We report the successful synthesis of a "122" diluted ferromagnetic semiconductor with n-type carriers, Ba(Zn,Co)$_2$As$_2$. Magnetization measurements show that the ferromagnetic transition occurs up to $T_C \sim 45$ K. Hall effect and Seebeck effect measurements jointly confirm that the dominant carriers are electrons. Through muon spin relaxation ($\mu$SR), a volume sensitive magnetic probe, we have also confirmed that the ferromagnetism in Ba(Zn,Co)$_2$As$_2$ is intrinsic and the internal field is static.

I. INTRODUCTION

The combination of spin and charge degrees of freedom in diluted magnetic semiconductors (DMSs) makes them promising materials for spintronics. The observation of ferromagnetism in Mn doped III-V GaAs has therefore attracted extensive attention in the last two decades\textsuperscript{1-4}. (Ga,Mn)As films are typically fabricated via low-temperature molecular beam epitaxy (LT-MBE), where substitution of Mn\textsuperscript{2+} for Ga\textsuperscript{3+} introduces both spins and holes simultaneously. Despite the controversy about the origin of ferromagnetism in (Ga,Mn)As\textsuperscript{5}, it has been widely accepted that the itinerant carriers mediate the magnetic interaction between spatially separated magnetic ions. To date, the Curie temperature $T_C$ in (Ga,Mn)As has a maximum value of $\sim$ 190-200 K\textsuperscript{6-8}, which is still far below room temperature and therefore limits the possibilities for practical applications. Recently, a series of DMS materials that are structural derivatives of iron-based superconductors have been synthesized, including I-II-V Li(Zn,Mn)As\textsuperscript{9}, "1111" (La,Ba)(Zn,Mn)AsO\textsuperscript{10} and "122" (Ba,K)(Zn,Mn)$_2$As$_2$\textsuperscript{11}. Of these, (Ba,K)(Zn,Mn)$_2$As$_2$ has $T_C$ as high as 180 K\textsuperscript{11}. (Ba,K)(Zn,Mn)$_2$As$_2$ was synthesized through the doping of K and Mn into the parent semiconductor BaZn$_2$As$_2$, where the substitution of Mn for Zn introduces magnetic moments and the substitution of K for Ba introduces carriers. Considering that the end member BaMn$_2$As$_2$ is an antiferromagnet with a Neel temperature of 625 K\textsuperscript{12}, it seems possible that $T_C$ may reach room temperature in "122" systems when the synthesis conditions and the selection of elements are optimized\textsuperscript{13}.\textsuperscript{1}

The above-mentioned DMSs are all p-type, i.e., the dominant carriers are holes. N-type DMSs with electron carriers are still exceptionally rare. In practical applications, both p- and n-type DMSs are required to fabricate junctions and devices. Furthermore, n-type DMSs may shed light on the general mechanism for ferromagnetic ordering in DMSs. In the past, Co:ZnO films have been proposed to be a candidate for n-type DMS\textsuperscript{14-16}. However, the underlying mechanism is still under debate. For example, careful investigations showed that the ferromagnetism may arise from a hydrogen-facilitated interaction\textsuperscript{17}, metallic clusters\textsuperscript{18,19}, uncompensated spins at the surface of Co-rich antiferromagnetic nanocrystals\textsuperscript{20} or bound magnetic polarons\textsuperscript{21}. Co:TiO$_2$ films are also reported to possess ferromagnetism above room temperature, with electrons provided by defects or electric fields acting as carriers\textsuperscript{22,23}. A detailed resolved low-energy $\mu$SR investigation showed that Co:TiO$_2$ is fully magnetic with intrinsic ferromagnetism\textsuperscript{24}. Recently, Hai et. al. reported the observation of electron-mediated ferromagnetism in (In,Fe)As films where interstitial Be provides electrons\textsuperscript{25-27}. Similar fabrication routes have also been tried in (In,Co)As films, but no ferromagnetic ordering has been observed\textsuperscript{28}. Very recently, ferromagnetism above room temperature has also been reported in p-type (Ga,Fe)Sb and (In,Fe)Sb\textsuperscript{29,30}. Theoretically, Gu et. al. predicted that n-type DMSs may be realized in narrow-band-gap semiconductors\textsuperscript{31}.\textsuperscript{1}

