1. Introduction

Bassiatin ((3R,6R)-3-benzyl-4-methyl-6-propan-2-ylmorpholine-2,5-dione) (Fig. 1) is a newly discovered morpholine-based depsipeptide which is produced by some soil-sourced fungi, including entomopathogenic and phytopathogenic species (Keller et al., 2005). Bassiatin is reported to be a platelet aggregation inhibitor (Kagamizono et al., 1995), and its stereoisomer, lateritin (3-benzyl-4-methyl-6-propan-2-ylmorpholine-2,5-dione), had an inhibitory effect on the growth of some human cancer cell lines, Gram-positive bacteria and Candida albicans (Pettit et al., 2010). Bassiatin is also found to be an antibacterial agent on methicillin-resistant Staphylococcus aureus (Keskin et al., 2016). Recent studies show that bassiatin inhibits cell proliferation and cell cycle progression on MCF-7 breast cancer cell line by repressing cyclin D1 expression and inducing apoptosis via activation of the ERK-MAPK pathway (Meng et al., 2011, Meng et al., 2012). Furthermore, it is also reported that bassiatin has an antiestrogenic effect on MCF-7 Estrogen Receptor α (ERα) positive breast cancer cell line. However, the results of these studies didn’t show the comparison between bassiatin and today’s antiestrogenic agents in terms of cytotoxic activity. In addition, it has not been totally understood that bassiatin has only hormone-based inhibition.

Cancer which is regarded as the disease of our age varies because of its different foci depending on environmental and genetic factors. When we look at the world average, it is known that the most frequent and high-mortality cancer in women is breast cancer (Jemal et al., 2011). Although many important advances have been made for early detection and effective treatment of breast cancer, breast cancer-induced mortality rates have increased over the past 30 y (Al-Hajj et al., 2003).

In vitro studies on inhibition capability of fungal-sourced bassiatin versus tamoxifen against ERα, EGFR and VEGFR on breast cancer cells

ABSTRACT

Bassiatin which is produced by some fungi, is morpholine-based depsipeptide. Recent studies show that bassiatin inhibits MCF-7 breast cancer cell proliferation with its anti-oestrogenic effect. In this study, bassiatin’s inhibition versus Tamoxifen was examined by comparing the effects on epidermal growth factor receptor and vascular endothelial growth factor receptor in addition to oestrogen receptor on breast cells. For this purpose, 15 concentrations of bassiatin, tamoxifen and combination of both were treated in terms of cytotoxicity on MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines. For cell cycle analyses, MCF-7 and SVCT cell lines were incubated with 37.5 μM bassiatin, tamoxifen and combined substance for 24 h and 48 h. After treatment, cell distribution in each phase of the cell cycle was measured with flow cytometer. Furthermore, each interaction related to receptors were investigated with immunoassay ELISA kits. As a result, bassiatin-induced MCF-7 cell cycle arrest was shown in G0/G1 and G2/M phases at the presence of bassiatin. It was also found that bassiatin is more effective at all examined receptors on breast cancer cells than tamoxifen. These results show that bassiatin can be used effectively in breast cancer treatment as a new anticancer agent because of its multiple inhibition effects.

Keywords: cell cycle; MCF-7; SVCT

1. Introduction

Bassiatin ((3R,6R)-3-benzyl-4-methyl-6-propan-2-ylmorpholine-2,5-dione) (Fig. 1) is a newly discovered morpholine-based depsipeptide which is produced by some soil-sourced fungi, including entomopathogenic and phytopathogenic species (Keller et al., 2005). Bassiatin is reported to be a platelet aggregation inhibitor (Kagamizono et al., 1995), and its stereoisomer, lateritin (3-benzyl-4-methyl-6-propan-2-ylmorpholine-2,5-dione), had an inhibitory effect on the growth of some human cancer cell lines, Gram-positive bacteria and Candida albicans (Pettit et al., 2010). Bassiatin is also found to be an antibacterial agent on methicillin-resistant Staphylococcus aureus (Keskin et al., 2016). Recent studies show that bassiatin inhibits cell proliferation and cell cycle progression on MCF-7 breast cancer cell line by repressing cyclin D1 expression and inducing apoptosis via activation of the ERK-MAPK pathway (Meng et al., 2011, Meng et al., 2012). Furthermore, it is also reported that bassiatin has an antiestrogenic effect on MCF-7 Estrogen Receptor α (ERα) positive breast cancer cell line. However, the results of these studies didn’t show the comparison between bassiatin and today’s antiestrogenic agents in terms of cytotoxic activity. In addition, it has not been totally understood that bassiatin has only hormone-based inhibition.

