EIGENVALUES OF THE LAPLACIAN ACTING ON $p$-FORMS
AND METRIC CONFORMAL DEFORMATIONS

BRUNO COLBOIS AND AHMAD EL SOUFI

(Communicated by Jozef Dodziuk)

Abstract. Let $(M,g)$ be a compact connected orientable Riemannian mani-
fold of dimension $n \geq 4$ and let $\lambda_{k,p}(g)$ be the $k$-th positive eigenvalue of the
Laplacian $\Delta_{g,p} = dd^* + d^*d$ acting on differential forms of degree $p$ on $M$. We
prove that the metric $g$ can be conformally deformed to a metric $g'$, having
the same volume as $g$, with arbitrarily large $\lambda_{1,p}(g')$ for all $p \in [2, n-2]$.

Note that for the other values of $p$, that is $p = 0, 1, n-1$ and $n$, one can
deduce from the literature that, $\forall k > 0$, the $k$-th eigenvalue $\lambda_{k,p}$ is uniformly
bounded on any conformal class of metrics of fixed volume on $M$.

For $p = 1$, we show that, for any positive integer $N$, there exists a metric
$g_N$ conformal to $g$ such that, $\forall k \leq N$, $\lambda_{k,1}(g_N) = \lambda_{k,0}(g_N)$, that is, the first
$N$ eigenforms of $\Delta_{g_N,1}$ are all exact forms.

1. Introduction and statement of results

Let $M$ be a closed connected orientable differentiable manifold of dimension
$n \geq 2$. For any Riemannian metric $g$ on $M$, we denote by $\Delta_{g,p} = dd^* + d^*d$
the corresponding Laplacian acting on differential forms of degree $p$ on $M$. The
spectrum $\text{spec}(\Delta_{g,p})$ of $\Delta_{g,p}$ consists of an unbounded sequence of nonnegative
eigenvalues which starts from zero if and only if the $p$-th Betti number $b_p(M)$ of $M$
does not vanish. The sequence of positive eigenvalues of $\Delta_{g,p}$ is denoted by

$$0 < \lambda_{1,p}(g) \leq \lambda_{2,p}(g) \cdots \leq \lambda_{k,p}(g) \leq \cdots \to \infty.$$ 

The case $p = 0$ corresponds to the Laplace-Beltrami operator acting on functions.

The study of the behavior of the eigenvalues of the Laplacian under metric
deformations constitutes one of the main topics in spectral geometry. In particular,
it is of great interest to find situations where the behavior of $\lambda_{k,p}(g)$ for $p \geq 1$
differs completely from that of $\lambda_{k,0}(g)$ (see for instance the situation of collapsing
manifolds described in [2] and [10]).

In what follows, $\lambda_{k,p}$ will be considered as a functional on the space $\mathcal{M}(M)$ of all
Riemannian metrics of volume one on $M$ (the “volume one” condition is a nor-
malization since $\lambda_{k,p}(cg) = \frac{1}{c^2} \lambda_{k,p}(g)$). We will also consider its restriction to a given
conformal class of metrics of fixed volume $[g] = \{g' \in \mathcal{M}(M) \mid g' \text{ is conformal to } g\}$.
There exists an extensive literature dealing with the scalar case \( p = 0 \) (see for instance the introduction of [4] for a synthetic presentation of the main results). In particular, it is well known that,

(i) if \( n = 2 \), then \( \lambda_{k,0} \) is bounded on \( M(M) \). More precisely, if \( M \) is an orientable compact surface of genus \( \gamma \), then there exists a universal constant \( C \) such that \( \forall k \geq 1, \)

\[
\sup_{g \in M(M)} \lambda_{k,0}(g) \leq C(\gamma + 1)k
\]

(see [15] for \( k = 1 \) and [9] for general \( k \)),

(ii) if \( n \geq 3 \), then \( \lambda_{1,0} \) is not bounded on \( M(M) \), that is (see [8]),

\[
\sup_{g \in M(M)} \lambda_{1,0}(g) = \infty,
\]

(iii) \( \forall g \in M(M), \lambda_{k,0} \) is bounded on \( [g] \). Indeed, there exists a constant \( C([g]) \) such that, \( \forall k \geq 1, \)

\[
\sup_{g' \in [g]} \lambda_{k,0}(g') \leq C([g])k^{2/n}
\]

(see [6] for \( k = 1 \) and [11] for general \( k \)).