In this paper, we demonstrate the successful synthesis of a high-quality n-type ferromagnetic semiconductor by doping Co onto the Zn sites of the narrow-band-gap (0.2 eV) semiconductor BaZn$_2$As$_2$\textsuperscript{32}. The highest $T_C$ of Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ reaches $\sim$ 45 K for $x = 0.04$. Using muon spin relaxation ($\mu$SR) measurements, we have confirmed the homogeneous and intrinsic nature of the ferromagnetic ordering in Ba(Zn,Co)$_2$As$_2$.\textsuperscript{1}

Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$
II. EXPERIMENTAL METHODS

A. Material synthesis.

Polycrystalline samples of Ba(Zn,Co)$_2$As$_2$ were synthesized via a solid state reaction of high purity elements ($\geq 99.9\%$) Ba, Zn, Co and As. Mixed ingredients were placed in alumina crucibles and sealed in evacuated silica tubes. All handling of the elements was conducted in a glove box filled with high purity Ar (the content of H$_2$O and O$_2$ is less than 0.1 ppm) except for the sealing of the silica tubes. The mixture was heated to 900 °C for 10 h, then held at 1150 °C for 24 h followed by cooling in the furnace. The products were then ground, pressed into pellets, sealed in evacuated silica tubes, and subsequently heated to 1150 °C and held for over 24 hours followed by fast cooling to keep the tetragonal phase.

B. Structural characterization.

Powder X-ray diffraction was performed at room temperature using a PANalytical X-ray diffractometer (Model EMPYREAN) with monochromatic Cu-K$_\alpha$ radiation. Energy-dispersive X-ray spectroscopy (EDX) was measured using a field emission scanning microscope (Model FEI SIRION-100).

C. Experimental characterization

DC magnetization measurements were conducted using a Quantum Design Magnetic Property Measurement System (MPMS3). The Hall effect and magnetoresistivity were measured using a Quantum Design Physical Property Measurement System (PPMS). The Seebeck coefficient was measured at room temperature using a commercial thermopower measurement apparatus. The zero field resistivity was measured via the typical four-probe method with a Keithley 6221 DC and AC current source and Keithley 2182A nanovoltmeter. $\mu$SR measurements were performed using the LAMPF spectrometer on the M20 beamline at TRIUMF, Canada, and $\mu$SR data were analyzed using the musrfit package$^{33}$.

III. RESULTS AND DISCUSSION

A. X-ray diffraction.

In Fig. 1(a), we show the X-ray diffraction patterns for Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ with different doping levels. In general, BaZn$_2$As$_2$ is polymorphic, typically crystallizing in either an orthorhombic structure (space group $Pnma$) or a tetragonal structure (space group $I4/mmm$)$^{11}$. The tetragonal structure results in a semiconductor with a band gap of $\sim 0.2$ eV$^{32}$ that forms the parent compound of the (Ba,K)(Zn,Mn)$_2$As$_2$ DMS system. In this structure, layers of {ZnAs$_4$} tetrahedra stack alternately with Ba layers along the c axis. We note that if the Zn atoms are replaced by Fe, the resulting material BaFe$_2$As$_2$ is the parent compound of many iron based superconductors$^{34}$. The X-ray diffraction peaks in Fig. 1(a) can be well indexed with a tetragonal structure (space group $I4/mmm$) with no sign of the orthorhombic phase or other impurities. In Fig. 1(b), we show the Rietveld refinement profile for the $x = 0.04$ sample using the GSAS-II package$^{35}$. No obvious impurity peaks were observed, and the resulting weighted reliability factor $R_{wp}$ is $\sim 9.87\%$, indicating a high sample quality. In Fig. 1(c), we show the lattice parameters of different doping levels. With increasing Co concentration a increases and c decreases monotonically. The monotonic behavior of the lattice parameters indicates the successful doping of Co up to $x = 0.05$. Higher doping does not produce a pure phase, which is also the reason why the resistivity of the $x = 0.05$ sample is larger than that of the $x = 0.04$ sample (see Fig. 5(a)).