Cancer which is regarded as the disease of our age varies because of its different foci depending on environmental and genetic factors. When we look at the world average, it is known that the most frequent and high-mortality cancer in women is breast cancer (Jemal et al., 2011). Although many important advances have been made for early detection and effective treatment of breast cancer, breast cancer-induced mortality rates have increased over the past 30 y (Al-Hajj et al., 2003).

Even if drugs used in hormonotherapy or chemotherapy are treated individually or in combination to the patient for the effective treatment of breast cancer, the disease process can result in death (Muss et al., 1991). Many drugs have been used in the active treatment of breast cancer as in many diseases in recent years. These drugs include doxorubicin, docetaxel, anastrozole, and tamoxifen (Andre et al., 2004). The treatment of breast cancer is changing and developing together with these drugs and the newly discovered specific cytotoxic agents and so that more positive results are obtained on breast cancer. In today’s conditions, successful results are generally obtained with the protocols used in the treatment of breast cancer, but medicines used in treatment sometimes cause metabolic disorders and side effects on normal tissues and organs. In addition, after intensive use of drugs, the development of resistance to drugs can also be observed and the treatment may fail. The high cost and market value of today’s drugs have led to the discovery of alternative anti-tumour agents. Since fungi produce a wide range of natural products that have antimicrobial and anti-tumour effects, many fungal products are produced industrially (Huang et al., 2008).

In ERα-positive breast cancer cells MCF-7, ERα plays a domiinant role in cell proliferation (Ruff et al., 2000, Ikeda & Inoue, 2004). But it is known that there are also different focuses to affect the cell proliferation except for oestrogen. The effects of Epithelial Growth Factor and Vascular Endothelial Growth Factor on breast cancer formation have been known since approximately 15 y. Epithelial Growth factor shows its effect by binding Epithelial Growth Factor Receptor (EGFR) which is found most breast cancer cells and cancerous cells grow and multiply with these interactions (Olayioye, 2001, Walker & Dearing, 1999). Vascular Endothelial Growth Factor is produced by breast carcinoma cells to stimulate angiogenesis and contribute the spread of cancer by binding Vascular Endothelial Growth Factor Receptor (VEGFR) (Guo et al., 2003). When EGFR and VEGFR express in these tumour types, tumours cannot respond to endocrine treatments and the lifespan of the patient decreases. EGFR and VEGFR’s are found breast cancer cell lines both ER-negative (MDA-MB-231, SK-BR-3 and HS578T) and ER-positive (MCF-7, T47D and ZR-75-1) (Olayioye, 2001, Guo et al., 2003). Therefore, it is expected that the agent to be used effectively in breast cancer treatment should have both antiestrogenic effect and other receptor-based (EGFR and VEGFR) inhibition capability.

The aim of this study is to investigate the inhibition capability of bassiatin against EGFR and VEGFR on MCF-7 (ER+, PR+, HER2/Neu-) breast cancer cell lines besides its antiestrogenic effect with comparing MDA-MB-231 (ER-, PR-, HER2/Neu-) and SK-BR-3 (ER-, PR-, HER2/Neu++) breast cancer cell lines and SVCT non-tumorigenic normal breast epithelium cell line. Furthermore, the efficacy of bassiatin on breast cancer cell lines have been investigated compared to standard SERM tamoxifen active substance which is currently used in hormonotherapy, one of the breast cancer treatment. It has been also evaluated whether the combined use of bassiatin and tamoxifen increases inhibitor effectiveness.

