Abstract

We isolate a new large cardinal concept, "remarkability." It turns out that the existence of a remarkable cardinal is equiconsistent with $L(\mathbb{R})$ absoluteness under proper forcings. As remarkable cardinals are compatible with $V = L$, this means that said absoluteness does not imply $\Pi^1_1$ determinacy.

0 Introduction.

It is well-known that the existence of large cardinals implies various forms of determinacy. It is also true that the existence of large cardinals implies that the theory of $L(\mathbb{R})$ cannot be changed by set-forcing. It was an interesting observation (due to Steel and Woodin) to see that already the fact that the theory of $L(\mathbb{R})$ cannot be changed by set-forcing implies that the axiom of determinacy holds in $L(\mathbb{R})$.

Large cardinals imply more: [2] and [3] show that – under appropriate assumptions – the "boldface" theory of $L(\mathbb{R})$ cannot be changed by set-sized proper forcing. Here, "boldface" means that reals from the ground model as well as ordinals are allowed as parameters. A natural question arises: (⋆) which amount of determinacy do the conclusions of the main theorems of [2] and [3] give (back)?

This question is particularly interesting, as the forcing which Steel and Woodin use to prove their above-mentioned observation collapses $\omega_1$. The question thus really is whether the Steel-Woodin argument can be refined by using more "coding like" forcings instead. [4] gave some partial answers, albeit in a somewhat different direction. We here provide a straight answer to (⋆). In order to formulate it let us introduce some terminology.

---

Keywords: set theory/descriptive set theory/proper forcing/large cardinals.
Definition 0.1 Let $\mathcal{F} \subset V$ be a class of posets. We say that $L(\mathbb{R})$ is absolute under forcings of type $\mathcal{F}$ if for all posets $P \in \mathcal{F}$, for all $H$ being $P$-generic over $V$, for all formulae $\Phi(\vec{v})$, and for all $\vec{x} \in \mathbb{R}^V$ do we have that

$$L(\mathbb{R}^V) \models \Phi(\vec{x}) \iff L(\mathbb{R}^{V[G]}) \models \Phi(\vec{x}).$$

We say that $L(\mathbb{R})$ is absolute under proper forcings if $L(\mathbb{R})$ is absolute under forcings of type $\mathcal{F}$ where $\mathcal{F} = \{P \in V : P$ is proper $\}$.

Definition 0.2 Let $\mathcal{F} \subset V$ be a class of posets. We say that the $L(\mathbb{R})$ embedding theorem holds for forcings of type $\mathcal{F}$ if for all posets $P \in \mathcal{F}$, for all $H$ being $P$-generic over $V$, for all formulae $\Phi(\vec{v})$, for all $\vec{\alpha} \in \text{OR}$, and for all $\vec{x} \in \mathbb{R}^V$ do we have that

$$L(\mathbb{R}^V) \models \Phi(\vec{\alpha}, \vec{x}) \iff L(\mathbb{R}^{V[G]}) \models \Phi(\vec{\alpha}, \vec{x}).$$

We say that the $L(\mathbb{R})$ embedding theorem holds for proper forcings if $L(\mathbb{R})$ is absolute under forcings of type $\mathcal{F}$ where $\mathcal{F} = \{P \in V : P$ is proper $\}$.

Definition 0.3 Let $\mathcal{F} \subset V$ be a class of posets. We say that the $L(\mathbb{R})$ anti coding theorem holds for forcings of type $\mathcal{F}$ if for all posets $P \in \mathcal{F}$, for all $H$ being $P$-generic over $V$, and for all $A \subset \text{OR}$ with $A \in V$ do we have that

$$A \in L(\mathbb{R}^V) \iff A \in L(\mathbb{R}^{V[G]}).$$

We say that the $L(\mathbb{R})$ anti coding theorem holds for proper forcings if the $L(\mathbb{R})$ anti coding theorem holds for forcings of type $\mathcal{F}$ where $\mathcal{F} = \{P \in V : P$ is proper $\}$.

Our main theorem, 

will then say that $L(\mathbb{R})$ absoluteness under proper forcings is equiconsistent with the existence of what we call a ”remarkable” cardinal, and the same holds for the $L(\mathbb{R})$ embedding theorem for proper forcings, as well as the $L(\mathbb{R})$ anti coding theorem for proper forcings. As remarkable cardinals turn out to be compatible with $V = L$, this means that the answer to (**) is that the conclusions of the main theorems of [2] and [3] do not even imply $\Pi^1_1$ determinacy.

We hope that there will be other applications of remarkable cardinals in the future; anyway, ”remarkability” seems to be an interesting concept.
1 Preliminaries.

Lemma 1.1 Let $\mathcal{M} = (M; (R_i; i < n))$ and $\mathcal{N} = (N; (S_i; i < m))$ be models such that $n \leq m$, $R_i$ has the same arity as $S_i$ for $i < n$, and $M$ is countable. Then there is a tree $T$ of height $\leq \omega$ searching for $(R_i; n \leq i < m)$ together with an elementary embedding

$$\pi: (M; (R_i; i < m)) \rightarrow (N; (S_i; i < m)).$$

Proof. Let $(e_i; i < \omega)$ be an enumeration of $M$, and let $(\Phi_i(\vec{v}); i < \omega)$ be an enumeration of all formulae of the language associated with $N$. Let $\#(i)$ denote the arity of $R_i$ (= of $S_i$) for $i < n$. Let $\gamma: \omega \rightarrow \omega \times <\omega\omega$ be such that $\Phi_{\#(i)}$ has the variables with indices $< dom(\gamma(i))$ as its free variables and $ran(\gamma(i)) \subset i - 1$, and such that $\gamma$ is "onto" in the obvious sense. Let $F$ be a Skolem function for $N$; more precisely, let $F(i, \vec{x})$ be such that

$$\mathcal{N} \models \exists y \Phi_i(y, \vec{x}) \Rightarrow \Phi_i(F(i, \vec{x}), \vec{x})$$

(if there is no such $y$ then we let $F(i, \vec{x})$ undefined). Let the $k^{th}$ level of $T$ consist of sequences $f: k \rightarrow N$ such that $f \upharpoonright k - 1 \in (k - 1)^{st}$ level of $T$,

$$\forall i < n \forall \{l_1, ..., l_{\#(i)}\} \subset k \ (R_i(e_{l_1}, ..., e_{l_{\#(i)}}) \Leftrightarrow S_i(f(l_1), ..., f(l_{\#(i)}))), \ \text{and}$$

$$f(k - 1) = F(\gamma(k)0, f \circ \gamma(k)1(1), ..., f \circ \gamma(k)0, \gamma(k)1(dom(\gamma(k))))(1) - 1))$$

(if this is defined, otherwise we let $f(k - 1) = \text{an arbitrary element of } N$).