B. Energy-dispersive X-ray spectroscopy

In Fig. 2, we show the surface morphology under scanning electron microscopy (SEM) and the energy spectroscopy of energy-dispersive X-ray spectroscopy (EDX) for Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ with $x = 0.04$. We select three different areas on the same sample and take the average results as the elemental composition. In Fig. 2(b), we show a typical EDX spectrum. Besides the low energy peaks which come from the elements C and O adhered on the surface, the other peaks are all indexed by Ba, Zn, Co and As. We tabulated the atomic percentages in Table. I. The ratio of Ba:(Co+Zn):As is close to the chemical formula, and the Co concentration, the ratio of Co:(Co+Zn), is $\sim 4.4\%$, which is consistent with our nominal doping level.

|       | Ba  | Zn  | Co  | As  |
|-------|-----|-----|-----|-----|
| First | 20.93 | 34.99 | 1.68 | 42.40 |
| Second| 20.81 | 37.28 | 1.67 | 40.23 |
| Third | 24.33 | 36.53 | 1.68 | 40.03 |
| Average| 22.02 | 36.27 | 1.68 | 40.03 |

C. Magnetic properties.

In Fig. 3(a), we show the temperature-dependent magnetization of Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ ($x = 0.01, 0.02, 0.03, 0.04, 0.05$) in an applied magnetic field of 100 Oe. Zero field cooling (ZFC) and
field cooling (FC) data are represented by open and filled symbols, respectively. For $x = 0.01$, no magnetic transition was observed down to the base temperature of 2 K, and the magnetic moment at 2 K in $H = 100$ Oe is only 0.005 $\mu_B$/Co. However, for Co concentrations exceeding 1%, a sudden increase of the magnetization develops around 35-45 K, indicative of a ferromagnetic transition.

We used the Arrott plot method for the precise determination of the Curie temperature $T_C$ for Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$. In Fig. 3(e), we show the Arrott plot for $x = 0.05$. Around $T_C$, the points in high magnetic field fall approximately on a series of parallel lines. The solid lines displayed on the plot are the linear fits at high magnetic field, and the nonlinear behavior at low field is ascribed to the higher-order terms we omitted from the analysis or other deviations from mean field theory. We identify $T_C$ as 41 K, the temperature at which the parallel line would pass through the origin. $T_C$ for other doping levels was also determined by this method (see Supplement). We list $T_C$ for Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ in Table II. We also obtained the effective moments $\mu_{eff}$ by fitting the temperature dependent magnetization above $T_C$ with a modified Curie-Weiss law: $\chi = \chi_0 + C/(T - \theta)$, where $\chi_0$ is the temperature independent component, $C$ is the Curie constant and $\theta$ is the Weiss temperature, $\mu_{eff}$ is $\sim 1.1-1.7 \mu_B$/Co. According to $\mu_{eff} = \mu_B g \sqrt{S(S+1)}$, where $\mu_B$ is the Bohr magneton and assuming the Lande factor $g = 2$, we estimate the average spin state of Co to be close to $S = 1/2$. Due to the contribution of holes and interstitial Mn, the magnetic moment of Mn in (Ga,Mn)As from magnetization measurements has also been reported to be less than the expected value of $5\mu_B$/Mn.