2. Materials and methods

2.1. Bassiatin production.

Beauveria bassiana (KVL-03129 strain given by Nicolai V. Meyling from The Royal Veterinary and Agricultural University, Copenhagen, submitted to ARSEF (Catalog of Species); GenBank Accession Number: ASM168263v1) was selected to obtain a high amount of bassiatin. Bassiatin was produced in a 250 mL shaking liquid medium containing 0.3% yeast extract, 0.3% malt extract, 0.5% peptone, 2% glucose, 0.05% KH₂PO₄ and 0.05% NH₄Cl at pH 6.5 under 28 ℃ for 9 d using B. bassiana (Meng et al., 2011). The culture broth was filtered with the help of Büchner funnel using sterile Whatman No.1 filter paper and the same amount of ethyl acetate (EtOAc) was treated with culture broth. This mixture was extracted by using the separated funnel. EtOAc extract was evaporated with Rotary evaporator (Heidolph, Laborota 4000, Schwabach) under pressure. The residue obtained from the evaporation stage contains bassiatin and other organic chemicals. The residue was dissolved with the minimal amount of chloroform (CHCl₃) and prepared for 2-staged chromatography. In the first stage, the dissolved residue was added to the Sephadex-filled (Cytiva, G-25, Superfine, Bucinaco) column and substances within the colon were eluted with 50:50 rated CHCl₃,MeOH (Chloroform-Methanol) mixture. The separation of bassiatin from other compounds was provided with the second chromatography process by using silica gel-filled (60 Å, 0.015-0.040 mm, Merck) column and bassiatin was eluted with CHCl₃,MeOH (65:35) mixture. For the purification of pure and high-yielded bassiatin, Preparative HPLC (Agilent Technologies, 1260 Infinity, California) was done by using 100-5-C18 (4.0 x 100 mm) specific column (Kromasil®, Munich). Bassiatin-contained elution was prepared with MeOH:Water (80:20) mixture and it is processed in 98 bar pressure at 4 mL/min within the HPLC device. The peak range of bassiatin was seen at 2.681 min and found to be higher than 800 mAU. End of the process, pure bassiatin was collected at the collection part of the HPLC device (Meng et al., 2011). The purity of obtained bassiatin was determined by evaluating H NMR and C NMR spectrum data with 400MHz AV model NMR spectrometer (Table 1).

| Table 1 | 1H and 13C NMR chemical shifts of bassiatin (3R,6R) |
|---|---|
| 13C (ppm) | 1H (ppm) |
| C-2 | 171.55 |
| C-3 | 61.47 4.57 (1H, t, J=6.571 Hz) |
| C-5 | 170.94 |
| C-6 | 79.4 5.59 (1H, d, J=3.588 Hz) |
| C-7 | 30.66 2.10 (1H, sept, J=6.542 Hz, 3.588 Hz) |

2.2. Cell lines and cell culture

For this study, MCF-7 (ER+, PR+, HER2/Neu-), MDA-MB-231 (triple-negative: ER-, PR-, HER2/Neu-) and SK-BR-3 (ER-, PR-, HER2/Neu++) as breast cancer cell lines and SVCT as a non-tumorigenic normal breast epithelial cell line were selected. Cell lines which are stocked in the freezer were firstly cultivated for cytotoxicity tests. The culture medium used for the cultivation of MCF-7 and MDA-MB-231 cell lines (ATCC) contains DMEM/F12 (Dulbecco’s modified Eagle’s medium) + 2 mM Glutamine + 10% Foetal Bovine Serum (FBS) + penicillin/streptomycin while the culture medium of SK-BR-3 cell line contains McCoy’s 5A with + 2 mM Glutamine + 10% Foetal Bovine Serum (FBS) + penicillin/streptomycin. All breast cancer cells were incubated at the standard conditions (5% CO₂, 37 ℃).

SVCT cell line was purchased from The European Collection of Authenticated Cell Cultures (ECACC 94122105). SVCT has been established from human breast epithelial cells being transfected with SV40. GMO status is showed as Genetically Modified Organ.
ism Class 1. SVCT have been found positive for the expression of keratin 7, 8 and 18 but negative for keratin 19. Epithelial cells, dome formation when confluent. SVCT cell line needs specific compounds in its culture medium; DMEM + 2 mM Glutamine + 5 μg/mL Hydrocortisone + 10 μg/mL Insulin + penicillin/streptomycin + 10% FBS.

2.3. Cytotoxicity studies

Cytotoxicity of bassiatin was determined by using MTT assay which evaluates metabolic activities of cells with a colorimetric method. In this study, toxicities of obtained bassiatin and tamoxifen active substance on MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines were investigated and toxic doses of these substances were determined. Because of the widespread use of combined drug therapy in cancer treatments, the cytotoxic effect of the combined substance prepared in 1:1 ratio with bassiatin and tamoxifen has been investigated on all cell lines. Within these scopes, produced cell lines were collected with trypsinization from flasks and then centrifuged. Pellets were used to prepare cell suspensions and cell counting was done to determine the number of cells in each suspension. For cell counting; 900 μL cell suspension was transferred to the eppendorf tube which has 100 μL Trypan blue (0.5% w/v, Biochrom, Cambridge) inside. Vital cell counting was performed with this suspension using an improved Neubauer slide under the light microscope (Leica, DM750, Wetzlar). Cytotoxicity study was prepared by inoculating 1×10^5 cell/well in 96-well plates. After 24 h in the standard incubation conditions, medium cultures in wells were discarded and substances which will be tested in terms of cytotoxicity were added to the wells. It was used different 96-well plates for each incubation period (24, 48 and 74 h) and each substance which will be tested in this study. 15 different concentrations (0.25, 0.5, 1.25, 2.5, 3.75, 5, 6.25, 7.5, 12.5, 18.75, 25, 37.5 and 75 μM) were prepared for each concentration and these concentrations were used as a 6 repeated in cytotoxicity studies. Six wells were evaluated as a control group in each 96-well plate.