**Problem.** Do these results still hold when we replace \( \lambda_{k,0} \) with \( \lambda_{k,p}, p \geq 1 \)?

Using the Hodge-de Rham decomposition theorem, one can easily see that for an orientable compact surface, \( \lambda_{k,0}(g) = \lambda_{k,1}(g) = \lambda_{k,2}(g) \). Thus, in dimension 2, the result (i) above is still valid for the eigenvalues of the Laplacian on forms.

The case \( n \geq 3 \) and \( p \geq 1 \) was first considered by Tanno [13] who examined a 1-parameter family of Berger metrics \( (g_t) \), on the sphere \( S^3 \) for which \( \lambda_{1,0}(g_t) \to \infty \) as \( t \to \infty \), and showed that \( \lambda_{1,1}(g_t) \) is bounded. On the other hand, Gentile and Pagliara [7] proved that if \( n \geq 4 \), then for any \( p \in [2, n-2] \), \( \lambda_{1,p} \) is not bounded on \( M(M) \):

\[
\sup_{g \in M(M)} \lambda_{1,p}(g) = \infty.
\]

Hence, the result (ii) above is still valid for \( \lambda_{1,p}, 2 \leq p \leq n-2 \). Note that in the case \( p = 1 \) (and its dual \( p = n-1 \)), the question of whether \( \lambda_{k,1}(g) \) is bounded on \( M(M) \) is still open.

In this paper, we focus, as in result (iii) above, on the restriction of the functional \( \lambda_{k,p} \) to a given conformal class of metrics of fixed volume \( [g] \) on \( M \). As we saw in (iii) above, for any \( k \geq 1 \), \( \lambda_{k,0} \) is bounded on \( [g] \). Since \( d\Delta_{g,0} = \Delta_{g,1} d \), the differential \( df \) of any eigenfunction \( f \) is an eigenform of degree 1 with the same eigenvalue. In particular, we have, \( \forall k \geq 1, \)

\[
\lambda_{k,1}(g) \leq \lambda_{k,0}(g).
\]

Consequently, \( \lambda_{k,1} \) is also bounded on \( [g] \) and the result (iii) is still valid for the eigenvalues of the Laplacian acting on 1-forms. Thanks to the Hodge duality, the same is also true for the eigenvalues of the Laplacian on \( (n-1) \)-forms and on \( n \)-forms. Thus, \( \lambda_{k,p} \) is bounded on \( [g] \) for \( p = 0, 1, n-1 \) and \( n \).

Our main theorem shows that the situation differs drastically for the other values of \( p \). Indeed, it turns out that if \( 2 \leq p \leq n-2 \), then the functional \( \lambda_{1,p} \) is never bounded on \( [g] \), whatever the conformal class \( [g] \) we consider. More precisely, one can conformally deform any metric \( g \) on \( M \) in such a way that the \( n-3 \) eigenvalues \( \lambda_{1,p}, 2 \leq p \leq n-2 \), become simultaneously arbitrarily large.
Theorem 1.1. Let \((M, g)\) be a compact Riemannian manifold of dimension \(n \geq 4\) and let \(A\) be any positive real number. There exists a metric \(g_A\) conformal to \(g\) and having the same volume as \(g\), such that, \(\forall p \in [2, n - 2]\),

\[
\lambda_{1,p}(g_A) \geq A.
\]

In particular, \(\forall p \in [2, n - 2]\), we have

\[
\sup_{g' \in [g]} \lambda_{1,p}(g') = \infty.
\]

Equivalently,

\[
\sup\{\lambda_{1,p}(g') V(g')^{2/n} | g' \text{ conformal to } g\} = \infty,
\]

where \(V(g')\) denotes the volume of the manifold \((M, g')\).

