mu = \partial_\rho a^\mu$.

The probe approximation is defined according to the prescription tested in Ref. [131], and we use it as a diagnostic tool to identify particles coupled to the trace of the energy momentum tensor, because of their mixing with $h$. The probe approximation ignores the fluctuation $h$, in the definition of $a^\mu$, yielding variables $p^\mu$ that satisfy

$$0 = \left[ \mathcal{D}_\rho^2 + (D - 1) \partial_\rho \mathcal{A} \partial_\rho - e^{-2A} q^2 \right] p^\rho - V a^\rho p^c,$$  \hspace{1cm} (62)

subject to Dirichlet boundary conditions $p^\rho |_{\rho_0} = 0$.

The fluctuation $h$ is interpreted as the bulk field coupled to the dilatation operator in the dual field theory. If the approximation of ignoring $h$ captures correctly the spectrum, then the associated scalar particle is not a dilaton. Conversely, the probe approximation either completely misses, or fails to capture the correct mass of, an approximate dilaton. We tested these ideas on a large selection of examples in Ref. [131].

In order to improve the convergence of the numerical computation of the spectrum, we make use of the UV expansions for the fluctuations given in Appendix B, setting up the boundary conditions such that only the subleading modes are retained. This is the customary prescription, as well as the one selected by the boundary conditions in Eq. (61), in the limit in which we remove the UV regulator (boundary) at $\rho_2$.

We start the analysis from the DW solutions. The result of the numerical study of the fluctuations for the $(\phi_-.A_-)$ solutions is displayed in Fig. 5, as a function of the parameter $\phi_o$ characterizing this one-parameter family. We find it convenient to normalize the masses $M$ of the spin-zero (blue disks) and spin-two states (red circles) so that the lightest tensor mode has unit mass.

For any finite value of $\phi_o$, the spectrum is characterized by an unremarkable discrete sequence of states, and by the existence of a tachyon, which signals a fatal instability in the background solutions. Only in the strict limit $\phi_o \rightarrow -\infty$ does the tachyon become exactly massless. In the same limit, the spectrum degenerates to a gapped continuum, in all the channels, for $M^2 > 1$ (in units of the lightest tensor mode). This result reproduces the results quoted from the literature in Appendix A, for the $n = 2$ case, confirming that the gauge-invariant formalism we adopt, the choices of boundary conditions we impose, and the numerical strategy we deploy combine to correctly identify all the poles of the relevant two-point correlation functions.

By comparing the gauge-invariant spin-zero fluctuations to the probe approximation (the black diamonds in Fig. 5), we clearly see that the probe approximation fails most completely to capture the lightest (tachyonic) masses, for all values of $\phi_o$, so that we can establish that the dilaton component is always important in such spin-zero objects. Mixing effects become prevalent for negative $\phi_o$. For large and positive values of $\phi_o$, the probe approximation captures well the excited scalar states, and hence yields a clear, unambiguous identification of the dilaton with the tachyon.

One difference appears immediately evident; there is a region of parameter space, bounded by the supersymmetric $n = 4$ solution, for which $\phi_o > -\frac{1}{2} \sqrt{2 \log(2)}$, and in which all the scalar states have positive-definite mass squared. (We also saw in Sec. III C, and particularly in Sec. III C 1, that solutions of this type have a milder singularity.)

Once more the spectrum of the supersymmetric background is in agreement with the literature, which further confirms that our numerical strategy is reliable. The spectrum for $\phi_o < -\frac{1}{2} \sqrt{2 \log(2)}$ always contains a tachyon, followed by a light scalar state and a densely packed sequence of heavy excitations. In the limit $\phi_o \rightarrow -\infty$, the spectrum agrees with the case of the supersymmetric solution $(\phi_2, A_2)$, except for the addition of a tachyon. Indeed, this superficially surprising feature can be explained by close examination of the stream plot in...
Fig. 6. Mass spectrum of the fluctuations of the positive DW solutions. The (red) circles are the spin-two states, the (blue) disks are the spin-zero states, and the (black) diamonds represent the probe approximation calculation of the spin-zero masses. The masses $M$ are normalized to the lightest spin-two state, and plotted as a function of $\phi_o$, defined in Eqs. (46) and (47). The special case of the supersymmetric solutions in Eqs. (A5) and (A6) is the choice of $\phi_o$ that yields a massless scalar state, and is marked by a vertical dashed line. The numerical calculations are performed with finite cutoffs $\rho_1 = 10^{-6}$ and $\rho_2 = 8$. We checked explicitly that these choices are close enough to the physical limits $\rho_1 \to \rho_o = 0$ and $\rho_2 \to +\infty$ that the numerical results do not display any important residual spurious dependence on the cutoffs.