For MTT analyses, MTT solvent was prepared with 1:10 rated MTT:Serum-free medium. After incubation with substances, medium cultures in wells were discarded, 200 μL MTT solvent (5 mg/mL) was added in each well and plates were incubated in dark 5% CO₂ and 37 °C conditions for 4 h. MTT solvent was discarded from each well after incubation. 100 μL isopropyl alcohol containing 0.05 N HCl was added in each well and reading was performed with ELISA reader (Biotech, μQuant, Vermont) which is adjusted to 570 nm. Obtained data were used for statistical studies.

2.4. Cell imaging

Based on cytotoxicity studies, wells were prepared with the same concentrations of substances for imaging of substance-based inhibition and apoptosis of cells with florescent dying and imaging was made daily. 50:50 rated Acridine Orange/Propidium Iodide (AO/PI) florescent dye mixture was used for imaging. For this purpose, medium cultures in wells were collected and each well was washed with 10 × Phosphate-buffered saline (PBS). 100 μL AO/PI was treated to cells in washed-wells for 20 s. After collecting dye, wells were washed with PBS in 10 s and imaged with florescent microscope (Olympus, Waltham).

2.5. Detection of apoptotic cells with propidium iodide (PI) and cell cycle analyses

The apoptosis situation of MCF-7 and SVCT cell lines and cell cycle analyses were conducted at Cancer Institute of Hacettepe University. Apoptosis was detected using PI florescent dye. After 24 and 48 h incubation of MCF-7 and SVCT cells with 37.5 μM bassiatin, tamoxifen and combined substance, 1 mL PBS and 2 mL 99% purely ethanol was added drop by drop on 1.5×10^5/mL cells respectively and cells were fixed. Following an incubation at + 4 °C for a night, cells were washed twice with PBS and 70 μL RNase and 100 μL PI were added on cells. After incubation in dark at room temperature for 30 min, late apoptosis and cell cycle analyses were done by counting 10,000 cells with flow cytometry (Beckman Coulter EPICS XLMCL, California). The SubG1 peak which shows DNA fragmentation was evaluated for late apoptosis. It is thought that cell cycle evaluation has also contributed to the study. G0/G1, Synthesis and G2/M rates were calculated from two-variable histograms with Multicycle software program (Phoenix system, San Diego) for cell cycle analyses (Deeb et al., 2007, Meng et al., 2011).

2.6. Quantitative measurement of ERα, EGFR and VEGF

Interactions of bassiatin with receptors to which bind oestrogen alpha (α), epithelial growth factor (EGF) and vascular endothelial growth factor (VEGF) that influence the growth and development of breast cancer cells were investigated in the MCF-7 and SVCT cell line and the amounts of these receptors has been identified comparatively in cells. Cellular extracts were obtained for ERα, EGFR and VEGF analyses using commercial quantitative immunooassay kits.

In the quantitative measurement of ERα, the study was carried out in accordance with the protocol of the purchased ELISA kit (Abcam, ab128499, Cambridge). Nuclear extracts of cells were used at this stage. Dilution buffer containing 50 μg nuclear extracts was added to the microplates supplied in the assay kit and sample wells were prepared for each nuclear extract. The MCF-7 nuclear extract in the manufacturer’s kit was added to the control wells as a positive control. After 1 h of incubation at room temperature on a shaking platform, each well was washed 3 times with 1 × wash buffer and primary detection antibodies were added to them (30 μL ERα antibody). After 1 h of incubation on the shaking platform again, each well was washed 3 times with 1 × wash buffer and treated with 50 μL of HRP-conjugated secondary antibodies. The previous procedure was repeated and the colorimetric reaction with 100 μL of the developing solution was performed. The procedure was terminated with 100 μL of stop solution. At this stage, the presence of acid is determined by the blue colour turning yellow. Measurements were made at 450 nm using an ELISA reader to read the absorbance. The results obtained by the manufacturer firm in the validation studies using this kit were evaluated as a reference.