Note that when the supremum is taken over all the metrics of volume 1, then there is no difference between the scalar case \(p = 0\) and the case \(2 \leq p \leq n - 2\) (that is, \(\sup_{g \in M(M)} \lambda_{1,p}(g) = \infty\) as proved in [7].

As an application of Theorem 1.1 and the result of Korevaar (1.3) above, we obtain the following.

Corollary 1.2. Let \((M, g)\) be a compact Riemannian manifold of dimension \(n \geq 4\). For any positive integer \(k\), there exists a metric \(g_k\) conformal to \(g\) such that, \(\forall 2 \leq p \leq n - 2\),

\[
\lambda_{1,p}(g_k) > \lambda_{k,0}(g_k)
\]

and

\[
\lambda_{1,p}(g_k) > \lambda_{k,1}(g_k).
\]

If we set, as in [14], \(\text{Gap}^{0,1}_{k,l}(g) = \lambda_{k,p}(g) - \lambda_{l,q}(g)\), then Corollary 1.2 tells us that, \(\forall k \geq 1\) and \(l \geq 1\), every conformal class of metrics \([g]\) contains metrics \(g'\) satisfying, \(\forall 2 \leq p \leq n - 2\),

\[
\text{Gap}^{0,0}_{k,1}(g') > 0 \quad \text{and} \quad \text{Gap}^{0,1}_{k,l}(g') > 0.
\]

Recall that the gaps \(\text{Gap}^{0,1}_{k,k}(g) = \lambda_{k,0}(g) - \lambda_{k,1}(g)\) between the eigenvalues on functions and those on 1-forms are all nonnegative. An interesting question is to know whether the nature (zero or nonzero) of some of them is imposed by the differential or the conformal structures of the manifold.

Takahashi [14] (see also [8]) proved that any manifold \(M\) of dimension \(n \geq 3\) admits both a metric \(g_1\) with \(\text{Gap}^{0,1}_{1,1}(g_1) = 0\) and a metric \(g_2\) with \(\text{Gap}^{0,1}_{1,1}(g_2) > 0\). Thus, the nature of the first gap is not an invariant of the differential structure of \(M\).

The following result shows that there is no differential or conformal obstruction for any finite number of gaps to be zero. Indeed, we have the following.

Corollary 1.3. Let \((M, g)\) be a compact Riemannian manifold of dimension \(n \geq 4\). For any positive integer \(N\), there exists a metric \(g_N\) conformal to \(g\) such that, \(\forall k \leq N\),

\[
\lambda_{k,1}(g_N) = \lambda_{k,0}(g_N),
\]

that is, the first \(N\) eigenforms of \(\Delta_{g_N}1\) are all exact forms.
This means that, $\forall N \in \mathbb{N}$, any metric $g$ can be conformally deformed to a metric $g_N \in \mathcal{g}$ whose $N$ first gaps vanish, that is,
\[
\text{Gap}_{1,0}^N(g_N) = \cdots = \text{Gap}_{N,N}^0(g_N) = 0.
\]

Finally, we point out that the existence of upper bounds on $\lambda_{1,0}$ under other types of restrictions has been investigated, for instance in [11] and [12]. It would be of course interesting to study the existence of such upper bounds for $\lambda_{1,p}$ with $p \geq 1$.

2. PROOF OF RESULTS

The idea of the proof of Theorem 1.1 consists of showing that the construction of [7] to produce large eigenvalues for forms may be realized by conformal deformations. As in [7], we will use the fact that any manifold is locally almost Euclidean. This implies that we can suppose first that the metric is Euclidean on a small neighbourhood of a point, construct a conformal deformation of the Euclidean metric, and then show that, by quasi-isometry, it gives a conformal deformation of the initial metric with the property we want.

