(Dated: May 25, 2022)

The neutron skin thickness $\Delta r_{np}$ of heavy nuclei is essentially determined by the symmetry energy density slope $L(\rho)$ at $\rho_c = 0.11$ fm$^{-3}$, with $\rho_c$ being the nuclear saturation density, roughly corresponding to the average density of finite nuclei. The PREX collaboration recently reported a model-independent extraction of $\Delta r_{np} = 0.283 \pm 0.071$ fm for the $^{208}$Pb, suggesting a rather strong symmetry energy $E_{\text{sym}}(\rho)$ with $L(\rho_c) \geq 52$ MeV. We show that the $E_{\text{sym}}(\rho)$ cannot be too stiff and $L(\rho_c) < 73$ MeV is necessary to be compatible with (1) the ground-state properties and giant monopole resonances of finite nuclei, (2) the constraints on the equation of state of symmetric nuclear matter at suprasaturation densities from flow data in heavy-ion collisions, (3) the largest neutron star (NS) mass reported so far for PSR J0740+6620, (4) the NS tidal deformability extracted from gravitational wave signal GW170817 and (5) the mass-radius of PSR J0030+045 measured simultaneously by NICER. This allows us to obtain $52 \leq L(\rho_c) \leq 73$ MeV and $0.212 \leq \Delta r_{np} \leq 0.271$ fm, and further $E_{\text{sym}}(\rho_0) = 34.3 \pm 1.7$ MeV, $L(\rho_0) = 83.4 \pm 24.7$ MeV, and $E_{\text{sym}}(2\rho_0) = 62.8 \pm 15.9$ MeV. A number of critical implications on nuclear physics and astrophysics are discussed.

Introduction.— The Lead Radius Experiment (PREX) collaboration recently reported a model-independent extraction of $\Delta r_{np}^{208} = 0.283 \pm 0.071$ fm [1] for the neutron skin thickness (the difference between the rms radii of the neutron and proton distributions, $\Delta r_{np} \equiv r_n - r_p$) of $^{208}$Pb by combining the original PREX result [2] with the new PREX-II measurement [1]. This updated result (hereafter referred to as simply “PREX-II”) reaches a precision close to 1% for $r_n$, much more precise than the original $\Delta r_{np}^{208} = 0.334^{+0.16}_{-0.15}$ fm [2]. In PREX, the neutron density distribution in $^{208}$Pb is determined by measuring the parity-violating electroweak asymmetry in the elastic scattering of polarized electrons off $^{208}$Pb and thus is free from the strong interaction uncertainties. Since the proton is charged and its distributions are well determined, the $\Delta r_{np}^{208} = 0.283 \pm 0.071$ fm may represent the cleanest and most accurate $\Delta r_{np}$ so far although the more precise measurement has been planned at MESA [3]. The coherent elastic neutrino-nucleus scattering [4] provides another clean way to extract the $\Delta r_{np}$, but the current uncertainty is too large [5,6]. The $0.283 \pm 0.071$ fm means a rather thick $\Delta r_{np}$, significantly larger than those extracted from other approaches that suffer from the uncertainties of the strong interaction (see, e.g., Ref. [7] for a recent review).

Besides its fundamental importance for nuclear structure, the $\Delta r_{np}$ has been identified as an ideal probe on the symmetry energy $E_{\text{sym}}(\rho)$ — a key but poorly-known quantity that encodes the isospin dependence of nuclear matter equation of state (EOS) and plays a critical role in many issues in nuclear physics and astrophysics [8–13]. Indeed, it has been established [14–19] that the $\Delta r_{np}$ exhibits a strong positive linear correlation with the symmetry energy density slope $L(\rho)$ at nuclear saturation density $\rho_0 \approx 0.16$ fm$^{-3}$, i.e., $L \equiv L(\rho_0)$. An even stronger correlation is found between the $\Delta r_{np}$ of heavy nuclei and the $L(\rho)$ at a subsaturation cross density $\rho_c = 0.11$ fm$^{-3}$, roughly corresponding to the average density of finite nuclei, i.e., $L_c \equiv L(\rho_c)$. Furthermore, the $L(\rho)$ around $\rho_0$ strongly influences the mass-radius (M-R) relation and tidal deformability of neutron stars (NSs), and thus provides a unique bridge between atomic nuclei and NSs [21,23].