Commercial ELISA kits have also been used to quantitatively determine EGFR and VEGFR (Abcam, ab192148 ab193764, Cambridge). The preparation of cell extracts and ELISA test protocol for both are the same. In preparing the cell extract for EGFR and VEGFR, the direct lysis was preferred from the adherent cells. 50 μL of each cell extract was added in the determined wells of the microplate supplied in the assay kit. 50 μL of antibody cocktail was added to each well. Incubation was done for 1 h at room temperature on shaking platform and each well was washed with wash buffer. Subsequently, 100 μL of TMB substrate was added to each well and incubated in a dark at 400 rpm for 10 min on shaking platform. The experiment was terminated with 100 μL of stop solution added to each buffer and OD values at 450 nm were obtained.

2.7. Statistical analysis

Evaluation of the effects of bassiatin, tamoxifen and combined
substances on MCF-7 and SVCT cell lines was carried out by statistical studies. In addition, statistical studies have been carried out to compare MDA-MB-231 and SK-BR-3 cell lines with MCF-7 and SVCT cell lines. Kolmogorov-Smirnov test was performed to determine whether the data obtained from the studies had a normal distribution and it was determined that all the data did not show a normal distribution (P < 0.05). Therefore, for both comparisons between cell lines and comparing time and matter concentrations; the Kruskal-Wallis test was used for multiple comparisons while the Mann-Whitney U test was used for binary comparisons.

3. Results

In this study to assess the toxicity of bassiatin in MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines; 15 different concentrations of bassiatin, tamoxifen and combined substance were applied on cell lines and MTT analyses were performed after 24, 48 and 72 h of incubation. The substance-dependent inhibition in cells was visualized by fluorescence staining using a mixture of AO/PI fluorescent dyes. After 24 h of application, the effect between substances at a concentration of 75 μM is visible (Fig. 2).

Comparisons of inhibition with most effective concentrations (75, 37.5 and 25 μM) of different substances after 24 h incubation were also evaluated on MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines using bar graphs (Fig. 3). A comparison of the inhibition of 37.5 μM bassiatin, tamoxifen and combined substance between the MCF-7 breast cancer cell line and the SVCT normal breast epithelial cell line was also shown by hourly with box-plot graphs (Fig. 4).

All concentrations of bassiatin, tamoxifen and combined substance on both MCF-7 and SVCT cells were compared with each other using the Kruskal-Wallis test after 24, 48 and 72 h of incubation. A significant difference was found in all comparisons for MCF-7 (P < 0.05). In the comparison for SVCT, a significant difference was found between concentrations of tamoxifen and combined substance in the 24, 48 and 72 h incubations (P < 0.05) while there was no difference between the concentrations of bassiatin (P > 0.05).

Four cell lines (MCF-7, MDA-MD-231, SK-BR-3 and SVCT) were compared in the direction of the data obtained as a result of cytotoxicity studies with bassiatin, tamoxifen and combined substance on cell lines (Mann-Whitney U, P < 0.05). This comparison was performed separately for each concentration and incubation.

![Fig. 2. Microscopic images of dyed cell lines after 24 h treatment with 50:50 rated Acridine Orange/Propidium Iodide (AO/PI) fluorescent dye mixture obtained from cytotoxicity studies. Inhibition of MCF-7 cell line with 75 μM bassiatin (A), tamoxifen (C) and combined substance (E) and SVCT cell line with 75 μM bassiatin (B), tamoxifen (D) and combined substance (F) were shown individually. Untreated MCF-7 (G) and SVCT (H) cells are also shown. Images which are contained cells treated with a high concentration of substances have apoptotic cells with red colour. Arrows show apoptotic cells giving a red fluorescent. All Figure scales are 200 µm.](https://example.com/image2)

![Fig. 3. Effects of 75, 37.5 and 25 μM concentrations of bassiatin (A), tamoxifen (B) and combined substance (C) on MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines after 24 h treatment. Data were obtained at the result of MTT analyses with 570 nm absorbance value of reading.](https://example.com/image3)
period. In the results from the cytotoxicity studies performed with the cell lines, the concentration of the bassiatin providing a significant difference and the required dose for the treating patients was determined to be 37.5 μM (0.75 mg/mL) with EC50.