Before going into the proof, let us recall some basic facts about the Laplacian on forms. Indeed, the Hodge-de Rham theorem gives the following orthogonal decomposition of the space $\Lambda^p(M)$ of differential forms of degree $p$ on $M$:
\[
\Lambda^p(M) = \text{Ker} \Delta_{g,p} \oplus d\Lambda^{p-1}(M) \oplus d^*\Lambda^{p+1}(M).
\]

The operator $\Delta_{g,p}$ leaves this decomposition invariant. Hence, if we denote by $\{\lambda'_{k,p}(g) : k \geq 1\}$ the eigenvalues of $\Delta_{g,p}$ acting on the subspace $d\Lambda^{p-1}(M)$ of exact $p$-forms, and by $\{\lambda''_{k,p}(g) : k \geq 1\}$ those corresponding to the subspace $d^*\Lambda^{p+1}(M)$ of co-exact $p$-forms, then $\{\lambda_{k,p}(g) : k \geq 1\}$ is equal to the re-ordered union of $\{\lambda'_{k,p}(g) : k \geq 1\}$ and $\{\lambda''_{k,p}(g) : k \geq 1\}$:
\[
\{\lambda_{k,p}(g) : k \geq 1\} = \{\lambda'_{k,p}(g) : k \geq 1\} \cup \{\lambda''_{k,p}(g) : k \geq 1\}.
\]

Since $d$ and $d^*$ commute with the Laplacian, we have
\[
\lambda'_{k,p}(g) = \lambda''_{k-1,p}(g)
\]
and then,
\[
\{\lambda_{k,p}(g) : k \geq 1\} = \{\lambda'_{k,p}(g) : k \geq 1\} \cup \{\lambda''_{k-1,p}(g) : k \geq 1\}.
\]

Proof of Corollary 1.2. For $p = 1$ we have, $\forall k \geq 1$, $\lambda_{k,1}(g) = \lambda_{k,0}(g)$ and then
\[
\{\lambda_{k,1}(g) : k \geq 1\} = \{\lambda_{k,0}(g) : k \geq 1\} \cup \{\lambda'_{k,2}(g) : k \geq 1\}.
\]

Applying Theorem 1.1 and Korevaar's inequality [13], we get, for any positive integer $N$, the existence of a metric $g_N$ satisfying
\[
\lambda'_{1,2}(g_N) > C(|g|)N^{\frac{2}{n}} \geq \lambda_{N,0}(g_N).
\]

The result of the corollary follows immediately.

Proof of Theorem 1.1. Recall first the idea of the proof in [7]: they start with the manifold $M$, make a hole and glue what they call a cigar, that is, the union of a standard half-sphere with a cylinder $[0,L] \times S^{n-1}$, since a cigar is diffeomorphic to a ball, the resulting manifold is diffeomorphic to $M$. Then, they endow $M$ with a
metric $g$, so that it induces the standard metric on the cigar and show that, as $L \to \infty$, $\lambda_{1,p}(g_L)$ is uniformly bounded below by a positive constant for $2 \leq p \leq n - 2$. They conclude by noting that the volume of $(M, g_L)$ goes to infinity with $L$ (indeed, the volume one metric $\tilde{g}_L = V(g_L)^{-\frac{2}{n}}g_L$ satisfies $\lambda_{1,p}(\tilde{g}_L) = \lambda_{1,p}(g_L)V(g_L)^{\frac{2}{n}} \to \infty$ as $L \to \infty$).