The large value of $\Delta r_{np}^{208} = 0.283 \pm 0.071$ fm suggests a very stiff $E_{\text{sym}}(\rho)$ (a large $L(\rho)$) around $\rho_0$, which generally leads to a very large NS radius and tidal deformability. However, an upper limit of $L_{1.4} \leq 580$ [24] for the dimensionless tidal deformability of $1.4 M_\odot$ NS has been obtained from the gravitational wave signal GW170817, which requires a relatively softer $E_{\text{sym}}(\rho)$. In addition, the heaviest NS with mass $2.14^{+0.10}_{-0.05} M_\odot$ for PSR J0740+6620 [26] also strongly limits the $E_{\text{sym}}(\rho)$ [24], especially under the constraints on the EOS of symmetric nuclear matter (SNM) at suprasaturation densities from flow data in heavy-ion collisions (HIC) [27], which is relatively soft and strongly restricts the NS maximum mass $M_{\text{max}}$ [23,24,28]. Furthermore, two independent simultaneous M-R determinations from NICER [29,30] for PSR J0030+0451 with mass around $1.4 M_\odot$ has been obtained, further constraining the $E_{\text{sym}}(\rho)$. Given the rich multimessenger data, it is extremely important to develop a unified framework that can simultaneously describe the finite nuclei and NSs which involve a very large density range. Actually, serious tension between $\Delta r_{np}^{208} = 0.283 \pm 0.071$ fm and the limits from GW170817 and NICER has been observed in a covariant density...
functional study \cite{31}.

In this work, within a single unified framework of the extended Skyrme-Hartree-Fock (eSHF) model \cite{32,33} which includes momentum dependence of effective many-body forces, we find the $L_c$ cannot be larger than 73 MeV under the constraints from GW170817, NICER, the NS mass $2.14^{+0.10}_{-0.09} M_{\odot}$, flow data in heavy-ion collisions, and the data of ground-state properties and giant monopole resonances (GMR) of finite nuclei. Our findings produce an upper limit of $\Delta_{\text{np}}^{208} \leq 0.271$ fm, and this together with the $\Delta_{\text{np}}^{208} = 0.283 \pm 0.071$ fm lead to stringent constraints of $0.212 \leq \Delta_{\text{np}}^{208} \leq 0.271$ fm and correspondingly 52 \leq L_c \leq 73$ MeV, which have a number of critical implications in nuclear physics and astrophysics.

Model and method.— The EOS of nuclear matter at density $\rho = \rho_n + \rho_p$ and isospin asymmetry $\delta = (\rho_n - \rho_p)/\rho$ with $\rho_n(\rho_p)$ denoting the neutron(proton) density, defined by the binding energy per nucleon, can be expressed as

$$E(\rho, \delta) = E_0(\rho) + E_{\text{sym}}(\rho)\delta^2 + O(\delta^4), \quad (1)$$

where $E_0(\rho) = E(\rho, \delta = 0)$ is SNM EOS and $E_{\text{sym}}(\rho) = \frac{1}{2!} \frac{\partial^2 E(\rho, \delta)}{\partial \delta^2} \bigg|_{\delta = 0}$ is the symmetry energy. At $\rho_0$, the $E_0(\rho)$ can be expanded in $\chi = (\rho - \rho_0)/(3\rho_0)$ as $E_0(\rho_0) + \frac{1}{2!} \frac{\partial E(\rho_0)}{\partial \rho} \rho + \frac{1}{2} \frac{\partial E(\rho_0)}{\partial \chi} \chi + 0(\chi^2)$, in terms of incompressibility $K_0$ and skewness $J_0$. The $E_{\text{sym}}(\rho)$ can be expanded at a reference density $\rho_0$ in terms of the slope parameter $L(\rho_0)$ and the curvature parameter $K_{\text{sym}}(\rho_0)$ as $E_{\text{sym}}(\rho) = E_{\text{sym}}(\rho_0) + L(\rho_0)\chi + \frac{1}{2} K_{\text{sym}}(\rho_0)\chi^2 + 0(\chi^3)$, with $\chi_0 = (\rho - \rho_0)/(3\rho_0)$. Setting $\rho_0 = \rho_0$ leads to the conventional $L \equiv L(\rho_0)$ and $K_{\text{sym}} \equiv K_{\text{sym}}(\rho_0)$.