Among breast cancer cell lines, MCF-7 was selected to determine receptor-based inhibition of bassiatin at the cell cycle analyses and ELISA studies. MCF-7 and SVCT cell lines were incubated with 37.5 μM bassiatin, tamoxifen and combined substance for 24 and 48 h, and cell cycle analyses were performed using a flow cytometry. 24 h incubation period was shown by the bar graph. Bivariate histograms were obtained by evaluating cell cycle distribution in terms of G0/G1, Synthesis and G2/M ratios (Fig. 5). The data obtained by investigating the effects of bassiatin on ER, EGFR and VEGFR with commercial ELISA kits were evaluated by the generated graphs. For ERα detection, optical density values at 450 nm were used based on the amount of extract in each well and bar graphs were obtained. For EGFR and VEGFR detection, graphs were obtained based on the inhibition of receptors using optical densities at 450 nm (Fig. 6). The quantitative measurement of the amounts of the ER, EGFR and VEGFR in the samples were done by using standard curves which are obtained from OD values of the

standard of each receptor (Table 2).

4. Discussion

In this study, bassiatin, a newly discovered fungal product, was evaluated in terms of possible anti-tumour activity on breast cancer cell lines. Microscopic images obtained from cytotoxicity studies which are performed on breast cancer cell lines (MCF-7, MDA-MB-231 and SK-BR-3) and normal breast epithelial cell line (SVCT) show that bassiatin and tamoxifen are effective on the MCF-7 breast cancer cell line at high concentrations in both individually and in combination. The substances were tested up to 75 μM as the highest concentration starting from 0.25 μM and it was shown that all substances (bassiatin, tamoxifen and combined substance) have a toxic effect on MCF-7 up to a certain density compared to control (Fig. 2). This is a normal result for tamoxifen, which is currently used as an inhibitor of the oestrogen receptor in breast cancer treatment. Tamoxifen and bassiatin were compared for the first time with this study. According to this; it has been shown that both substances have a cytotoxic effect in close proportions when used individually. However, the combined substance was statistically found to have a higher toxic effect on the MCF-7 cell line compared with the individual use of substances (Kruskal-Wallis test, \( P < 0.05 \)). Since apoptotic cells show red fluorescence in the images, the effect on MCF-7 is seen more clearly (Fig. 2). This situation is compatible with today's cancer treatment methods. Because today, when some drugs are treated in combination to the cancer patients, the treatment process is shorter and the positive results are obtained sooner than the individual drugs are treated (Sayek, 1996). In the study of Pegram et al. (2004), it has been shown that trastuzumab and carboplatin, 4-hydroxycyclophosphamide, docetaxol, or vinorelbine show consistent synergistic interactions at clinically significant concentrations in HER-2 overexpressing breast cancer cells and these combinations can be tested in human clinical trials.

When the cytotoxic effect of the substances on the SVCT cell line was examined by microscopic images, it was found that bassiatin has the least toxic effect on SVCT (Fig. 2). It was observed that bassiatin did not show toxic effects in almost all concentrations compared to the control group. Even at low concentrations, tamoxifen was found to be more toxic on SVCT cell line than bassiatin and the combined substance. Red fluorescence in SVCT cells also show the apoptotic effect of tamoxifen (Fig. 2). In normal breast epithelial cells, the toxic effect of tamoxifen which is used in the treatment of breast cancer cannot be considered as a target-oriented substance in treatment and even if it is used in breast cancer treatment, it may cause many disorders in patients. This study indicates that bassiatin may be considered as a potential new breast cancer agent because of its high toxicity on MCF-7 and its minimal toxic effect on normal breast epithelium. In a study conducted by Meng et al. (2011), bassiatin was found to be effective on the MCF-7 cell line, but these scientists did not experiment with tamoxifen comparatively. In our study, we found for the first time that bassiatin is a more appropriate agent than tamoxifen. The appropriateness of the combined use of both substances was also presented for the first time with this study.

