Abstract: The genus Vitex, which belongs to the Verbenaceae family, includes approximately 250 species. Some species of the genus Vitex have traditionally been used for the treatment of headaches, ophthalmodynia, coughs, asthma, premenopausal syndrome, etc. Chemical investigations indicate that the characteristic constituents of the genus Vitex are terpenes, and 210 of these compounds, including monoterpenoids, sesquiterpenoids, diterpenoids and triterpenoids, have been obtained from 12 species. Pharmacological studies had shown that these terpenes possess anti-inflammatory, antitumor, antibacterial, antioxidant activities, and so on. In this paper, the identity of these terpenes and their pharmacological effects are reviewed, which can provide references for further research regarding the chemistry and utilization of the Vitex species.

Keywords: Vitex genus; chemical constituents; terpenes; pharmacological effects

1. Introduction

The genus Vitex is one of the largest genus in the Verbenaceae family, with approximately 250 species. It is widely distributed, but mainly found in the tropical areas with a few in subtropical regions. The plants are mostly shrubs or arbores [1]. Many species in the Vitex genus have significant medicinal effects. The fruits of Vitex trifolia L. var. simplicifolia Cham. and Vitex trifolia L. are named Manjingzi in the 2015 edition of Chinese Pharmacopoeia. Manjingzi is a traditional Chinese medicine with wind-heat-dispersing action used in treating headaches, migraines, premenopausal syndrome, etc. Chemical investigations indicate that the characteristic constituents of the genus Vitex are terpenes, and 210 of these compounds, including monoterpenoids, sesquiterpenoids, diterpenoids and triterpenoids, have been obtained from 12 species. Pharmacological studies had shown that these terpenes possess anti-inflammatory, antitumor, antibacterial, antioxidant activities, and so on. In this paper, the identity of these terpenes and their pharmacological effects are reviewed, which can provide references for further research regarding the chemistry and utilization of the Vitex species.
and triterpenoids being isolated and characterized from the genus. Pharmacological studies have shown that terpenes have anti-inflammatory, antitumor, antibacterial, antioxidant, hepatoprotective activities and so on. The goal of this review is to provide an overview of the chemical identities and the pharmacological effects of the terpenes isolated from species in the genus, which can serve as reference for further research and utilization of the *Vitex* species.

2. Chemical Constituents

So far, more than 200 terpenes have been obtained from the different parts of *Vitex* plants. Among these compounds, diterpenoids are the most dominant terpenes reported in the species. The names of terpenes, the corresponding plant sources and references from which they are derived are summarized in Tables 1–4. Their structures are shown in Figures 1–4.

2.1. Monoterpenoids and Sesquiterpenoids

2.1.1. Monoterpenoids

The majority of the monoterpenoids (Table 1, Figure 1) of the *Vitex* genus are iridoids and their corresponding glucosides (compounds 1–31). Beside the iridoids, two cineole-type monoterpenoid glucosides 32, 33 were obtained from the fruits of *Vitex rotundifolia* [5]. Moreover, Wu et al. [6] isolated an acyclic monoterpenoid vitexoid 34 from the fruits of *Vitex trifolia*.

Table 1. Monoterpenoids 1–34 isolated from plants of *Vitex* L.

2.1.2. Sesquiterpenoids

Apart from the monoterpenoids, only eight sesquiterpenoids 35–42 were found in the *Vitex* plants (Table 2, Figure 2). Among them, negunfurol (35) is a new sesquiterpenoid from *V. negundo* containing a furan ring [28]. Tiwari et al. [29] isolated three sesquiterpenoids 36–38 with furanoeremophilane.
skeletons from the stems of *V. negundo*. Meanwhile, aromadendrane-type sesquiterpenoids 39–42 have been obtained from *V. trifolia*, *V. agnus-castus* and *V. poligama* [17,18,30–33].

Table 2. Sesquiterpenoids 35–42 isolated from plants of *Vitex* L.

| No. | Compound Name                                      | Source | Reference |
|-----|----------------------------------------------------|--------|-----------|

| 42  | 4α,10α-Dihydroxyaromadendrane                     | f      | [33]      |

*a*: *Vitex negundo*. *b*: *V. trifolia*. *f*: *V. agnus-castus*. *i*: *V. poligama*.