Within the eSHF model \cite{32,33} which includes 13 Skyrme interaction parameters $\alpha, t_0 \sim t_5, x_0 \sim x_5$ and the spin-orbit coupling constant $W_0$, we have

$$E_0(\rho) = \frac{3\rho^2}{10m} k_F^2 + \frac{3}{8} t_0 \rho + \frac{3}{80} \left[t_1 + t_2(4x_2 + 5)\right] \rho k_F^2 + \frac{1}{16} t_0 \rho^2 \Delta_1 + \frac{3}{80} \left[t_4 + t_5(4x_5 + 5)\right] \rho^2 k_F^2, \quad (2)$$

and

$$E_{\text{sym}}(\rho) = \frac{\hbar^2}{6m} k_F^2 - \frac{1}{8} t_0 (2x_0 + 1) \rho - \frac{1}{48} t_3 (2x_3 + 1) \rho^{\Delta_1 + 1} - \frac{1}{24} \left[t_{11} x_1 + t_2 (4 + 5x_2)\right] \rho k_F^2 - \frac{1}{24} \left[t_{12} x_2 + t_3 (4 + 5x_3)\right] \rho^2 k_F^2, \quad (3)$$

where $m$ is the nucleon rest mass and $k_F = (3\pi^2/2\rho)^{1/3}$ is the Fermi momentum. The last term in Eqs. \cite{2} and \cite{3} is from the momentum dependence of three-body forces which are not considered in the standard SHF model (see, e.g., Ref. \cite{23}). The eSHF provides a successful framework to describe simultaneously nuclear matter, finite nuclei, and NSs \cite{33}. The 13 Skyrme parameters $\alpha, t_0 \sim t_5, x_0 \sim x_5$ can be expressed explicitly in terms of the following 13 macroscopic quantities (pseudo-parameters) \cite{33}: $\rho_0$, $E_0(\rho_0)$, $K_0$, $J_0$, $E_{\text{sym}}(\rho_0)$, $L(\rho_0)$, $K_{\text{sym}}(\rho_0)$, the isoscalar effective mass $m_{\text{s,0}}$, the isovector effective mass $m_{\text{v,0}}$, the gradient coefficient $G_S$, and the symmetry-gradient coefficient $G_V$, the cross gradient coefficient $G_{SV}$, and the Landau parameter $G_0$ of SNM in the spin-isospin channel. Instead of directly using the 13 Skyrme parameters, we use here the 13 macroscopic model parameters in the eSHF calculations for nuclear matter, finite nuclei and NSs \cite{33}.

For NSs, we consider the conventional NS model, i.e., the NS contains core, inner crust and outer crust with the core including only neutrons, protons, electrons and possible muons ($npe\mu$). For the details, one is referred to Refs. \cite{23,24,33}. We would like to emphasize that in the following NS calculations, the core EOS is obtained from full eSHF calculations with model parameters constrained by properties of both finite nuclei and NSs as well as HIC flow data, and the core-crust transition density $\rho_c$ is determined self-consistently by a dynamical approach \cite{24}. In addition, all the constructed eSHF parameter sets used in the following NS calculations are required to satisfy the causality condition.