In Fig. 3(b), we show the isothermal magnetization at 2 K. Clear hysteresis loops are observed for all doping levels except the paramagnetic $x = 0.01$ sample. The coercive field of Ba(Zn,Co)$_2$As$_2$ is on the order of $\sim 10$ Oe, which is much smaller than the value of 1 T in (Ba,K)(Zn,Mn)$_2$As$_2$. The small coercive field is consistent with the minimal bifurcation of ZFC and FC curves at 100 Oe shown in Fig. 3(a). In Fig. 3(c), we show the temperature dependence of the hysteresis loop for $x = 0.04$. With increasing the temperature, the moment become smaller and the hysteresis loop eventually disappears above 50 K. The saturation moment $\langle \mu_s \rangle$ is $\sim 0.2 - 0.3 \mu_B$/Co for Ba(Zn,Co)$_2$As$_2$ which is much smaller than $2\mu_B$/Mn for (Ba,K)(Zn,Mn)$_2$As$_2$ and $5\mu_B$/Mn for (Ga,Mn)As.

### Hall effect, Seebeck effect and transport.

We jointly utilized measurements of the Hall effect and Seebeck effect (see Supplement) to investigate the properties of the carriers. Since $R_{Hall} = B/(ne)$, where $B$ is the external field perpendicular to the current and $e$ is the elementary charge, we obtained the carrier con-
Figure 3: Magnetization results. (a) The temperature-dependent magnetization of Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ ($x = 0.01, 0.02, 0.03, 0.04, 0.05$) in a magnetic field of 100 Oe. The open and filled symbols represent the zero-field-cooled and field-cooled data, respectively. Inset: Plot of $1/(\chi - \chi_0)$ versus $T$. Straight lines represent a Curie-Weiss fit. (b) The isothermal magnetization of Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ ($x = 0.01, 0.02, 0.03, 0.04, 0.05$) at 2 K in an applied magnetic field ranging from -200 Oe to 200 Oe. (c) Evolution of the hysteresis loop of Ba(Zn$_{0.96}$Co$_{0.04}$)$_2$As$_2$ with increasing temperature. (d) Isothermal magnetization of Ba(Zn$_{0.95}$Co$_{0.05}$)$_2$As$_2$ at different temperatures. (e) The Arrott plot for Ba(Zn$_{0.95}$Co$_{0.05}$)$_2$As$_2$ at different temperatures. Lines show the best linear fit.
centrations from $R_{Hall}$ versus $B$ curves. In Fig. 4, we show the representative Hall resistivity ($R_B$) at 25 K and the variation of carrier density ($n$) versus temperature ($T$). Ideally, we should observe the anomalous Hall effect below $T_C$, but the signal to noise ratio is poor in the measurement. Nonetheless, the negative slope of the Hall resistivity curve indicates that the dominant carriers in Ba(Zn,Co)$_2$As$_2$ are electrons. The carrier concentration is roughly estimated to be $10^{17} \sim 10^{18}$ cm$^{-3}$ depending on the measured temperature. This low carrier concentration is comparable to that of Li(Zn,Mn)P and indicates that the electrons introduced by Co doping are mostly localized. The carrier density decreases gradually with decreasing temperature. Seebeck effect measurements at room temperature were also conducted to investigate the carrier type (see Supplement). The Seebeck coefficient is $S = -\Delta U/\Delta T$, where $\Delta U$ is the voltage difference between two electrodes and $\Delta T$ is the temperature difference. The sign of the Seebeck coefficient is related to the carrier type, positive for p-type carriers and negative for n-type carriers. The room temperature Seebeck coefficient is $\sim -16$ $\mu$V/K for $x = 0.04$ and $\sim -7$ $\mu$V/K for $x = 0.05$. The negative Seebeck coefficient confirms our conclusion of n-type carriers.