Fig. 7. Mass spectrum of the fluctuations of the confining solutions. The spectrum can be interpreted in terms of the masses of bound states in a confining theory in three dimensions. The (red) circles are the spin-two states, the (blue) disks are the spin-zero states, and the (black) diamonds represent the probe approximation calculation of the spin-zero masses. The masses $M$ are normalized to the lightest spin-two state, and plotted as a function of $\phi_I$, defined in Eq. (53). The vertical dashed line denotes the value of the parameter $\phi_I = \phi^{II}_0 \approx 0.067$ at which a phase transition takes place. The numerical calculations are performed with finite cutoffs $\rho_1 = 10^{-6}$ and $\rho_2 = 8$. We checked explicitly that these choices are close enough to the physical limits $\rho_1 \to \rho_o = 0$ and $\rho_2 \to +\infty$ that the numerical results do not display any important residual spurious dependence on the cutoffs.

In summary, in the case of the confining solutions, and for $\phi_I > \phi^{II}_0 \approx 0.52$, the solutions are regular (the curvature invariants computed in $D = 5$ and $D = 10$ dimensions

$$M_0 = 0.69, 1.62, 2.37, 3.10, 3.81, 4.53, \ldots \quad \text{(64)}$$

We extend the numerical study to the whole one-parameter scion of solutions characterized by $\phi_o$, and retain both fluctuations of $\phi$ and $\chi$. The resulting spectrum is displayed in Fig. 7. The masses of scalars (blue disks) and tensors (red circles) are plotted as a function of $\phi_I$. We also display the result of applying the probe approximation to the treatment of the scalars (black diamonds). For $\phi_I = 0$, the tensor masses, as well as the masses of half the scalars (the second, fourth, sixth, eighth, ...) are in excellent agreement with Ref. [60], confirming for the third time the robustness of our procedure. Yet, the truncation adopted in Ref. [60] misses the lightest of the scalar states, which can be decoupled only for $\phi = 0$—in this case, the probe approximation is accurate for the first, third, fifth, ..., scalar states, but only within a narrow range around $\phi = 0$.

The main feature that emerges is that the spectrum is positive definite only for $\phi_I > \phi^{II}_0 \approx 0.52$. For large and negative values of $\phi_I$, we find the emergence of a tachyon, signaling the appearance of an instability. The probe approximation fails to capture the features of the spectrum, even at the qualitative level, yielding an unphysical proliferation of tachyons.

In summary, in the case of the confining solutions, and for $\phi_I > \phi^{II}_0 \approx 0.52$, the solutions are regular (the curvature invariants computed in $D = 5$ and $D = 10$ dimensions
are all finite) and smooth (there is no conical singularity at the end of space), the spectrum is positive definite, and the calculation of the Wilson loop via the dual gravity prescription leads to the linear potential expected in a confining field theory (in three dimensions). All of these properties are preserved all the way along the scion of confining solutions until the critical value \( \phi_1 \), in proximity to the BF bound is the starting point of the realization of the ideas exposed in Ref. [3], where the unitarity bound. In this sense, this model is a more direct deforming field theory operator exactly saturating the BF bound.

V. FREE ENERGY AND STABILITY ANALYSIS

Because we regulate the theory by introducing two boundaries \( \rho_1 \) and \( \rho_2 \) in the radial direction of the geometry, the complete action in \( D = 5 \) dimensions must include also boundary-localized terms,

\[
S = S_\text{a} + \sum_{i=1,2} (-) i \int d^3 x \sqrt{-\tilde{g}} \left( K/2 + \lambda_i \right)_{|\rho_i}. \quad (65)
\]

The Gibbons-Hawking-York (GHY) term is proportional to the extrinsic curvature \( K \) and \( \lambda_i \) are boundary potentials. We choose \( \lambda_1 = -\partial_\rho A \big|_{\rho = \rho_1} \), and, as in Ref. [12]—see also Eq. (3.66) of Ref. [153],

\[
\lambda_2 = -\frac{3}{2} - \phi^2 \left( 1 + \frac{1}{\log(k^2 z_2^2)} \right), \quad (66)
\]

where \( z_2 = e^{-\rho_2} \), and the freedom in the choice of \( k \) reflects the scheme-dependence of the result.