Result and discussion.— For the 13 macroscopic model parameters in eSHF, we fix $E_{\text{sym}}(\rho_c) = 26.65$ MeV since it has been obtained with high precision by analyzing the binding energy difference of heavy isotope pairs \cite{20}. Furthermore, the $L_c$ essentially determines the $\Delta_{\text{np}}^{208}$ of heavy nuclei \cite{20}, while the higher-order parameters $J_0$ and $K_{\text{sym}}$ only weakly affect the properties of finite nuclei but are critical for NS properties \cite{23,24}. To explore the $\Delta_{\text{np}}^{208}$ and NSs, therefore, our strategy is to search for the parameter space of $L_c$, $J_0$ and $K_{\text{sym}}$ under the constraints on the SNM EOS from flow data as well as the limits from GW170817 and NS observations, while with the other 10 parameters ($\rho_0$, $E_0(\rho_0)$, $K_0$, $m_{\text{s,0}}$, $m_{\text{v,0}}$, $G_S$, $G_V$, $G_{SV}$, $G_0$, and $W_0$) being obtained by fitting the nuclear data on the binding energies, charge rms radii, GMR energies, and spin-orbit energy level splittings (see Refs. \cite{23,24,33} for details) to guarantee that the eSHF can successfully describe nuclear properties (the relative deviations of charge radii and total binding energies for medium and heavy nuclei from data are less than 0.5%). From the obtained $L_c$, $J_0$ and $K_{\text{sym}}$, one can extract information on EOS, $\Delta_{\text{np}}^{208}$, and NSs.

A larger $L_c$ generally leads to a larger $\Delta_{\text{np}}^{208}$ and correspondingly a larger $A_{1,4}$. For fixed $L_c$ and $J_0$, reducing the $K_{\text{sym}}$ can effectively reduce the $A_{1,4}$ but also reduces the NS maximum mass $M_{\text{max}}$ \cite{23,24}. Furthermore, increasing $J_0$ can enhance significantly the $M_{\text{max}}$ but the $J_0$ cannot be too large \cite{23,24,28} due to relatively soft SNM EOS constrained by the flow data. Using the limit of $A_{1,4} \leq 580$ from GW170817, $M_{\text{max}} \geq 2.05 M_{\odot}$ from PSR J0740+6620, and the flow data constraint on SNM EOS, one thus expects there should exist an upper limit for $L_c$ (also for $J_0$ and $K_{\text{sym}}$). Figs. \cite{1}(a), (b), and (c)
show the $M_{\text{max}}$ vs $K_{\text{sym}}$ at various $J_0$ with $L_c = 57, 65$, and 73 MeV, respectively. The shadowed regions represent the allowed parameter space of $J_0$ and $K_{\text{sym}}$, which all satisfy the limits of $\Delta_{1,4} \leq 580$, $M_{\text{max}} \geq 2.05 M_0$, and the flow data constraint. We note that the allowed parameter space agrees with $\Delta r_{np}^{208} \geq 0.212$ fm. As expected, one sees from Fig. 1 that the allowed parameter space becomes smaller and smaller with increasing $L_c$ (see also Ref. 24), and it is essentially reduced to a point at $L_c = 73$ MeV with $K_{\text{sym}} = -82$ MeV and $J_0 = -353$ MeV as shown in Fig. 1(c) (the corresponding parameter set is denoted as ‘Lc73’). Therefore, our results indicate the $L_c$ has an upper limit of $L_c \leq 73$ MeV.

We note that the eSHF with Lc73 predicts $E_{\text{sym}}(\rho_c) \approx E_{\text{sym}}(\rho_0) + L\chi + \frac{1}{2}K_{\text{sym}}\chi^2$, which is a very good approximation to $E_{\text{sym}}(\rho)$ for density less than about $2\rho_0$ 33 37. Taking $\rho_c = 0.11$ fm$^{-3}$ $\approx 2/3\rho_0$, one can obtain the following relations

$$L \approx 3L_c/2 + K_{\text{sym}}/9,$$

$$E_{\text{sym}}(\rho_0) \approx E_{\text{sym}}(\rho_c) + L_c/6 + K_{\text{sym}}/162,$$