When the concentrations of the substances on the MCF-7, MDA-MB-231, SK-BR-3 and SVCT cell lines were compared with the bar graphs at 24 h incubation period, it has been shown that all substances are active and may inhibit cell proliferation at certain doses compared to control on the MCF-7 cell line (Fig. 3). It was statistically determined that the most effective substance in almost all doses is the combined substance on the MCF-7 cell line (Mann-Whitney U test, \( P < 0.05 \)). When the effect of bassiatin on cell lines is evaluated, it is seen that the most toxic effect is shown on MCF-7 in all incubation periods. However, each cell line appears to inhibit proliferation in other breast cancer cell lines when compared to the control group. When the effects of tamoxifen on different cell lines were compared, it was found to be most toxic in SVCT cell line compared to cancer cell lines (Mann-Whitney U test, \( P < 0.05 \)). In addition, both the MDA-MB-231 and SK-BR-3 cell lines showed a toxic effect on the MCF-7 cell line. This suggests that tamoxifen, which is used as an inhibitor of oestrogen receptor activity in hormone therapy, may affect different foci except ER. Scandlyn et al. (2008) also showed a new role of tamoxifen in ER-negative MDA-MB-231 cell line when it is combined with epigallocatechin gallate. Both the bassiatin and the combined substance in the SK-BR-3 breast cancer cell line, which do not carry the oestrogen receptor, were found to have a toxic effect. This suggests that we can evaluate bassiatin as an agent that targets different foci except the oestrogen receptor. In the triple-negative MDA-MB-231 cell line, a low toxic effect compared to other cell lines suggests that bassiatin has a receptor blocking feature. In the SVCT cell line, it was found that bassiatin has no toxic effect other than the slight inhibition that it showed in the 24 h incubation while tamoxifen exhibited severe toxic effect especially after 48 h of incubation (Fig. 3). When the statistical results are evaluated; there was no significant difference between the toxic effects of the substances in the low doses (\( P > 0.05 \)), although there was a significant difference in the high doses between the substances during three incubation periods on the MCF-7 cell line (\( P < 0.05 \)). On SVCT, the difference between the substances was found to be significant, except for some low doses in the 24 h incubation (\( P < 0.05 \)). It can be seen from Fig. 2 that this condition is caused by the high toxicity of tamoxifen on normal breast epithelium cells.

Comparisons of MCF-7 and SVCT cell lines in terms of concentrations of the substances are shown in graphs. The toxic effect of bassiatin on MCF-7 appears to be greater in all three incubation periods compared with the SVCT cell line. The toxic effect of tamoxifen increased in both cell lines when the dose of tamoxifen increased. However, it has been found that tamoxifen has more toxicity on SVCT cell line compared with MCF-7. Although the combined substance was found to be toxic in both cell lines, its activity was found to be much higher in the MCF-7 cell line than in SVCT (Fig. 4).

The cell cycle consists of the resting phase G0, G1, S, G2 and the mitotic M phases. There are checkpoints in the cell cycle. The situation of cell size and DNA damage are assessed at the G1/S; genotoxic stress is assessed at the G2/M and some other mistakes before division are assessed at M checkpoints. If any damage is detected at these checkpoints, the cell cycle stops. However, if there is no any abnormality in the cell cycle, the cell continues to divide. In cancer cells, these checkpoints are disabled and therefore continuous division is observed. The substances to be used in cancer treatment are expected to activate these checkpoints and prevent cell proliferation. In the evaluation of cell cycle analyses, the data obtained using flow cytometry device are shown with histograms. When the 24-h tamoxifen, bassiatin and combined substance incubations in MCF-7 cells compared with the control, it was shown that there is a reduction in the G0/G1 phase because of these substances especially bassiatin while these substances except combined substance increased S phase of MCF-7 cell cycle. It is also seen that all substances cause a reduction in the G2/M phase as shown in the G0/G1 phase (Fig. 5). Compared to the 48-h incubation period with the control, tamoxifen was found to have reduction effect in the G0/G1 phase while all the substances contributed to the reduction in the S phase. In contrast, tamoxifen, bassiatin and combined substance
increased G2/M phase and provided in cell cycle progression in 48 h incubation period of MCF-7. When the 24 and 48 h tamoxifen, bassiatin and combined substance incubations in SVCT cells compared with the control, tamoxifen induces the reduction in G0/G1 phase while tamoxifen and bassiatin promote cells separately to S phase and cause S phase increase. It was also found that the combined substance leads to increase in the G2/M phase (Fig. 3).

It has been found that tamoxifen, bassiatin and combined substance incubation for both 24 and 48 h in MCF-7 and SVCT cells have little effect on the cell cycle characteristics of the cells. The finding that bassiatin causes reduction at 24 h incubation and tamoxifen causes reduction at 48 h incubation in the G0/G1 phase of the MCF-7 cell line is consistent with the results obtained in cytotoxicity studies. Despite that; tamoxifen, bassiatin, and combined incubation have been shown to induce an increase at S phase in both cell lines, thus proliferating cells are active in cell cycle progression. Meng et al. (2011) found that bassiatin induces MCF-7 cell cycle arrest at the G0/G1 phase in the presence of oestrogen in time-dependent incubation. However, this effect is reported to be very low in the absence of oestrogen. The results obtained using bassiatin in our cell cycle analysis without oestrogen are consistent with this study. Furthermore, the effect of bassiatin on the MCF-7 cell cycle suggests that bassiatin may be considered as a possible breast cancer agent, as it currently has similar results with tamoxifen, which is actively used in breast cancer therapy.