Now if $f: \omega \rightarrow N$ is given by an infinite branch through $T$ then it is easy to see that setting $R_i(e_{l_1}, ..., e_{l_{\#(i)}}) \Leftrightarrow S_i(f(l_1), ..., f(l_{\#(i)}))$ for $n \leq i < m$ and $\pi(e_i) = f(i)$ we get relations and an embedding as desired. On the other hand, any such relations together with some such embedding defines an infinite branch through $T$.

$\square$ (1.1)

As an immediate corollary to this proof we get the following.

Lemma 1.2 Let $\mathcal{M} = (M; (R_i; i < n))$ and $\mathcal{N} = (N; (S_i; i < m))$ be models such that $n \leq m$, $R_i$ has the same arity as $S_i$ for $i < n$, and $M$ is countable. Let $Q$ be an admissible set such that $\mathcal{M}, \mathcal{N} \in Q$, and $M$ is countable in $Q$. If in $V$ there are $R_i, n \leq i < m$, together with an elementary embedding

$$\pi: (M; (R_i; i < m)) \rightarrow (N; (S_i; i < m))$$

then such $R_i, \pi$ also exist in $Q$. 

3
2 Remarkable cardinals.

Definition 2.1 A cardinal $\kappa$ is called remarkable iff for all regular cardinals $\theta > \kappa$ there is some $\pi: M \rightarrow H_\theta$ with $M$ being countable and transitive and $\kappa \in \text{ran}(\pi)$ and such that, setting $\bar{\kappa} = \pi^{-1}(\kappa)$, there is some $\sigma: M \rightarrow N$ with critical point $\bar{\kappa}$ and such that $N$ is countable and transitive, $\bar{\theta} = M \cap OR$ is a regular cardinal in $N$, $M = H^N_{\bar{\theta}}$, and $\sigma(\bar{\kappa}) > \bar{\theta}$.

As a matter of fact, "remarkability" relativizes down to $L$, i.e., any remarkable cardinal is also remarkable in $L$ (cf. 2.3 below). Hence the existence of remarkable cardinals is consistent with $V = L$. One can also show that every remarkable cardinal is totally indescribable. In particular, the least measurable cardinal is not remarkable. However, every strong cardinal is remarkable, and we shall see below (cf. 2.3) that every Silver indiscernible is remarkable in $L$.

The following two lemmata will give information as to where remarkable cardinals sit in the large cardinal hierarchy.

Lemma 2.2 Let $\kappa \rightarrow (\omega)^{<\omega}$. Then there are $\alpha < \beta < \omega_1$ such that $L_\beta \models "\text{ZFC} + \alpha \text{ is a remarkable cardinal."}"

Proof. We may assume that $V = L$, as $\kappa \rightarrow (\omega)^{<\omega}$ relativizes down to $L$. Let $\pi: L_\gamma \rightarrow L_\kappa$ be such that $\text{ran}(\pi)$ is the Skolem hull in $L_\kappa$ of $\omega$ many indiscernibles for $L_\kappa$. Let $\alpha$, $\beta$ (with $\alpha < \beta$) be the images of the first two indiscernibles under $\pi^{-1}$. Of course, $L_\beta \models \text{ZFC}$, as any of the indiscernibles in inaccessible in $L$. We claim that $\alpha$ is remarkable in $L_\beta$.

Let $\theta < \beta$ be regular in $L_\beta$ with $\theta > \alpha$. There is $\sigma: L_\gamma \rightarrow L_\gamma$ with $\sigma(\alpha) = \beta$, obtained from shifting the indiscernibles. I.e., there is some countable $L_{\bar{\theta}}$ (namely, $L_{\theta}$) together with some $\bar{\pi}: L_{\bar{\theta}} \rightarrow L_{\pi(\theta)}$ (namely, $\pi\upharpoonright L_{\theta}$) such that $\pi(\alpha)$ is in the range of $\bar{\pi}$ and there is some $\sigma: L_{\bar{\theta}} \rightarrow L_{\bar{\theta}}$ (namely, $\sigma\upharpoonright L_{\theta}$) with critical point $\bar{\pi}^{-1}(\pi(\alpha))$ such that $\bar{\sigma}$ is countable, $\bar{\theta}$ is a regular cardinal in $L_{\bar{\theta}}$, and $\bar{\sigma}(\bar{\pi}^{-1}(\pi(\alpha))) > \bar{\theta}$. As $\pi(\beta)$ is inaccessible in $L$, the same holds in $L_{\pi(\beta)}$. Pulling it back via $\bar{\pi}^{-1}$ we get that in $L_\beta$ there is some countable $L_{\bar{\theta}}$ together with some $\bar{\pi}: L_{\bar{\theta}} \rightarrow L_{\theta}$ such that $\alpha$ is in the range of $\bar{\pi}$ and there is some $\bar{\sigma}: L_{\bar{\theta}} \rightarrow L_{\bar{\theta}}$ with critical point $\bar{\pi}^{-1}(\pi(\alpha))$ such that $\bar{\theta}$ is countable, $\bar{\theta}$ is a regular cardinal in $L_{\bar{\theta}}$, and $\bar{\sigma}(\bar{\pi}^{-1}(\pi(\alpha))) > \bar{\theta}$. As $\theta > \alpha$ was an arbitrary regular cardinal in $L_\beta$, we have shown that $\alpha$ is remarkable in $L_\beta$.

\[\square \ (2.2)\]

As an immediate corollary to this proof we get:
Lemma 2.3 Suppose that $0^\sharp$ exists. Then every Silver indiscernible is remarkable in $L$.

Proof. A slight variation of the previous proof gives that $L_\beta \models "\alpha \text{ is remarkable}"$ whenever $\alpha < \beta$ are both indiscernibles for $L$. But then every Silver indiscernible is remarkable in $L$.

□ (2.3)

Lemma 2.4 Let $\kappa$ be remarkable. Then there are $\alpha < \beta < \omega_1$ such that $L_\beta \models "ZFC + \alpha \text{ is a ineffable cardinal}"$.