$$E_{\text{sym}}(2\rho_0) \approx E_{\text{sym}}(\rho_c) + 2L_c/3 + 8K_{\text{sym}}/81,$$

which indicate the $L$, $E_{\text{sym}}(\rho_0)$ and $E_{\text{sym}}(2\rho_0)$ are all linearly correlated with $L_c$ (and thus $\Delta r_{np}^{208}$) for fixed $E_{\text{sym}}(\rho_c)$ and small disturbance from $K_{\text{sym}}$. From the strong linear correlations shown in Fig. 2 one obtains $L = 83.1 \pm 24.7$ MeV, $E_{\text{sym}}(\rho_0) = 34.3 \pm 1.7$ MeV, and $E_{\text{sym}}(2\rho_0) = 62.8 \pm 15.9$ MeV. These results suggest a rather stiff symmetry energy around $\rho_0$, in contrast to the constraints $E_{\text{sym}}(\rho_0) = 31.6 \pm 2.7$ MeV and $L = 58.9 \pm 16$ MeV 38 39, or $E_{\text{sym}}(\rho_0) = 31.7 \pm 3.2$ MeV and $L = 58.7 \pm 28.1$ MeV 40, and $E_{\text{sym}}(2\rho_0) = 47.2^{+21.1}_{-22.5}$ MeV 41, obtained by averaging essentially all the existing constraints. In addition, ab initio coupled-cluster calculations 42 predict a rather soft symmetry energy of $37.8 \leq L \leq 47.7$ MeV and $25.2 \leq E_{\text{sym}}(\rho_0) \leq 30.4$ MeV, which are significantly smaller than our present constraints. It is interesting to mention that the present constraints are in surprisingly good agreement with the
earlier constraint \( L = 88 \pm 22 \text{ MeV} \) obtained from transport model analyses \cite{13} on the isospin diffusion data \cite{44} in heavy-ion collisions, as well as the constraints \( E_{\text{sym}}(\rho_t) = 35.0 \pm 1.5 \text{ MeV} \) and \( L = 85.5 \pm 15.5 \text{ MeV} \) obtained from the analyses of isovector skin and isobaric analog states \cite{46}.

Figure 3 shows the correlation of \( \Delta r_{np}^{208} \) with the crust-core transition density \( \rho_t \), the threshold density \( \rho_{DU} \) and threshold NS mass \( M_{DU} \) above which the direct Urca (DU) process \((n \rightarrow p + e^- + \bar{\nu}_e, p + e^- \rightarrow n + \nu_e)\) \cite{47} becomes possible, the radius \( R_M \) of NS with mass \( M = 1.0M_\odot, 1.4M_\odot \) and \( 1.6M_\odot \) as well as \( M = 1.34M_\odot \) and \( 1.44M_\odot \). One sees the \( \Delta r_{np}^{208} \) exhibits a strong linear (anti-)correlation with all these NS properties, which together with the constraint \( 0.212 \text{ fm} \leq \Delta r_{np}^{208} \leq 0.271 \text{ fm} \) allow us to obtain following information: \( \rho_t = 0.065 \pm 0.010 \text{ fm}^{-3}, \rho_{DU} = 0.313 \pm 0.096 \text{ fm}^{-3}, \)
\( M_{DU} = (1.09 \pm 0.41)M_\odot, R_{1.0} = 14.07 \pm 0.91 \text{ km}, R_{1.4} = 13.66 \pm 0.71 \text{ km}, R_{1.6} = 13.44 \pm 0.68 \text{ km}, R_{1.34} = 13.72 \pm 0.72 \text{ km}, \) and \( R_{1.44} = 13.62 \pm 0.70 \text{ km} \). Our results suggest a relatively small \( \rho_t \), implying the NS crust will have a small thickness, fractional mass, and moment of inertia \cite{35}. The \( M_{DU} \) will clearly occur in NSs with mass larger than \( 1.50M_\odot \) (central density larger than \( 0.409 \text{ fm}^{-3} \)). Furthermore, if \( \Delta r_{np}^{208} \) were larger than \( 0.25 \text{ fm} \), one obtains \( M_{np} < 1.0M_\odot \), and this means the DU process will occur in essentially all the observed NSs. The DU process will enhance the emission of neutrinos and make it a more important process in the cooling of a NS \cite{47}. This observation is particularly interesting given the fact that a fast neutrino-cooling process has been suggested by the detected x-ray spectrum of the NS in the low-mass x-ray binary MXB 1659-29 \cite{48}. Nevertheless, it should be mentioned that the NS cooling can be significantly influenced by nucleon pairing \cite{49,50}.