The explicit appearance of the term containing the unphysical constant \( k \) in this result is a peculiarity of this model, distinguishing it from those in Refs. [1,2]. It is due to the mass of the scalar field corresponding to the deforming field theory operator exactly saturating the BF unitarity bound. In this sense, this model is a more direct realization of the ideas exposed in Ref. [3], where the proximity to the BF bound is the starting point of the analysis. As we shall see shortly, though, our results here are qualitatively similar to those in Refs. [1,2].

The need for counterterms that are quadratic in \( \phi \), and their scheme dependence, imply that the concavity theorems do not hold for the free energy of this system. The free energy \( F \) and its density \( F \) are defined as

\[
F = -\lim_{\rho \to \rho_2} \lim_{\rho_2 \to -1} S^{\text{on-shell}} = \int d^3 x \sqrt{-\tilde{g}} F, \quad (67)
\]

and by using the equations of motion, supplemented by the observation that Eq. (20) defines a conserved quantity along the radial direction \( \rho \), we find

\[
F = -\lim_{\rho \to -1} \lim_{\rho_2 \to -1} e^{3\lambda_2} (\partial_\rho A + \lambda_2)|_{\rho_2}. \quad (68)
\]

We can now use the UV expansions, take the \( e^{-\rho_2} \to 0 \) limit, and arrive at

\[
F = \frac{1}{18} e^{3\lambda_2} \left( 2 \phi_2^2 + 9 \phi_2 \phi_2 - 2 \phi_2^2 \right)
+ 24 \chi_4 - 9 \phi_2^2 \log(k)). \quad (69)
\]

For the DW solutions, further simplifications yield

\[
F^{(DW)} = \frac{1}{8} e^{3\lambda_2} (4 \phi_2 - \phi_2 - 4 \phi_2 \log(k)) \phi_2. \quad (70)
\]

Along the lines of Ref. [1], we find it convenient to define a scale \( \Lambda \) as follows [162]:

![Diagram](image_url)

**FIG. 8.** The free energy density \( F \Lambda^{-4} \), defined in Eq. (70), expressed in units of the scale-setting parameter \( \Lambda \) defined in Eq. (71), plotted as a function of the deformation parameter \( \phi_2/\Lambda^{-2} \), for the various classes of solutions considered in the paper. For the confining solutions, the tachyonic backgrounds are denoted by continuous (black) lines, while backgrounds with a positive-definite mass spectrum are represented by the (black) short-dashed line. The long-dashed (blue) lines are the positive DW solutions, the dashed (red) lines are the negative DW solutions, while the gray disk represents the supersymmetric solutions. The bottom panel is a detail of the top one.
While this is not a unique choice, its simplicity and universality gives it a practical value for our applications. In the calculation of the free energy density, we set \( k = \Lambda \), as this quantity scales with dilatations in the same way as \( \varepsilon^{-1} \).

We display in Fig. 8 the result of the calculation of \( \mathcal{F}\Lambda^{-4} \) as a function of the source \( \phi_I/\Lambda^{-2} \), for the three classes of negative DW, positive DW and confining solutions. For negative values of \( \phi_I/\Lambda^{-2} \), as we saw the regular confining solutions have a positive definite spectrum (as \( \phi_I > \phi_I^* \)), and furthermore their free energy is the lowest among the solutions we considered. When \( \phi_I/\Lambda^{-2} \) is positive, but small, we still find regular confining solutions, but the lightest scalar state has lower mass, which vanishes when \( \phi_I = \phi_I^* \approx -0.52 \), after which it turns tachyonic. There is hence a regime of parameter space in which the lightest scalar has suppressed mass. But these solutions are metastable; the positive DW solutions (despite being singular) have lower free energy when \( \phi_I/\Lambda^{-2} > \phi_I^*/\Lambda^{-2} \approx 0.13 \), the critical value identified by the crossing in Fig. 8 (corresponding to \( \phi_I^* \approx -0.067 \)). Once more, as in the models in Refs. [1,2], we find that the lightest scalar can be identified with a parametrically light dilaton along the metastable solutions. In the stable solutions the lightest scalar is still an approximate dilaton, but not parametrically light.