2.2. Diterpenoids

Diterpenoids are abundant in the *Vitex* plants. The labdane-type diterpenoids 43–120 form the majority of the characterized diterpenoids, with the few others being norlabdane-type (compounds 121–132), halimane-type (compounds 133–141), abietane-type (compounds 142–151), clerodane-type (compounds 152–155) and isopimarane-type (compound 156). Commonly, diterpenoids of the genus exist in the form of aglycones, and only 65 and 66 are diterpenoid glucosides which are rare in *Vitex* genus [33,34]. Compounds 73, 74 and 75 are found as diterpenoid alkaloids containing an α,β-unsaturated-γ-lactam moiety, and these structures are unique in the genus [18,35,36]. Zheng et al. [37] isolated a 9,10-seco abietane diterpenoid negundoin F (151) and an isopimarane-type diterpenoid negundoin G (156) from an ethanolic extract of the seeds of *V. negundo*. The names of diterpenoids and their structures are listed and shown in Table 3 and Figure 3, respectively.
Table 3. Diterpenoids 43–156 isolated from plants of *Vitex* L.

Figure 3. Cont.
Figure 3. Structures of diterpenoids 43–156 isolated from *Vitex* L.
2.3. Triterpenoids

The triterpenoids isolated from the genus are mainly pentacyclic triterpenoids, consisting of oleanane-type (compounds 157–183), ursane-type (compounds 184–201), norursane-type (compounds 202–203), lupane-type (compounds 204–208) and friedelane-type (209). Only a few (compounds 162, 178, 181, 182, 195, 196) are triterpenoid glycosides [67,68]. Among them, cannabifolins A (184) and B (183) are the first examples of 12,19-epoxyursane- and oleanane-type triterpenoids and are rare natural pentacyclic triterpenoids with cis-fused C/D rings [69]. Tetracyclic triterpenoids like the 9-epi-cucurbitane-type 210 also has been isolated [43]. The names of these triterpenoids and their structures are listed in Table 4 and shown in Figure 4, respectively.

3. Pharmacological Effects

Terpenes isolated from Vitex plants have been evaluated for their anti-inflammatory, anti-tumor, antibacterial, antioxidant and other pharmacological effects, which provide potential explanations for their use in the treatment of various diseases in folk medicine. It was proved that terpenes were the principal active constituents for the aforementioned effects. A detailed summary of their pharmacological studies is given below.

3.1. Anti-Inflammatory Activity

Many plants from Vitex genus have been used for the treatment of inflammatory diseases. And pharmacological studies have also shown that some terpenes isolated from the genus have significant anti-inflammatory effects. Agnuside (3) exerted significant anti-inflammatory activity using carrageenan-, histamine- and dextran-induced acute inflammation models in rats. The inhibitory effect seemed independent of activation of the pituitary-adrenal axis because the inhibition effects against carrageenan-induced oedema in normal and adrenalectomized rats after oral administration of agnuside (3) were highly comparable. Furthermore, oral administration of agnuside (3) to arthritic rats can decrease the levels of intracellular interleukin-17 (IL-17) in lymphocytes with values of 12.17% and 11.04% at doses of 6.12 and 12.5 mg/kg, compared with non-agnuside-fed control groups 19.71% [20]. Twenty-four different compounds were isolated from V. rotundifolia by Lee et al., and their anti-inflammatory activities were tested by the Gries method. The results revealed that five diterpenoids (compounds 57, 61, 106, 141, 138) significantly inhibited nitric oxide (NO) production in lipopolysaccharide (LPS)-stimulated RAW 264.7 cells with the IC_{50} values of 11.3, 16.4, 17.2, 22.2 and 24.5 µM respectively, while the positive control aminoguanidine being 16.6 µM [45]. Li et al. [69] isolated fourteen triterpenoids from V. negundo var. cannabifolia, of which five compounds (192, 198, 159, 199, and 160) demonstrated moderate inhibitory effects on NO production, with IC_{50} values of 24.9 ± 4.6, 26.1 ± 3.6, 27.7 ± 3.3, 34.0 ± 4.1, 40.5 ± 4.9 µM, respectively. Zheng et al. [37] have isolated nine diterpenoids (compounds 97, 98, 123–125, 131, 145, 151, 156) from the seeds of V. negundo. Among these, negundoin C (125) and negundoin E (98) showed the most significant inhibitory effects on NO production using LPS-stimulated RAW 264.7 cells, with IC_{50} values of 0.12 and 0.23 µM, respectively, compared with the positive control indomethacin at 45.51 µM. Additionally, the authors demonstrated the protein expressions of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthetase (iNOS) with western blot analysis to describe the possible mechanism of their anti-inflammatory activity, and it was an interesting finding that the level of COX-2 protein and iNOS protein were decreased by 98 and 125.