In Fig. 5(a), we show the electrical transport properties for different doping levels. With Co doping, the resistivity retains its semiconducting behavior but the magnitude decreases, indicating the successful introduction of carriers by Co substitution for Zn. In Fig. 5(b), we show the resistivity in different magnetic fields ($R(H)$) for the $x = 0.04$ sample. The $R(H)$ curve decreases clearly below $T_C$, which is due to the suppression of magnetic scattering by the external field. At $T = 2$ K, $R(H)$ reaches a minimum at $H = 6000$ Oe with $(\rho - \rho(0))/\rho(0)$ reaching $\sim -17\%$, as shown in the inset of Fig. 5(b). This value is much larger than the value of $\sim 7.5\%$ for (Ba,K)(Zn,Mn)$_2$As$_2$ at 7 T. Above 6000 Oe, $R(H)$ displays a slight increase with increasing external field. This positive $R(H)$ is from the field-induced spin splitting on disorder-modified electron-electron interactions that has been observed in n-type (Zn,Co)O. Nonetheless, the high sensitivity of the resistivity to magnetic field indicates that the electrical transport properties of Ba(Zn,Co)$_2$As$_2$ can be easily controlled by external magnetic field.

E. ZF- and LF-$\mu$SR.

Generally speaking, a small amount of magnetic impurities such as Co nanoparticles or unknown Co compounds can give rise to magnetic signals, which may obscure the intrinsic magnetic properties. To rule out such a scenario, we performed $\mu$SR, a volume-sensitive magnetic probe, to investigate Ba(Zn,Co)$_2$As$_2$. In Fig. 6(a), we show the zero field (ZF-) $\mu$SR time spectra for Ba(Zn$_{0.95}$,Co$_{0.05}$)$_2$As$_2$. A fast-relaxing component clearly arises below $T_C$, consistent with the formation...
Table III: Comparison of selected properties of (Ga,Mn)As, (Ba,K)(Zn,Mn)$_2$As$_2$ and Ba(Zn,Co)$_2$As$_2$.

| Valence before doping | (Ga,Mn)As | (Ba,K)(Zn,Mn)$_2$As$_2$ | Ba(Zn,Co)$_2$As$_2$ |
|-----------------------|-----------|-------------------------|-------------------|
| Carrier type          | III-V     | II-II-V                 | II-II-V           |
| Maximum $T_C$         | 190 K$^6$ | 180 K$^{11}$            | 45 K              |

| Sample form           | thin film | bulk form               | bulk form         |

Figure 6: Results of $\mu$SR characterization. (a) ZF-$\mu$SR time spectra of Ba(Zn$_{0.95}$Co$_{0.05}$)$_2$As$_2$. The solid lines show the best fit to the dynamic-static relaxation function with the static local field amplitude parameter $a_s$ shown in (b) and the dynamic relaxation rate parameter $\lambda_d$ shown in (d). The LF-$\mu$SR time spectra are shown in (c), exhibiting full decoupling at 200 Oe. (e) The time spectra of LF-$\mu$SR in Ba(Zn$_{0.95}$Co$_{0.05}$)$_2$As$_2$ with an external field of 100 Oe at different temperatures. (f) The muon spin relaxation rate $1/T_1$.

Figure 7: Plot of $a_s$ versus $T_C$. Correlation between the static internal field parameter $a_s$ determined at $T = 2$ K by ZF-$\mu$SR versus the ferromagnetic Curie temperature $T_C$ observed in (Ga,Mn)As$^{13}$, Li(Zn,Mn)As$^3$, Li(Zn,Mn)P$^{43}$, (La,Ba)(Zn,Mn)AsO$^{10}$, (Ba,K)(Zn,Mn)$_2$As$_2$$^{11}$, and Ba(Zn,Co)$_2$As$_2$ (current study). A factor 4/3 is multiplied to the parameter $a_s$ to adjust the difference from the simple exponential decay rate $\Lambda$ adopted in (Ga,Mn)As$^{13}$.
ZFC and FC curves start to bifurcate as shown in Fig. 3(a). This temperature should be related to the freezing of magnetic domains.