VI. CONCLUSION AND OUTLOOK

We studied new classes of background solutions of maximal supergravity in \( D = 5 \) dimensions, truncated to retain only one scalar field. This is the theory related to the dual of the Coulomb branch of \( \mathcal{N} = 4 \) SYM. We focused on solutions that are regular, have a positive definite spectrum, and can be interpreted as the gravity dual of confining field theories in three dimensions. We found evidence that the lightest scalar state is an approximate dilaton, and can be made parametrically light, in a region of parameter space in which these new regular solutions are metastable.

The study confirms, in a lower-dimensional simple setting, for a well known example of gauge-gravity duality related to the study of \( \mathcal{N} = 4 \) SYM, the qualitative features that emerged in the models in Refs. [1,2]. We notice the emergence of a first-order phase transition separating the metastable from the stable portions of the parameter space of the new confining solutions. As in Refs. [4–6], the approximate dilaton is not parametrically light in the stable solutions, confirming this generic feature also in confining theories in three dimensions.

Further exploration of the catalog of supergravity theories will possibly help to understand whether the aforementioned results are universal or model dependent. Of particular interest would be to ascertain whether it is possible—and under what conditions—to find systems for which the phase transition is weak enough to render the dilaton parametrically light already in the stable region of parameter space, in proximity of the phase transition itself. It would also be interesting to see whether systems exist for which the phase transition is of second order.

P. has also received funding from the European Research Council (ERC) under the European Union Horizon 2020 research and innovation programme under Grant Agreement No. 813942. J. R. is supported by STFC, through the studentship No. ST/R505158/1.

APPENDIX A: THE TWO SUPERSYMMETRIC SOLUTIONS

The first-order Eqs. (8) can be solved exactly by changing variable according to \( \partial_\rho = e^{\frac{2}{\sqrt{6}}\tau} \partial_\tau \). The first-order equations are then

\[
\partial_\tau \phi(\tau) = -\frac{4}{\sqrt{6}} \sinh\left(\sqrt{\frac{3}{2}} \phi(\tau)\right),
\]

\[
\partial_\tau A(\tau) = \cosh\left(\sqrt{\frac{3}{2}} \phi(\tau)\right) - \frac{1}{3} \sinh\left(\sqrt{\frac{3}{2}} \phi(\tau)\right).
\]

There are two exact solutions [23,147,151]. The case of \( n = 2 \) is given by

\[
\phi_2(\tau) = -\frac{4}{\sqrt{6}} \operatorname{arctanh}(e^{-2(\tau - \tau_o)}),
\]

\[
A_2(\tau) = A_o + \tau - \tau_o - \frac{1}{3} \operatorname{arctanh}(e^{-2(\tau - \tau_o)} + \frac{1}{2} \log(1 - e^{-4(\tau - \tau_o)}),
\]

and the \( n = 4 \) case by

\[
\phi_4(\tau) = \frac{4}{\sqrt{6}} \operatorname{arctanh}(e^{-2(\tau - \tau_o)}),
\]

\[
A_4(\tau) = A_o + \tau - \tau_o + \frac{1}{3} \operatorname{arctanh}(e^{-2(\tau - \tau_o)} + \frac{1}{2} \log(1 - e^{-4(\tau - \tau_o)}),
\]

where \( \tau_o \) and \( A_o \) are two integration constants.

The two classes of supersymmetric solutions can be rewritten as expansions valid for \( 0 < \rho - \rho_o \ll 1 \).
The singularity at the equator of solutions in Eqs. (43) and (44), while the potential, and a maximum value of $\phi$ have been computed in Ref. [23]. We display our result in Fig. 9.