Proof. Let $\theta = \kappa^+$, and let $\pi$, $\alpha$, and $N$ be as in 2.1. Let $\alpha = \pi^{-1}(\kappa)$ and let $\beta = \sigma(\alpha)$. It is easy to see that $L_\beta \models ZFC$. We claim that $\alpha$ is ineffable in $L_\beta$.

Let $(A_i : i < \alpha) \in L_\beta$ be such that $A_i \subseteq i$ for all $i < \alpha$, and let $C \in L_\beta$ be club in $\alpha$. There is $(A_i : \alpha \leq i < \beta)$ such that $\sigma((A_i : i < \alpha)) = (A_i : i < \beta)$. Notice that $A_\alpha \in N$, as $\mathcal{P}(\alpha) \cap N = \mathcal{P}(\alpha) \cap M$ by the properties of $M$, $\sigma$, and $N$. Now of course $A_\alpha = \sigma(A_\alpha) \cap \alpha$, and also $\alpha \in \sigma(C)$. This gives that $\alpha \in \sigma(\{i < \alpha : A_i = A_\alpha \cap i\}) \cap \sigma(C)$, and thus via $\sigma$ we have that $\{i < \alpha : A_i = A_\alpha \cap i\} \cap C \neq \emptyset$. As $C$ was arbitrary, we have shown that $\alpha$ is ineffable in $L_\beta$.

□ (2.4)

We now turn towards a useful characterization of remarkability.

Definition 2.5 Let $\kappa$ be a cardinal. Let $G$ be $Col(\omega, < \kappa)$-generic over $V$, let $\theta > \kappa$ be a regular cardinal, and let $X \in [H^V[G])^\omega$. We say that $X$ condenses remarkably if $X = \text{ran}(\pi)$ for some elementary

$$\pi : (H^V_{\beta}; \in, H^V_{\beta}, G \cap H^V_{\alpha}) \to (H^V_{\theta}; \in, H^V_{\theta}, G)$$

where $\alpha = \text{crit}(\pi) < \beta < \kappa$ and $\beta$ is a regular cardinal.

Notice that in the situation of 2.3 we will have that $\alpha$ is inaccessible in $V$, $G \cap H^V_\alpha$ is $Col(\omega, < \alpha)$-generic over $V$, and hence $\beta$ is a regular cardinal in $V[G \cap H^V_\alpha]$, too.

Lemma 2.6 A cardinal $\kappa$ is remarkable if and only if for all regular cardinals $\theta > \kappa$ do we have that

$$\models_{Col(\omega, < \kappa)} \{X \in [H^V_{\theta}]^\omega : X \text{ condenses remarkably} \} \text{ is stationary.}$$
Proof. ”⇒.” Let κ be remarkable, and let θ > κ be a regular cardinal. We may pick π: M → Hθ⁺ as in 2.1, but with θ⁺ playing the role of θ. Let k, θ = π⁻¹(κ, θ), and let σ: M → N with critical point k be such that N is countable and transitive, ρ = M ∩ OR is regular in N, M = Hρ, and σ(k) > ρ. In V, we may pick G being Col(ω, < k)-generic over M (and hence over N), and we may pick G' ⊇ G^ being Col(ω, < σ(k))-generic over N. We then have that σ naturally extends to \( \hat{\sigma}: M[G] → N[G'] \).

Let \( \mathcal{M} = (H^M, \in, H^M, G, (R_i: i < n)) \in M[G] \) be any model of finite type. Notice that \( \mathcal{M} \in N[G'] \) and is countable there. By the existence of \( \hat{\sigma} \upharpoonright H^M: \mathcal{M} → \hat{\sigma}(\mathcal{M}) \) together with 1.2, we get that in \( N[G'] \) there is an elementary embedding \( \tau \) of \( \mathcal{M} \) into \( \hat{\sigma}(\mathcal{M}) \). This means that

\[ N[G'] \models \exists \alpha < \beta < \sigma(\hat{\kappa}) \exists \tau (\tau: \langle H^V, \in, \ldots \rangle → \hat{\sigma}(\mathcal{M}) ∧ \beta \text{ is regular }). \]

Pulling this back via \( \hat{\sigma} \) gives that

\[ M[G] \models \exists \alpha < \beta < \kappa \exists \tau (\tau: \langle H^V, \in, \ldots \rangle → \mathcal{M} ∧ \beta \text{ is regular }). \]

As \( \mathcal{M} \) was arbitrary, we have shown that

\[ \|−M_{Col(\omega, < k)} \{ X ∈ [H^M]\omega: X \text{ condenses remarkably } \} \| \text{ is stationary.} \]

Lifting this up via \( \pi \) gives

\[ \|−V_{Col(\omega, < k)} \{ X ∈ [H^V]\omega: X \text{ condenses remarkably } \} \| \text{ is stationary.} \]

As \( \theta \) was arbitrary, this proves ”⇒.”

”⇐.” Let \( \theta > \kappa \) be a regular cardinal, and suppose that

\[ \|−V_{Col(\omega, < k)} \{ X ∈ [H^V]\omega: X \text{ condenses remarkably } \} \| \text{ is stationary.} \]

Let \( \tilde{\pi}: \tilde{M} → Hθ⁺ \) with \( M \) countable and transitive be such that \( \kappa, \theta ∈ ran(\tilde{\pi}) \). Let \( \tilde{k}, \tilde{\theta} = \tilde{\pi}⁻¹(\kappa, \theta) \). In \( V \), we may pick \( G \) being Col(ω, < \tilde{k})-generic over \( \tilde{M} \). Because inside \( \tilde{M}[G] ⊆ V \) we get some \( \bar{\sigma}: \tilde{H}^\tilde{M} → H^{\tilde{M}} \) such that \( \rho \) is a regular cardinal in \( \tilde{M} \) with \( \rho < \tilde{k} \).

Now set \( M = H^M, N = H^M, \sigma = \bar{\sigma}, \) and \( \pi = \tilde{\pi} ∘ \bar{\sigma} \). Then \( \pi, M, \sigma, \tilde{\theta}, \) and \( N \) are as in 2.1. As \( \theta \) was arbitrary, this proves ”⇐.”

□ (2.3)
Lemma 2.7 Let $\kappa$ be remarkable. Then $L \models "\kappa$ is remarkable."