Quantitative measurements of ER, EGFR and VEGFR with the effect of bassiatin, tamoxifen and combined substance used in the study on MCF-7 and SVCT cell lines were performed with commercial ELISA kits and the obtained results were evaluated with bar graphs. When the results obtained from oestrogen receptor detection studies are evaluated, all three substances were found to interact with the oestrogen receptor and contribute to cell inhibition according to the control group in the MCF-7 cell line (Table 2). The amount of unbound oestrogen receptor was rarely found especially in combined substance-treated cells indicates that this treatment contributes to receptor-dependent inhibition (Fig. 6). In breast cancer development, the activity of hormones such as oestrogen in breast cancer was discovered by the detection and effects of the oestrogen receptor on cell lines like MCF-7 (Brooks et al., 1973, Martin & Weber, 2000). It was thought that oestrogen receptor blocking agents would be a solution in the treatment of breast cancer. The action mechanism of tamoxifen was known with studies to act by binding to the oestrogen receptor, preventing oestrogen from inducing the cells and inhibiting cell proliferation (Zhang et al., 1999, Stewart & Wild, 2014). Bassiatin was also found to act by binding to the oestrogen receptor in the MCF-7 cell line (Meng et al., 2011). However, the comparison of two substances and the high effect of the combination of these substances have shown for the first time with this study. In the SVCT cell line study, it was observed that all substance incubations gave similar results to the control, whereas tamoxifen was shown to be the least likely to bind the oestrogen receptor as the result of the incubation (Fig. 6).

The studies for EGFR detection gave similar results with ERα studies (Table 2). This demonstrates that the combined substance may inhibit the proliferation and growth of the cancerous cell by inhibiting receptors induced by the epithelial growth factor as well as the oestrogen receptor (Fig. 6). It is known that the epithelial growth factor induces the growth and proliferation of cancerous cells and the rapid progression of cancer like oestrogen (Fan et al., 2007, Karaca Güzel, 2005). The demonstration of the inhibition effect of bassiatin at both receptors strengthens bassiatin to be considered as a possible breast cancer agent.

In VEGFR detection studies, the amount of receptors in all comparisons, including control, was low. This can be explained by the presence of this receptor in both cell lines, normally in small amounts (Table 2). Nevertheless, comparative results have shown similar results to other receptor studies, suggesting that the combined substance causes inhibition of the receptors induced by the vascular endothelial growth factor (Fig. 6). This suggests that it contributes to the inhibition of an important step such as vascularization in tumour formation. Garvin et al. (2005) were found that tamoxifen reduces at high levels the amount of unbound VEGFR with oestrogen in MCF-7 tumours with in vivo studies. In addition, it is compatible with our results that only tamoxifen treatment, even in small amounts, reduces the amount of VEGFR. As a matter of fact, there is an interpretation that cell inhibition in the presence of oestrogen may be more in the analysis of the cell cycle. The presence of oestrogen released at different levels according to hormonal balance and transmitted to specific sites of the body in women suggests that the detected effects of bassiatin, tamoxifen and combined substance may be greater in vivo compared with in vitro.

In conclusion, this study demonstrates that bassiatin which is obtained with our study is more effective than tamoxifen on the MCF-7 breast cancer cell line, this effect is achieved by receptor inhibition and the combined use of tamoxifen and bassiatin may be suitable for breast cancer treatment. This situation shows that bassiatin is as stable as tamoxifen in cell culture studies and it can be used in the long-term cancer treatment. Examining the efficacy of the substances on normal breast epithelial cells in this study was important for us to understand what kind of damage could be caused by a substance to be treated on patients in the future. The low efficacy of bassiatin on SVCT normal breast epithelial cell line compared with tamoxifen suggests that bassiatin can be regarded as a breast cancer treatment agent. The finding that high toxic effect of bassiatin on MCF-7 breast cancer cell line is based on receptor inhibition suggests that it can be used during hormone therapy, such as SERM tamoxifen. Unlike the case of Meng et al. (2011), it has been found that, since bassiatin provides EGFR and VEGFR inhibition besides ER inhibition, it cannot be regarded as only an antiestrogenic substance. Although the efficacy of bassiatin in breast cancer cell lines is expected to be characteristic of a cancer agent, it should be remembered that this study is carried out in vitro. It is necessary to look at the pharmaceutical effect by making clinical experiments and studies necessary for the next step of the study and for the commercial use of bassiatin in cancer treatment. Thus, positive results from this study and the results of pharmaceutical and in vivo drug efficacy studies will be evaluated to demonstrate the suitability of bassiatin for cancer treatment.