For the $(n=2)$ solutions $(\phi_2, A_2)$ we find

\[
\phi_2(\rho) = -\frac{3}{8} \log \left(\frac{9}{4}\right) + \frac{3}{2} \log(\rho - \rho_0) - \sqrt{\frac{2}{243}(\rho - \rho_0)^3} + \frac{17}{15701} \sqrt{\frac{2}{3}}(\rho - \rho_0)^6 + \cdots,
\]

(A7)

\[
A_2(\rho) = A_I + \log(\rho - \rho_0) + \frac{2}{27} (\rho - \rho_0)^3 - \frac{22}{5103} (\rho - \rho_0)^6 + \cdots.
\]

(A8)

and

\[
\phi_4(\rho) = -\frac{1}{2} \sqrt{\frac{3}{2}} \log \left(\frac{4}{3}\right) - \frac{1}{2} \sqrt{\frac{3}{2}} \log(\rho - \rho_0) + \frac{4}{15} \sqrt{2} (\rho - \rho_0)^{3/2} - \frac{28}{225} \sqrt{\frac{2}{3}} (\rho - \rho_0)^3 + \cdots,
\]

(A9)

\[
A_4(\rho) = A_I + \frac{1}{4} \log(\rho - \rho_0) + \frac{16}{15 \sqrt{3}} (\rho - \rho_0)^{3/2} - \frac{52}{675} (\rho - \rho_0)^3 + \cdots.
\]

(A10)

The $n=2$ case is the limit $\phi_o \to -\infty$ of the general DW solutions in Eqs. (43) and (44), while the $n=4$ case is recovered with the choice $\phi_o = -\frac{1}{2} \sqrt{\frac{3}{2}} \log \left(\frac{4}{3}\right)$ in Eqs. (46) and (47).

Both solutions exhibit a naked singularity in $D = 5$ dimensions, which softens in $D = 10$ dimensions. For the $n=2$ solutions $(\phi_2, A_2)$ we find

\[
R_{10,\bar{M}N}R_{10}^{\bar{M}N} = \frac{135}{4 \cos^2(\theta)(\rho - \rho_0)^3} + \cdots.
\]

(A11)

For the $(n=4)$ solutions given by $(\phi_4, A_4)$ the behavior of this invariant is milder,

\[
R_{10,\bar{M}N}R_{10}^{\bar{M}N} = \frac{5 \sin^4(2\theta)}{8 \sin^{10}(\theta)} + \cdots.
\]

(A12)

The singularity at the equator of $S^5$ displayed by the curvature invariant in Eqs. (A11) and (A12) at the end of space signals the incompleteness of the supergravity description in both supersymmetric cases.

The Wilson loops for the supersymmetric solutions have been computed in Ref. [23]. We display our result in Fig. 9 as a test of our procedure. In the case of the $n = 2$ solutions $(\phi_2, A_2)$, for both $\theta = 0, \pi/2$ we find a monotonic potential, and a maximum value of $L = L_{\text{max}}$. In the case $n = 4$ of $(\phi_4, A_4)$, there is a very major difference between the two cases with $\theta = 0, \pi/2$. The case of $\theta = 0$ displays the features expected by a first order phase transition, with long-distance screening. Conversely, for $\theta = \pi/2$ we find a linear potential at asymptotically large $L$, which is unbounded; this configuration has higher energy than the $\theta = 0$ one.

For the $n = 2$ solutions $(\phi_2, A_2)$ in Eqs. (A3) and (A4), the two-point function of the operator $O$ dual to the scalar $\phi$ can be found in Sec. 3.3 of Ref. [153] (see also Eq. (8.6) of Ref. [12]);

\[
\langle O(q)O(-q) \rangle = \frac{16}{3q^2} - 4(\psi(a(q)+1)-\psi(1)),
\]

(A13)

and for the tensors

\[
\langle T_{\mu\nu}T_{\rho\sigma} \rangle \propto \frac{q^2}{2\kappa'} \left[ \frac{1}{3} - \frac{q^2}{2} (\psi(a(q)+1)-\psi(1)) \right],
\]

(A14)

where $\psi$ is the digamma function, $q$ the four-momentum in Euclidean signature, $\kappa'$ is a constant, and $a$ is

FIG. 9. Energy $E_W$ as a function of the separation $L$, for supersymmetric solutions $n = 2$, $(\phi_2, A_2)$ (top) and $n = 4$, $(\phi_4, A_4)$ (bottom), and chosen to have $A_I = 0$. Continuous (blue) lines correspond to configurations with $\theta = 0$, short-dashed (red) lines depict configurations with $\theta = \pi/2$, and long-dashed (black) lines represent configurations reaching exactly the end of space.
The scalar correlator displays a massless pole, a gap and a continuum cut; the tensor differs by the absence of the massless state.