Proof. Let $\theta > \kappa$ be a regular cardinal in $L$. Let $G$ be $\text{Col}(\omega, < \kappa)$-generic over $V$, and let $\mathcal{M} = (L_{\theta}[G]; \in, \bar{R}) \in L[G]$ be any model of finite type. Let $\mathcal{N} = (H^{V[G]}_{\theta^+}; \in, H^{V[G]}_{\theta^+}, G, L_{\theta}[G], \bar{R})$. As $\kappa$ is remarkable, in $V[G]$ we may pick some

$$\pi: (H^{V[G \cap H_{\alpha}]}_{\beta}; \in, H^{V[G \cap H_{\alpha}]}_{\beta}, G \cap H_{\alpha}, L_{\theta}[G \cap L_{\alpha}], \bar{R}) \rightarrow \mathcal{N}$$

where $\alpha = \text{crit}(\pi) < \beta < \kappa$ and $\beta$ is a regular cardinal in $V$. Then

$$\pi \upharpoonright L_{\theta}[G \cap L_{\alpha}]: (L_{\theta}[G \cap L_{\alpha}], \in, \bar{R}) \rightarrow \mathcal{M},$$

and $\bar{\theta}$ is a regular cardinal in $L$. Because $L_{\theta}[G \cap L_{\alpha}] \in L[G]$ and is countable there, and the existence of $\pi \upharpoonright L_{\theta}[G \cap L_{\alpha}]$ yield that inside $L[G]$ there are predicates $\bar{S}$ on $L_{\theta}[G \cap L_{\alpha}]$ together with an elementary embedding

$$\sigma: (L_{\theta}[G \cap L_{\alpha}], \in, \bar{S}) \rightarrow \mathcal{M}.$$ 

I.e., $(\text{ran}(\sigma) ; \in, \bar{R} \upharpoonright \text{ran}(\sigma)) \prec \mathcal{M}$ where $\text{ran}(\sigma) \in L[G]$. As $\theta$ and then $\mathcal{M}$ were arbitrary we have shown that in $L$ does $\kappa$ satisfy the characterization of remarkability from 2.6.

\[ \Box \ (2.7) \]

3 \ $L(\mathbb{R})$ absoluteness.

Lemma 3.1 Let $\kappa$ be remarkable in $L$. Let $G$ be $\text{Col}(\omega, < \kappa)$-generic over $L$. Let $P \in L[G]$ be a proper poset, and let $H$ be $P$-generic over $L[G]$. Then for every real $x$ in $L[G][H]$ there is a poset $Q_x \in L_\kappa$ such that $x$ is $Q_x$-generic over $L$.

Proof. Let $\theta > \kappa$ be an $L$-cardinal such that $\mathcal{P}(P) \subset L_\theta[G]$. Let $x \in \mathbb{R} \cap L[G][H]$, and let $\hat{x} \in L_\theta[G]$ be such that $\hat{x}^H = x$. Consider the structure $\mathcal{M} = (L_\theta[G]; \in, \hat{P}, \hat{x}, H)$. Because $\kappa$ is remarkable in $L$ and $P$ is proper we may pick an elementary

$$\pi: (L_\beta[G \cap L_{\alpha}]; \in, \hat{P}, \hat{x}, H) \rightarrow \mathcal{M}$$

with the property that $G \cap L_{\alpha}$ is $\text{Col}(\omega, < \alpha)$-generic over $L$ and $\beta$ is an $L[G \cap L_{\alpha}]$-cardinal. By elementarity, $\hat{H}$ is $\hat{P}$-generic over $L_\beta[G \cap L_{\alpha}]$, and hence over $L[G \cap L_{\alpha}]$, as $\mathcal{P}(P) \cap L[G \cap L_{\alpha}] \subset L_\beta[G \cap L_{\alpha}]$. Moreover, by the definability of forcing, we get

$$n \in \hat{x}^H \text{ iff } \exists p \in \hat{H} \ p \models \bar{n} \in \bar{x} \text{ iff } \exists p \in H \ p \models \bar{n} \in \hat{x} \text{ iff } n \in \hat{x}^H \text{ iff } n \in x.$$
So $\dot{x}^H = x$, and we may set $Q_x = \text{Col}(\omega, < \alpha) \star \dot{P}$ where $\dot{P}^H = \dot{P}$. Notice that $Q_x \in L_\kappa$.

□ (3.1)

**Lemma 3.2** Let $\kappa$ be remarkable in $L$. Let $G$ be $\text{Col}(\omega, < \kappa)$-generic over $L$. Let $P \in L[G]$ be a proper poset, and let $H$ be $P$-generic over $L[G]$. Let $E$ be $\text{Col}(\omega, (2^{\aleph_0})^{L[G][H]})$-generic over $L[G][H]$. Then in $L[G][H][E]$ there is some $G'$ being $\text{Col}(\omega, < \kappa)$-generic over $L$ such that

$$\mathbb{R} \cap L[G'] = \mathbb{R} \cap L[G][H].$$

**Proof.** Let $(e_i : i < \omega) \in L[G][H][E]$ be such that $\{e_i : i < \omega \} = \mathbb{R} \cap L[G][H]$. By working inside $L[G][H][E]$ we may easily use 3.1 to construct $(\alpha_i, G_i : i < \omega)$ such that $\alpha_0 < \alpha_1 < ...$ and for all $i < \omega$ we have that $G_i$ is $\text{Col}(\omega, < \alpha_i)$-generic over $L$, $G_{i-1} \subseteq G_i$ (with the convention that $G_{-1} = \emptyset$), $G_i \in L[G][H]$, and $e_i \in L[G_i]$. Set $G' = \bigcup_i G_i$.

Because $\text{Col}(\omega, < \kappa)$ has the $\kappa$-c.c., $G'$ is $\text{Col}(\omega, < \kappa)$-generic over $L$, and every real in $L[G']$ is in $L[G_i]$ for some $i < \omega$. We get that $\mathbb{R} \cap L[G'] = \mathbb{R} \cap L[G][H]$ as desired.

□ (3.2)

**Theorem 3.3** (Embedding theorem in $L[G]$) Let $\kappa$ be remarkable in $L$. Let $G$ be $\text{Col}(\omega, < \kappa)$-generic over $L$, and write $V = L[G]$. Then in $V$ the $L(\mathbb{R})$ embedding theorem holds for proper forcings.