As for the NS radii, very strong limits with a precision of \( 5\% \) have been obtained. In particular, our present results \( R_{1.34} = 13.72 \pm 0.72 \text{ km} \) and \( R_{1.44} = 13.62 \pm 0.70 \text{ km} \) are in agreement with the NICER constraints \cite{49,50} but have much better precision. It is interesting to point out that the NICER constraints have not been imposed in constructing the parameter sets of \( L_c = 30 \sim 90 \text{ MeV} \), implying in eSHF, they are compatible with \( \Lambda_{1.4} \leq 580 \) and \( M_{\text{max}} \geq 2.05M_\odot \) as well as the flow data constraints on SNM EOS. It should be noted that the NS radius depends on the poorly-known inner crust EOS \cite{35,51} but \( \Lambda_{1.4} \) does not \cite{52}, and thus it is relatively safer to use \( \Lambda_{1.4} \) as a constraint.

Shown in Fig. 1 is the \( \Delta r_{np}^{208} \) vs the \( \Delta r_{np} \) of \( ^{48}\text{Ca} \), \( ^{96}\text{Zr}, ^{96}\text{Ru}, ^{127}\text{I}, ^{133}\text{Cs}, ^{132}\text{Xe} \) and very strong positive linear correlations are seen between the \( \Delta r_{np} \) of these nuclei. Using \( 0.212 \text{ fm} \leq \Delta r_{np}^{208} \leq 0.271 \text{ fm} \) together with the linear correlations, we obtain \( \Delta r_{np}^{48}(\text{Ca}) = 0.202 \pm 0.020 \text{ fm} \) for \( ^{48}\text{Ca}, \Delta r_{np}^{96}(\text{Zr}) = 0.216 \pm 0.025 \text{ fm} \) for \( ^{96}\text{Zr}, \Delta r_{np}^{96}(\text{Ru}) = 0.059 \pm 0.012 \text{ fm} \) for \( ^{96}\text{Ru}, \Delta r_{np}^{127}(\text{I}) = 0.184 \pm 0.025 \text{ fm} \) for \( ^{127}\text{I}, \Delta r_{np}^{133}(\text{Cs}) = 0.187 \pm 0.025 \text{ fm} \) for \( ^{133}\text{Cs}, \) and \( \Delta r_{np}^{132}(\text{Xe}) = 0.204 \pm 0.027 \text{ fm} \) for \( ^{132}\text{Xe} \).

Particularly interesting is the \( \Delta r_{np}^{48}(\text{Ca}) \) as it has been predicted to be \( 0.12 \leq \Delta r_{np}^{48}(\text{Ca}) \leq 0.15 \text{ fm} \) from \textit{ab initio} coupled-cluster calculations \cite{42}, which is significantly smaller than our result \( \Delta r_{np}^{48}(\text{Ca}) = 0.202 \pm 0.020 \text{ fm} \). At this point, we must mention that the Calcium Radius EXPERiment (CREX) \cite{1} is expected to finish the data analysis on \( \Delta r_{np}^{48}(\text{Ca}) \) soon with a precision of \( 0.5\% \) (or \( \pm 0.02 \text{ fm} \)) for its \( r_{np} \). CREX can thus provide a unique bridge between \textit{ab initio} approaches and density functional theory (DFT). This is particularly important as the DFT (e.g., eSHF) is still the only realistic framework to investigate the physics of heavy nuclei and NSs.