**F. Discussion**

When we plot the static internal field parameter $a_s$ versus $T_C$ in Fig. 7, the point for the present n-type system lies at a location very different from the linear trend shown by many other p-type DMS systems\(^9_{-11,43,44}\). Since the static internal field parameter $a_s$ is proportional to the concentration multiplied by the average static moment size in dilute spin systems, the trend for the n-type system implies that $T_C$ is relatively high for the given size and density of the static ordered moments. This tendency can be partly ascribed to the difference in the given size and density of the static ordered moments.

This feature may be helpful for obtaining higher coercive field and stronger ferromagnetic coupling in the n-type system compared to the p-type Mn doped DMS systems, which involve frustration. This is because the nearest-neighbor Mn pairs are coupled antiferromagnetically, as can be seen in BaMn$_2$As$_2$ being a strong antiferromagnet with $T_N \sim 625$ K\(^12\). In contrast, BaCo$_2$As$_2$ is a paramagnet showing a tendency towards ferromagnetic correlations\(^15,50\). Therefore, there is no frustration between neighboring Co spins in the Co-doped "122" system. This could lead to the smaller coercive field and stronger ferromagnetic coupling in the n-type system compared to the p-type Mn doped DMS system. This feature may be helpful for obtaining higher $T_C$ in n-type DMS systems. Another concern we should note is that the superparamagnetic-like fragments caused by the fluctuations of the carrier density\(^46-49\). If the dynamic frequency of these superparamagnetic-like fragments is smaller than the lower frequency limit of $\mu$SR that is \(\sim 10^4\) Hz, $\mu$SR will treat them static.

The n-type DMS Ba(Zn,Co)$_2$As$_2$ ($T_C = 45$ K) from the current study joins several related compounds including the p-type DMS (Ba,K)(Zn,Mn)$_2$As$_2$ ($T_C = 180$ K, see Table III\(^11\), the Fe-based superconductor Ba(Fe,Co)$_2$As$_2$ ($T_C = 25$ K)$^{34}$, the antiferromagnetic insulator BaMn$_2$As$_2$ ($T_N = 625$ K)$^{12}$, and the paramagnetic metal BaCo$_2$As$_2$\(^50\). They all share a common tetragonal crystal structure with a lattice mismatch of less than 5%. Superconducting films of Ba(Fe$_{1-\delta}$Co$_{\delta}$)$_2$As$_2$ have been fabricated successfully using pulsed laser deposition methods by many groups\(^51\). Recently, Xiao et al have successfully grown high-quality epitaxial films of the tetragonal $\beta$-BaZn$_2$As$_2$\(^32\), and Cao et al are working on the growth of Ba(Zn,Co)$_2$As$_2$ films\(^32\). With the progress of thin film growth, it is conceivable that various junctions and devices can be fabricated to combine n-type DMS Ba(Zn,Co)$_2$As$_2$, p-type DMS (Ba,K)(Zn,Mn)$_2$As$_2$, and the superconductor Ba(Fe,Co)$_2$As$_2$ through the As layers.

**IV. CONCLUSION**

We have successfully synthesized the ferromagnetic semiconductor Ba(Zn,Co)$_2$As$_2$ via the solid state reaction method. Hall resistivity and Seebeck coefficient measurements jointly confirmed that the carriers in Ba(Zn$_{1-x}$Co$_x$)$_2$As$_2$ are electrons. Magnetization measurements show that the highest $T_C$ is \(\sim 45\) K for the 4% doping level and the coercive field is on the order of 10 Oe. ZF- and LF-$\mu$SR measurements show that a static field arises throughout the full sample volume below $T_C$, with a magnitude of about 10 Oe at the muon stopping sites. In the temperature-dependent LF-$\mu$SR measurements, we observe a critical slowing down of spin fluctuations around $T_C$ and the freezing of magnetic domains at a lower temperature. Combining the ZF- and LF-$\mu$SR time spectra, we conclude that the present n-type DMS system exhibits characteristic signatures of dynamic slowing down followed by static magnetic order, with a magnetically ordered state in the entire volume within the time/frequency window.