**Proof.** Let $P \in V$ be a proper poset, and let $H$ be $P$-generic over $V$. By 3.2 (in some further extension) there is $G'$ being $\text{Col}(\omega, < \kappa)$-generic over $L$ such that $\mathbb{R} \cap L[G'] = \mathbb{R} \cap V[H]$. Let $\phi(\bar{v}, \bar{w})$ be a formula, let $\bar{x} \in \mathbb{R} \cap V$, and let $\bar{\alpha} \in OR$. We then have that

$$L(\mathbb{R}^V) \models \phi(\bar{x}, \bar{\alpha}) \iff \models_{\text{Col}(\omega, < \kappa)} L(\mathbb{R}) \models \phi(\bar{x}, \bar{\alpha}) \iff L(\mathbb{R}^{V[H]}) \models \phi(\bar{x}, \bar{\alpha}).$$

□ (3.3)
Theorem 3.4 (Anti-coding theorem in \(L[G]\)) Let \(\kappa\) be remarkable in \(L\). Let \(G\) be \(\text{Col}(\omega, < \kappa)\)-generic over \(L\), and write \(V = L[G]\). Then in \(V\) the \(L(\mathbb{R})\) anti coding theorem holds for proper forcings.

Proof. Let \(P \in V\) be a proper poset, and let \(H\) be \(P\)-generic over \(V\). By Theorem 3.4 it suffices to show that each \(A \in L(\mathbb{R}^{[H]}) \cap V\) is also in \(L(\mathbb{R})\). Fix such an \(A\), and let \(\Phi\) a formula, \(\vec{\alpha}\) over \(L\), \(\vec{\beta}\) over \(L\). Let \(\bar{\hat{\alpha}}\in OR\), and \(x \in \mathbb{R}^{[H]}\) be such that

\[
\gamma \in A \iff L(\mathbb{R}^{[H]}) \models \Phi(\bar{\hat{\alpha}}, x, \gamma).
\]

Let \(\hat{x}^H = x\), and assume w.l.o.g. that

\[
(\star) \quad \emptyset \models_{\hat{\mathfrak{P}}^L} \gamma \in \bar{\hat{A}} \iff L(\hat{\mathbb{R}}) \models \Phi(\bar{\hat{\alpha}}, \hat{x}, \gamma).
\]

As in the proof of 3.3, we may pick an elementary

\[
\pi: (L_{\beta \mid G \cap L_{\alpha}}; \in, \bar{\hat{P}}, \bar{\hat{x}}, \bar{\hat{H}}) \to (L_{\beta \mid G}; \in, P, \hat{x}, H)
\]

such that \(\beta\) is an \(L[G \cap L_{\alpha}]\)-cardinal. Because \(L_{\beta \mid G \cap L_{\alpha}}\) is countable in \(V\) we may pick \(h \in V\) being \(\bar{\hat{P}}\)-generic over \(L_{\beta \mid G \cap L_{\alpha}}\). Of course, \(h\) will then also be \(\bar{\hat{P}}\)-generic over \(L[G \cap L_{\alpha}]\). Because \(P\) is proper we may and shall assume w.l.o.g. that (inside some further forcing extension) for every \(p \in \bar{\hat{P}}\) there is \(G^p\) being \(P\)-generic over \(V\) with \(\pi(p) \in G^p\) and such that \(\pi^{-1}G^p\) is \(\bar{\hat{P}}\)-generic over \(L_{\beta \mid G \cap L_{\alpha}}\) (i.e., over \(L[G \cap L_{\alpha}]\)). Notice that \(\hat{x}^G = x\) for every \(p \in \bar{\hat{P}}\). In order to prove 3.4 it now clearly suffices to verify the following.

Claim. For all \(\gamma \in OR\), \(\gamma \in A \iff \models_{L[G \cap L_{\alpha}][\bar{\hat{h}}]} L(\hat{\mathbb{R}}) \models \Phi(\bar{\hat{\alpha}}, \bar{\hat{x}}, \gamma).

Proof. We shall prove "\(\Leftarrow\)". The proof of "\(\Rightarrow\)" is almost identical in that it starts from \(\neg \Phi\) instead of from \(\Phi\), and gives \(\gamma \notin A\) instead of \(\gamma \in A\). Suppose that

\[
\models_{L[G \cap L_{\alpha}][\bar{\hat{h}}]} L(\hat{\mathbb{R}}) \models \Phi(\bar{\hat{\alpha}}, \bar{\hat{x}}, \gamma).
\]

This is itself forced by some \(p \in \bar{\hat{h}}\), and thus we also get, writing \(G^p = \pi^{-1}G^p\), that

\[
\models_{L[G \cap L_{\alpha}][G^p]} L(\hat{\mathbb{R}}) \models \Phi(\bar{\hat{\alpha}}, \bar{\hat{x}}^{G^p}, \gamma).
\]

Because \(G^p = \pi^{-1}G^p \in L[G][G^p]\), in much the same way as in the proof of 3.3 we can pick (inside some further forcing extension) some \(G'\) being \(\text{Col}(\omega, < \kappa)\)-generic over \(L[G \cap L_{\alpha}][G^p]\) such that

\[
\mathbb{R} \cap L[G \cap L_{\alpha}][G^p][G'] = \mathbb{R} \cap L[G][G^p].
\]
Hence
\[ L(\mathbb{R}^{V[G^p]}) \models \Phi(\vec{\alpha}, \vec{x}^{G^p}, \gamma). \]

But \( \vec{x}^{G^p} = \check{x}^{G^p} \), so that there is some \( q \in G^p \) such that
\[ q \models \bigwedge P L(\check{R}) \models \Phi(\check{\alpha}, \check{x}, \check{\gamma}). \]

Hence, by (*), \( q \models \bigwedge P \gamma \in \check{A} \), which implies that \( \gamma \in A \).

\( \square \) (Claim)

\( \square \) (3.4)

Here is an immediate corollary to 3.3 and 3.4, when combined with 2.7.

**Corollary 3.5** Neither the conclusion of the \( L(\mathbb{R}) \) embedding theorem for proper forcings nor the conclusion of the \( L(\mathbb{R}) \) anti coding theorem for proper forcings implies \( \Pi^1_1 \)-determinacy.

### 4 An equiconsistency.

**Definition 4.1** Let \( A \subset OR \). We say that \( A \) is good if \( A \subset \omega_1 \) and \( L_{\omega_2}[A] = H_{\omega_2} \).