The \( \Delta r_{np}^{96}(\text{Zr}) \) and \( \Delta r_{np}^{96}(\text{Ru}) \) are also very interesting since a recent study \cite{52} has demonstrated that the isobaric \( ^{96}\text{Zr}, ^{96}\text{Zr} \) and \( ^{96}\text{Ru}+^{96}\text{Ru} \) collisions at relativistic energies can be used to extract the \( \Delta r_{np} \) of \( ^{96}\text{Zr} \) and \( ^{96}\text{Ru} \) with a weak model-dependence. The \( \Delta r_{np}^{96}(\text{Zr}) \) and \( \Delta r_{np}^{96}(\text{Ru}) \) are also crucial for the chiral magnetic effect search in isobaric collisions \cite{52}. Our present results of \( \Delta r_{np}^{96}(\text{Zr}) \) and \( \Delta r_{np}^{96}(\text{Ru}) \) are particularly timely, because
the data on these isobaric collisions at RHIC have been taken in 2018 and have been subject to a blinded analysis to assess the chiral magnetic effect. In addition, our results of $\Delta r_{np}^{127}$ (I) and $\Delta r_{np}^{133}$ (Cs) are critical for the information extraction of new physics via coherent elastic neutron-nucleus scattering in the COHERENT experiment [1], while the $\Delta r_{np}^{132}$ (Xe) is important for dark matter direct detection in liquid Xe detector [54].

Finally, it is instructive to see how our results change if the adopted constraints are varied. We note the upper limit of $\Lambda_{1.4} \leq 580$ [25] is altered into $\Lambda_{1.4} \leq 720$ which seems to be favored if a NS maximum mass of $1.97 M_\odot$ is imposed in the analysis of GW170817 [55]. In addition, varying the $M_{\text{max}} \geq 2.05 M_\odot$ [26] into the recently updated $M_{\text{max}} \geq 2.01 M_\odot$ [56] from PSR J0740+6620 only changes $L_c \leq 73$ MeV to $L_c \leq 74$ MeV, enhancing the pressure upper limit of SNM EOS constraint from the flow data by 10% essentially does not change the limit $L_c \leq 73$ MeV, and replacing $E_{\text{sym}}(\rho_0) = 26.65$ MeV by $E_{\text{sym}}(\rho_0) = 25.65\,(27.65)$ MeV leads to $L_c \leq 69\,(75)$ MeV. We also note replacing $\Lambda_{1.4} \leq 580$ by $\Lambda_{1.4} \leq 720$ leads to $0.212 \leq \Delta r_{np}^{208} \leq 0.288$ fm, $E_{\text{sym}}(\rho_0) = 34.8 \pm 2.1$ MeV, $L(\rho_0) = 89.0 \pm 30.6$ MeV, and $E_{\text{sym}}(2\rho_0) = 65.7 \pm 18.7$ MeV. At last, it should be noted that the present results are based on the conventional NS model in a single unified framework without considering possible new degrees of freedom (hyperons, meson condensates, quark matter, and so on) and modified gravity.

**Conclusion.**— We have demonstrated the symmetry energy slope parameter $L_c$ cannot be larger than 73 MeV under the condition of $\Lambda_{1.4} \leq 580$, and this leads to an upper limit of $\Delta r_{np}^{208} \leq 0.271$ fm. This limit together with the recent model-independent measurement on $\Delta r_{np}^{208}$ from PREX-II leads to a rather large but very precise constraint of $0.212 \leq \Delta r_{np}^{208} \leq 0.271$ fm, which suggests a rather stiff symmetry energy around $\rho_0$ and has critical implications on many issues in nuclear physics and astrophysics. In particular, our present constraints on the symmetry energy and the neutron skin of $^{48}$Ca reveal serious tension with the predictions from ab initio coupled-cluster theory, and the soon coming data from CREX thus become extremely important.