3.2. Anti-Tumor Activity

It is also worth mentioning that some terpenes of the Vitex genus possess significant anti-tumor activities against several cancer cell lines. Wu et al. [6] isolated ten diterpenoids 34, 48, 53, 54, 79, 80, 137–140, including three new compounds 34, 48, 137, from V. trifolia L. All compounds were tested for their inhibitory effects on HeLa cell proliferation with the MTT assay, and their IC_{50} values ranged from 4.9 ± 0.5 to 28.7 ± 1.3 µM. Furthermore, vitetritolin I (137) exhibited significant inhibition effect with an IC_{50} value of 4.9 ± 0.5 µM, and induced cell cycle G_0/G_1 phase arrest and apoptosis of HeLa cells. Six terpenes 35, 37, 122, 188, 202, 203 were isolated from V. negundo and evaluated for their cytotoxicities against four cancer cell lines using the MTT method. The results revealed that negunurol (35) was the most active compound against HL-60, with an IC_{50} value of 0.94 ± 0.26 µg/mL and negundonorin A (202) was highly cytotoxic to ZR-75-30 cells with an IC_{50} value of 0.56 ± 0.19 µg/mL [28]. Mahesh et al. [35] isolated six diterpenoids 43, 53, 74, 75, 120, 138, including a new diterpenoid alkaloid 74, from V. agnus-castus. All compounds were evaluated for their cytotoxicities against the K562 cell line. The IC_{50} values ranged from 0.70 to 6.72 µg/mL, and compound 74 was the most cytotoxic, with an IC_{50} value of 0.70 µg/mL, compared with the
positive control cisplatin at 1.10 µg/mL. Corlay et al. [55] isolated nine labdane-type diterpenoids 67–72, 109–111 from V. vestita. All the diterpenoids except vitexolin A (110) were cytotoxic against the HCT-116 and MRC-5 cancer cell lines to some extent.

3.3. Antibacterial and Antifungal Activities

According to references [44,55,59,84], some terpenes in the Vitex genus possess significant antibacterial and antifungal activities. Vitexilactone C (49) showed weak antibacterial activity against Bacillus subtilis, Escherichia coli and Micrococcus tetragenus at the same minimum inhibitory concentration (MIC) value of 500 µg/mL [44]. The diterpenoid vitexolide A (69) isolated from V. vestita showed the most potent antibacterial activity against 46 Gram-positive strains compared with other diterpenoids 67, 68, 70, 109, 111. The MIC values ranged from 6 to 96 µM [55]. Epifriedelinol (209) is a pentacyclic triterpenoid isolated from Vitex peduncularis by bioassay guided separation. Its antibacterial activity was tested against 12 strains of Gram positive and Gram negative bacteria. The MIC values were in the range of 6.25–50 µg/mL. The minimum bactericidal concentration (MBC) values were in the range of 12.5–100 µg/mL [84]. Additionally, negundol (96), a labdane-type diterpeoid isolated from the seeds of V. negundo exhibited antifungal activity against Candida albicans (MIC80: 64 µg/mL), Cryptococcus neoformans (MIC80: 16 µg/mL) and Trichophyton rubrum (MIC80: 32 µg/mL) [59].