**Lemma 4.2** If \( 0^\sharp \) does not exist then there is a proper \( P \in V \) such that
\[ \models \bigwedge P \ "there is a good A." \]

**Proof.** This uses almost disjoint forcing in its simplest form. Fix \( \delta \), a singular cardinal of uncountable cofinality and such that \( \delta^{<\omega_0} = \delta \) (for example, let \( \delta \) be a strong limit). By Jensen’s Covering Lemma, we know that \( \delta^+ = \delta^+ \). We may also assume w.l.o.g. that \( 2^{\delta} = \delta^+ \), because otherwise we may collapse \( 2^{\delta} \) onto \( \delta^+ \) by a \( \delta \)-closed preliminary forcing. We may hence pick \( B \subset \delta^+ \) with the property that \( H_{\delta^+} = L_{\delta^+}[B] \).

Now let \( G_1 \) be \( Col(\delta, \omega_1) \)-generic over \( V \). Notice that the forcing is \( \omega \)-closed. Set \( V_1 = V[G_1] \). We have that \( \omega_2^{V_1} = \delta^+ = \delta^+ \). Let \( C \subset \omega_1 \) code \( G_1 \) (in the sense that \( G_1 \in L_{\omega_2}[C] \)). Using the fact that \( Col(\delta, \omega_1) \) has the \( \delta^+ \)-c.c., it is easy to verify that in \( V_1 \), \( H_{\omega_2} = L_{\omega_2}[B, C] \). Let \( \omega_2 \) denote \( \omega_2^{V_2} \) from now on.

In \( L \) we may pick \( (A'_\xi : \xi < \delta^+) \), a sequence of almost disjoint subsets of \( \delta \). In \( L_{\omega_2}[C] \) we may pick a bijective \( g: \omega_1 \rightarrow \delta \). Then if we let \( \alpha \in A_\xi \) iff \( g(\alpha) \in A'_\xi \) for \( \alpha < \omega_1 \) and \( \xi < \delta^+ \), we have that \( (A_\xi : \xi < \delta^+) \) is a sequence of almost disjoint subsets of \( \omega_1 \).
In $V_1$, we may pick $D \subset \omega_2$ with $H_{\omega_2} = L_{\omega_2}[B,C] = L_{\omega_2}[D]$ (for example, the "join" of $A$ and $B$). We let $P_2$ be the forcing for coding $D$ by a subset of $\omega_1$, using the almost disjoint sets $A_\xi$.

To be specific, $P_2$ consists of pairs $p = (l(p), r(p))$ where $l(p): \alpha \to 2$ for some $\alpha < \omega_1$ and $r(p)$ is a countable subset of $\omega_2$. We have $p = (l(q), r(q))$ iff $l(p) \supset l(q)$, $r(p) \supset r(q)$, and for all $\xi \in r(q)$, if $\xi \in D$ then

$$\{ \beta \in \text{dom}(l(p)) \setminus \text{dom}(l(q)) : l(p)(\beta) = 1 \} \cap A_\xi = \emptyset.$$ 

By a $\Delta$-system argument, $P_2$ has the $\omega_2$-c.c. It is clearly $\omega$-closed, so no cardinals are collapsed. Moreover, if $G_2$ is $P_2$-generic over $V_1$, and if we set

$$A = \bigcup_{p \in G_2} \{ \beta \in \text{dom}(l(p)) : l(p)(\beta) = 1 \},$$

then $A \subset \omega_1$ and we have that for all $\xi < \omega_2$,

$$\xi \in A_1 \text{ iff } Card(A \cap A_\xi) \leq \aleph_0.$$ 

This means that $A_1$ is an element of any inner model containing $(A_\xi : \xi < \omega_2)$ and $A$. (Of course, much more holds.) An example of such a model is $L[D]$ in the sense explained above. Set $V_2 = V_1[G_2]$. Moreover, because $P_2$ has the c.c.c., we get that in $V_2$, $H_{\omega_2} = L_{\omega_2}[A]$.

Recall that all the forcings we have used to obtain $V_2$ were either $\omega$-closed or had the c.c.c. Hence $V_2$ is a proper set-generic extension of $V$.

$\square$ \textbf{(4.2)}

It is easy to see that the conclusion of \textbf{(4.2)} is actually equivalent with the property that $V$ is not closed under $\sharp$'s.

**Definition 4.3** Let $A \subset \omega_1$. By $\nabla(A)$ we denote the assertion that

$$\{ X \in [L_{\omega_2}[A]]^\omega : \exists \alpha < \beta \in \text{Card}L_{[A \cap \alpha]} \exists \pi : L_{\beta}[A \cap \alpha] \to X < L_{\omega_2}[A] \}$$

is stationary in $[L_{\omega_2}[A]]^\omega$.

**Theorem 4.4** Suppose that $L(\mathbb{R})$ is absolute under proper forcings. Then

$$\forall A \ (A \text{ good } \Rightarrow \nabla(A))$$

holds in all proper set-generic extensions of $V$.

11
Proof. Let $\Psi$ denote the statement that the reals can be well-ordered in $L(\mathbb{R})$. By adding $\omega_1$ Cohen reals with finite support, which is proper, one obtains an extension of $V$ in which $\Psi$ fails. Hence if $L(\mathbb{R})$ is supposed to be absolute under proper forcings, $\Psi$ has to fail in $V$ to begin with, and it has to fail in every proper set-forcing extension of $V$.

Let us now fix a good $A$ such that $\nabla(A)$ fails. We shall define a proper forcing $P \in V$ such that

$$\Vdash \neg \Psi.$$  

This will give a contradiction, and prove 4.4 in $V$; of course, by replacing $V$ by a proper set-forcing extension of itself, the very same argument will prove the full 4.4.

The key observation here is that $\neg \nabla(A)$ implies that ”reshaping” our good $A$ is proper. We let $P_1$ consist of functions $p: \alpha \to 2$ with $\alpha < \omega_1$ and such that for all $\xi \leq \alpha$ we have that

$$L[A \cap \xi, p \upharpoonright \xi] \models Card(\xi) \leq \aleph_0.$$  

This is the classical forcing for reshaping $A$ (cf. [1]). We need the following.

Claim. $P_1$ is proper.