The \( n = 4 \) solutions \((\phi_d, A_4)\) in Eqs. (A5) and (A6), have a discrete spectrum, for example described in Eq. (26) of Ref. [147]. With \( j = 0, 1, \ldots \), the spectrum is given by \( M \propto \sqrt{j(j+1)/2} \approx 0, 1, 1.7, 2.5, 3.2, \ldots \). The spectrum of tensors can be found for example in Eq. (45) of Ref. [151], according to which it agrees with that of the scalars ‘… to an extremely good approximation …’, but for the fact that there is no zero mode.

The results of studying the Wilson loops agree with Figs. 1, 4, and 5, of Ref. [23]. We relied on numerical solutions guided by the asymptotic IR expansions, rather than using the exact solutions as in Ref. [23]. Our numerical study of the spectrum yields numerical results in splendid agreement with pre-existing calculations, as can be seen in Figs. 5 and 6. These results and their agreement with earlier studies of the supersymmetric solutions confirm the robustness of our formalism and numerical strategy.

APPENDIX B: EXPANSIONS FOR THE FLUCTUATIONS

In the numerical calculation of the spectra, we used the asymptotic expansions of the gauge-invariant fluctuations, as a way to optimize the decoupling of spurious cutoff effects present at finite \( \rho_2 \). In the case of DW solutions, we find that we can expand the physical fluctuations as follows:

\[
a^\phi = a^\phi_{2j} \log(z)^2 + a^\phi_z z^2 + O(z^4),
\]

\[
e^\nu = (e_0)^\nu \left( 1 - e^{-8A_4} - 4 q^2 z^2 - e^{-16A_4} \frac{q^4 \log(z)^4}{16} \right) + (e_4)^\nu z^4 + O(z^6),
\]

In these expressions, \( a^\phi_{2j}, a^\phi_z, (e_0)^\nu, \) and \( (e_4)^\nu \) are the integration constants governing the solutions of the second-order linearized equations, half of which are determined by the boundary conditions. In the probe approximation, the expansion for the scalars \( p^\phi \) is of the same form, up to \( O(z^4) \),

\[
p^\phi = p^\phi_{2j} \log(z)^2 + p^\phi_z z^2 + O(z^4). \tag{B3}
\]

The confining solutions do not satisfy the DW conditions. For the scalars we find

\[
a^\phi = a^\phi_{2j} \log(z)^2 + a^\phi_z z^2 + O(z^4), \tag{B4}
\]

\[
a^\chi = a^\chi_{0} \left( 1 - \frac{e^{-2A_4 z^2}}{4} q^2 z^2 - \frac{e^{-4A_4 z^2}}{16} q^4 \log(z)^4 \right) + a^\chi_4 z^4 + O(z^6), \tag{B5}
\]

where \( a^\phi_{2j}, a^\phi_z, a^\chi_{0}, \) and \( a^\chi_4 \) are the free parameters. For the probe approximation of the scalars, the free parameters are \( p^\phi_{2j}, p^\phi_z, p^\chi_0, \) and \( p^\chi_4 \), and as a result of mixing in the second derivative of the potential in Eq. (62) we have

\[
p^\phi = p^\phi_{2j} \log(z)^2 + p^\phi_z z^2 + O(z^4), \tag{B6}
\]

\[
p^\chi = p^\chi_{2j} \log(z)^2 + p^\chi_z z^2 + O(z^4). \tag{B7}
\]

For the tensor fluctuations we find

\[
e^\nu = (e_0)^\nu \left( 1 - \frac{1}{4} e^{-2A_4 + 2x_4} q^2 z^2 - \frac{1}{16} e^{-4A_4 + 4x_4} q^4 \log(z)^4 \right) + (e_4)^\nu z^4 + O(z^6). \tag{B8}