3.4. Antioxidant Activity

Results from different studies have demonstrated that many terpenes in the Vitex genus have significant antioxidant activities. Sridhar et al. [13] isolated six new acylated iridoid glucosides (compounds 17–22) from V. altissima, and each compound was tested for its superoxide radical-scavenging activity using the McCord and Fridovich method and 1-diphenyl-2-picrylhydrazyl (DPPH) radical-scavenging effect with the Lamaison method. The results showed three compounds 18–20 exhibiting significant antioxidant activity by both methods. Tiwari et al. [21] isolated iridoid glucosides agnuside (3), negundoside (23) and 6′-O-p-hydroxybenzoyl mussaenosidic acid (12) from V. trifolia. Compounds 3, 23 and 12 showed DPPH radical scavenging activities with IC50 values of 9.81, 9.96 and 10.31 µg, respectively, and also effectively inhibited NO radical at IC50 values of 12.90, 16.25 and 13.51 µg. Ferruginol (142), an abietane-type diterpenoid isolated from V. rotundifolia showed higher antioxidant activity than 3-tert-butyl-4-hydroxyanisole (BHA) using the ferric thiocyanate method. Furthermore, it has stronger DPPH radical scavenging effect equivalent to half that of L-cysteine [58].

3.5. Other Pharmacological Activities

Additionally, some of the terpenes also have analgesic, endocrinological, anti-hyperglycemic, antifeedant effects, etc. Okuyama et al. [15] verified the analgesic effect of two iridoids agnuside (3) and 10-O-vanilloylaucubin (4) by the acetic acid induced writhing test in mice. At a dose of 50 mg/kg compounds 3 and 4 exerted analgesic effects of 56% (p < 0.001) and 20% (p < 0.05), respectively. Extracts of V. agnus-castus have been used for amelioration of premenopausal syndrome, especially mastodynia, which were most likely caused by hypersecretion of prolactin. The proposed mechanism of action was due to dopaminergic and estrogenic principle. The mixture of clerodane-type diterpenoids (BNO-diterpenoids), isolated from 70% ethanolic extract of V. agnus-castus, showed the highest dopaminergic activity by reducing cyclic AMP (cAMP) formation and prolactin secretion [41]. Sundaram et al. [26] obtained the iridoid glucoside 23 from leaves of V. negundo, which could reduce the levels of blood glucose and glycoproteins, and increase the level of plasma insulin in streptozotocin diabetic rats. Compound 23 also showed anti-hyperlipidemic activity [27]. Additionally, hepatoprotective activity of some terpenes (compounds 23, 164) from genus Vitex plants was discovered by Indian scholars [24,75,85]. Ursolic acid (185) and betulinic acid (205) showed antifeedant activity against the larvae of Achoea janata [81].
4. Conclusions

In this review, we summarize the research progress on terpenes of the genus *Vitex* and their pharmacology. These findings indicate that this genus is a valuable source of bioactive molecules. Phytochemical and pharmacological studies of the compounds isolated from the genus *Vitex* have attracted more attention in recent years. Terpenes, including monoterpenoids, sesquiterpenoids, diterpenoids and triterpenoids were identified as the main chemical constituents of this genus. From the literature, there are approximately 250 species in the genus [1], but studies on terpenes had been done to some extent on only 12 species [9–21,30,55,56,62]. Considering the many bioactive terpenes isolated from the plants in this genus, further investigations on terpenes and their pharmacological effects of the other species are very necessary. In the pharmacology domain, most of the isolated terpenes have been evaluated for various activities in vitro without being further tested in vivo. Thus the promising pharmacological activities should be confirmed by in vivo assay using diverse rat models to prove them. In addition, taking into account their therapeutic efficiency, validating the relationships between chemical constituents, pharmacological effects and traditional uses of plants in this genus is still remains a fundamental task, and should be paid more attention to.

Acknowledgments: This work was supported by the National High Technology Research and Development Program of China (863 Program) (2013AA093001), the National Natural Science Foundation of China (81303142), the National Science Foundation for Post-doctoral Researchers (2015M570231) and the Tianjin City High School Science & Technology Fund Planning Project (20140147).

Author Contributions: Jin-Long Yao obtained literatures, classified the chemical constituents and drafted the structural formulas, wrote the manuscript; Shi-Ming Fang classified the chemical constituents and wrote the manuscript; Rui Liu classified the pharmacological literatures and revised the review critically for important intellectual content; Mahmood Brobbey Oppong modified the language; Er-Wei Liu managed references; Guan-Wei Fan contributed to conception and design of the review; Han Zhang obtained funding, overall responsibility.

Conflicts of Interest: The authors declare no conflict of interest.