Proof. Let us consider $M = (L_{\omega_2}[A]; \in, A)$. Because $\nabla(A)$ fails, there is a club $C \subset [H_{\omega_2}]^{\omega}$ such that for all $X \in C$, if $\pi: (L_\beta[A \cap \alpha]; \in, A \cap \alpha) \cong (X; \in, A \cap X) \prec M$ then $\beta$ is not a cardinal in $L[A \cap \alpha]$. Let us fix some such $X$. We have to show that for any $p \in P_1 \cap X$ there is $q \leq_{P_1} p$ which is $(P, X)$-generic.

For this we use an argument of [6]. Let $(\dot{\alpha}_i: i < \omega)$ enumerate the ordinal names in $X$. We shall produce $q \leq_{P_1} p$ such that for all $i < \omega$ we have that $q \Vdash \dot{\alpha}_i \in X$. We may assume w.l.o.g. that $\alpha = \omega_1^{L[A \cap \alpha]}$, as otherwise the task of constructing $q$ turns out to be an easier variant of what is to follow. Now as $\beta$ has size $\alpha$ in $L[A \cap \alpha]$ we may pick a club $E \subset \alpha$ in $L[A \cap \alpha]$ which grows faster than all clubs in $L_\beta[A \cap \alpha]$, i.e., whenever $\bar{E} \subset \alpha$ is a club in $L_\beta[A \cap \alpha]$ then $E \setminus \bar{E}$ is bounded in $\alpha$.

Inside $L[A \cap \alpha]$, we are now going to construct a sequence $(p_i : i < \omega)$ of conditions below $p$ such that $p_{i+1} \leq_{P_1} p_i$ and $p_{i+1} \Vdash \dot{\alpha}_i \in X$. We also want to maintain inductively that $p_{i+1} \in L_\beta[A \cap \alpha]$. (Notice that $p \in L_\beta[A \cap \alpha]$ to begin with.) In the end we also want to have that setting $q = \bigcup_{i<\omega} p_i$, we have that $q \in P_1$, which of course is the the non-trivial part. For this purpose, we also pick $(\dot{\alpha}_i: i < \omega)$ cofinal in $\alpha$.

To commence, let $p_0 = p$. Now suppose that $p_i$ is given, $p_i \in L_\beta[A \cap \alpha]$. Set $\gamma = \text{dom}(p_i) < \alpha$. Work inside $L_\beta[A \cap \alpha]$ for a minute. For all $\delta$ such that $\gamma < \delta < \alpha$
we may pick some \( p^\delta \leq P_i \) such that: \( p^\delta \models \pi^{-1}(\bar{\delta}_i) \in L_\beta[A \cap \alpha] \), \( dom(p^\delta) \geq \bar{\alpha}_i \), \( dom(p^\delta) > \delta \), and for all limit ordinals \( \lambda, \gamma \leq \lambda \leq \delta \), \( p^\delta(\lambda) = 1 \) iff \( \lambda = \delta \). Then there is \( \bar{E} \) club in \( \alpha \) such that for any \( \eta \in \bar{E}, \delta < \eta \Rightarrow dom(p^\delta) < \eta \).

Now back in \( L[A \cap \alpha] \), we may pick \( \delta \in E \) such that \( E \setminus \bar{E} \subset \delta \). Set \( p_{i+1} = p^\delta \), and let for future reference \( \delta = \delta_{i+1} \). Of course \( p_{i+1} \models \neg \bar{\alpha}_i \in X \). We also have that \( dom(p_{i+1}) < \min\{\epsilon \in E : \epsilon > \delta\} \), so that for all limit ordinals \( \lambda \in E \cap (dom(p_{i+1}) \setminus dom(p_i)) \) we have that \( p_{i+1}(\lambda) = 1 \) iff \( \lambda = \delta_{i+1} \).

Now set \( q = \cup_{i<\omega} p_i \). We are done if we can show that \( q \) is a condition. Well, it is easy to see that we have arranged that \( dom(q) = \alpha \), so that the only problem here is to show that

\[
L[A \cap \alpha, q] \models Card(\kappa) \leq \aleph_0.
\]

But by the construction of the \( p_i \)'s we have that

\[
\{\lambda \in E \cap (dom(q) \setminus dom(p)) : \lambda \text{ is a limit ordinal and } q(\lambda) = 1\}
= \{\delta_{i+1} : i < \omega\},
\]

being a cofinal subset of \( E \). But \( E \) is an element of \( L[A \cap \alpha, q] \), so that \( \{\delta_{i+1} : i < \omega\} \in L[A \cap \alpha, q] \) witnesses that \( Card(\alpha) \leq \aleph_0 \).

We have shown that \( q \in P_1 \) is \( (P, X) \)-generic, as desired.

\(\square\) (Claim)

Now let \( G \) be \( P_1 \)-generic over \( V \), and pick \( D \subset \omega_1 \) such that \( L_{\omega_2}[D] = L_{\omega_2}[A, G] \).

We may now ”code down to a real” by using almost disjoint forcing. By the fact that \( D \) is ”reshaped,” there is a (unique) sequence \((a_\beta : \beta < \omega_1)\) of subsets of \( \omega \) such that for each \( \beta < \omega_1 \), \( a_\beta \) is the \( L[D \cap \beta] \)-least subset of \( \omega \) being almost disjoint from any \( a_{\bar{\beta}} \) for \( \bar{\beta} < \beta \).

We then let \( P_2 \) consist of all pairs \( p = (l(p), r(p)) \) where \( l(p) : n \to 2 \) for some \( n < \omega \) and \( r(p) \) is a finite subset of \( \omega_1 \). We let \( p = (l(p), r(p)) \leq P_2 \) \( q = (l(q), r(q)) \) iff \( l(p) \supset l(q), r(p) \supset r(q) \), and for all \( \beta \in r(q) \), if \( \beta \in D \) then

\[
\{\gamma \in dom(r(p)) \setminus dom(r(q)) : r(p)(\gamma) = 1\} \cap a_\beta = \emptyset.
\]

By a \( \Delta \)-system argument, \( P_1 \) has the c.c.c.. Moreover, if \( H \) is \( P_2 \)-generic over \( V[G] \), and if we set

\[
a = \bigcup_{p \in H} \{\gamma \in dom(l(p)) : l(p)(\gamma) = 1\},
\]

then we have that for \( \gamma < \omega_1 \),

\[
\gamma \in D \text{ iff } Card(a \cap a_\gamma) < \aleph_0.
\]
Moreover, because $P_2$ has the c.c.c., we get that in $V[G][H]$ we have that $H_{\omega_2} = L_{\omega_2}[a]$.

In particular, $R \cap V[G][H] \subset L[a]$ which implies that in $V[G][H]$ there is a $\Delta^1_2(a)$-well-ordering of the reals. Thus, if we set $P = P_1 \star P_2$ then $P$ is proper and $\parallel \neg P \Psi$.

\[\square (4.4)\]

**Lemma 4.5** Suppose that $L(\mathbb{R})$ is absolute under proper forcings. Then $\omega_1$ is remarkable in $L$.

**Proof.** By 2.3, we may assume that $0^\sharp$ does not exist. Let $\theta > \kappa$ be an $L$-cardinal. Using 4.2 we may easily find a proper set-forcing extension of $V$ in which there is a good $B$ and in which $\theta < \omega_2$ (just primarily force with $Col(\omega_1, \theta)$, which is $\omega$-closed). By finally forcing with $Col(\omega, < \omega_1)$ (which has the c.c.c.) we get a proper set-forcing extension of $V$ in which we may pick a good $A$ such that $A_{odd} = \{2\delta + 1 \in A: \delta < \omega_1\}$ essentially is $Col(\omega, < \omega_1)$-generic over $L$, and $\theta < \omega_2$. By 4.4 we know that in that extension,

$$\{X \in [L_{\omega_2}[A]]^\omega: \exists \alpha < \beta \in Card^{L[A \cap \alpha]} \exists \pi \pi: L_\beta[A \cap \alpha] \rightarrow X \prec L_{\omega_2}[A]\}$$

is stationary in $[L_{\omega_2}[A]]^\omega$. We may now argue exactly as in the proof of 2.7 to see that this implies that $\omega_1$ has to be remarkable in $L$.

\[\square (4.5)\]

**Corollary 4.6** The following are equiconsistent.

1. $L(\mathbb{R})$ is absolute under proper forcings.
2. The $L(\mathbb{R})$ embedding theorem holds for proper forcings.
3. The $L(\mathbb{R})$ anti coding theorem holds for proper forcings.
4. There is a remarkable cardinal.

**Proof.** $\text{Con}(1) \Rightarrow \text{Con}(4)$ is 1.5. $\text{Con}(4) \Rightarrow \text{Con}(2)$ and $\text{Con}(4) \Rightarrow \text{Con}(3)$ are 3.3 and 3.4. $\text{Con}(3) \Rightarrow \text{Con}(4)$ follows from the proofs of 1.2 and 4.4. $\text{Con}(2) \Rightarrow \text{Con}(1)$ is trivial.

\[\square (4.6)\]
5 A derived model theorem.

We have shown in 3.3 that there is a model of \(L(R)\) absoluteness under proper forcings which is of the form \(L[G]\) where \(G\) is \(Col(\omega, < \kappa)\)-generic over \(L\) for some inaccessible \(\kappa\) in \(L\). We are now going to show that – under some genericity assumption – every model of \(L(R)\) absoluteness under proper forcings is of this form.

**Definition 5.1** We let \((\natural)\) denote the assertion that every real is set-generic over \(L\), i.e., that for every \(x \in \mathbb{R}\) there is some poset \(P \in L\) and some \(G \in V\) being \(P\)-generic over \(L\) such that \(x \in L[G]\).

**Theorem 5.2** (Derived model theorem) Assume that \((\natural)\) holds and that \(L(R)\) is absolute under proper forcings. Then (in some set-generic extension of \(V\)) there is \(G\) being \(Col(\omega, < \omega_1^V)\)-generic over \(L\) such that \(L(R^V) = L(R^{L[G]})\).

**Proof.** By 4.2 and 4.4 there is \(V[H]\), a proper set-generic extension of \(V\), in which there is a good \(A\), and \(\forall(A)\) holds. By \((\natural)\), for every \(x \in \mathbb{R}^V\) we may pick a poset \(P_x \in L\) and some \(K_x \in V\) being \(P_x\)-generic over \(L\) such that \(x \in L[K_x]\). Let \(\theta_x\) be such that \(P_x \in H_{\theta_x}\). By primarily forcing with \(Col(\omega_1, sup_{x \in \mathbb{R}}(Card(P)))\) we may assume w.l.o.g. that any \(P_x\) is hereditarily smaller than \(\omega_2\) in \(V[H]\), i.e., \(P_x \in L(\omega_2[A])\) for every \(x \in \mathbb{R}^V\).

Now fix \(x \in \mathbb{R}^V\), and set \(\mathcal{M} = (L_{\omega_2}[A]; \in, A, P_x, K_x, \dot{x})\) where \(\dot{x}^{K_x} = x\). Using \(\forall(A)\) there is some

\[
\pi: (L_\beta[A \cap \alpha]; \in, A \cap \alpha, \bar{P}_x, \bar{K}_x, \bar{x}) \rightarrow \mathcal{M}
\]

such that \(\beta\) is a cardinal in \(L[A \cap \alpha]\), and hence so in \(L\). We get that \(x = (\bar{x})^{K_x} \in L[\bar{K}_x]\) where \(\bar{K}_x\) is \(\bar{P}_x\)-generic over \(L\), and \(\bar{P}_x\) is countable. Notice that \(\pi\) only exists in \(V[H]\). However, by 4.2 we may then also find, inside \(V\), some

\[
\sigma: (L_\beta; \in, \bar{P}_x, \bar{K}_x, \bar{x}) \rightarrow \mathcal{M},
\]

so that \(x = (\bar{x})^{\bar{K}_x} \in L[\bar{K}_x]\) where \(\bar{K}_x\) is \(\bar{P}_x\)-generic over \(L\), and \(\bar{P}_x\) is countable.

But now, as in the proof of 3.2, in a \(Col(\omega, (2^{\omega_0})^{V})\)-generic extension of \(V\) we may construct \(G\) being \(Col(\omega, < \omega_1^V)\)-generic over \(L\) such that \(L(R^V) = L(R^{L[G]})\).

\(\Box\) (5.2)

**Corollary 5.3** Assume that \((\natural)\) holds and that \(L(\mathbb{R})\) is absolute under proper forcings. Then every set of reals in \(L(\mathbb{R})\) is Lebesgue measurable and has the property of Baire.