First, let us show that the cigar may be realized as a conformal deformation of the $n$-dimensional Euclidean unit ball $B^n$. Indeed, the Euclidean metric $g_{euc}$ has the following expression in polar coordinates:

$$g_{euc} = dr^2 + r^2d\sigma^2,$$

where $0 < r < 1$ and $d\sigma^2$ denotes the standard metric of the $(n-1)$-sphere $S^{n-1}$. For any positive real number $L$, we multiply this metric by the following positive function $f_L$ of the parameter $r$:

$$f_L(r) = \begin{cases} \frac{4e^{2L}}{[(1+r^2)^{\frac{2}{n}}]^2} & \text{if } 0 \leq r \leq e^{-L}, \\ \frac{1}{r^2} & \text{if } e^{-L} \leq r \leq 1. \end{cases}$$

The resulting metric $f_Lg_{euc}$ on $B^n$ is so that the part $\{(r \leq e^{-L}), f_Lg_{euc}\}$ is isometric to $(B^n, \frac{4}{(1+r^2)^{\frac{2}{n}}}(dr^2 + r^2d\sigma^2))$ that may be identified, via a stereographic projection, with the standard half-sphere (of radius 1), while the part $\{e^{-L} < r < 1\}$ endowed with the metric $f_Lg_{euc} = (\frac{dr}{r})^2 + d\sigma^2$, is isometric to the standard cylinder $[0,L] \times S^{n-1}$ with the product metric. Hence, the ball $(B^n, f_Lg_{euc})$ is isometric to a standard cigar $C_L$ of length $L$.

Note that the function $f_L$ is only of class $C^1$, but, using classical density results, it is possible to smooth it in order to get a smooth metric $f_Lg_{euc}$ conformal to $g_{euc}$ and quasi-isometric to $f_Lg_{euc}$ with a quasi-isometry ratio arbitrarily close to 1.

As in [4], we will need the two following remarks (see [4, Remark O1 and Lemma 2.3(i), p. 343]):

(i) if two Riemannian metrics $g_1, g_2$ on a manifold $M$ are $\alpha$-quasi-isometric, then for any smooth positive function $f$, the conformal metrics $fg_1$ and $fg_2$ are also $\alpha$-quasi-isometric,

(ii) if $(M, g)$ is a compact Riemannian manifold and $x_0 \in M$, then for any positive $\delta$, there exists a Riemannian metric $g_\delta$ on $M$ which is flat in a neighborhood of $x_0$ and $(1+\delta)$-quasi-isometric to $g$ (that is, $\forall v \in TM, (1+\delta)^{-2}g_\delta(v,v) \leq g(v,v) \leq (1+\delta)^2g_\delta(v,v)$).

Now, let us fix a Riemannian metric $g$ on $M$ and a positive real number $\delta \in (0,1)$. Thanks to the previous remark (ii), there exists a metric $g_\delta$ on $M$ which is flat in a neighborhood of a point $x_0 \in M$ and $(1+\delta)$-quasi-isometric to $g$. Up to a dilatation, we can suppose that this neighborhood contains a Euclidean ball of radius 2 centered at $x_0$. On the ball of radius 1, $B(x_0,1)$, we make the conformal change described above in order to get a cigar $C_L$ of length $L$. On the annulus $\{1 \leq r \leq 2\}$, we interpolate by considering the conformal metric given in polar coordinates by $h(r)(dr^2 + r^2d\sigma^2)$, where $h$ is any smooth function, $\frac{1}{3} \leq h(r) \leq 1$, satisfying

$$h(r) = \begin{cases} \frac{1}{r^2} & \text{if } 1 \leq r \leq \frac{4}{3}, \\ 1 & \text{if } \frac{4}{3} \leq r \leq 2. \end{cases}$$
Hence, we get, ∀L > 0, a smooth metric \( g_{\delta,L} \) on \( M \) conformal to \( g_\delta \) and such that a neighborhood of the point \( x_0 \) is isometric to a standard cigar \( C_L \) of length \( L \). In particular, \( (M,g_{\delta,L}) \) contains a regular domain \( \Omega_L \) naturally identified with the cylinder \([0,L] \times S^{n-1} \). Moreover, the rest of the manifold \( (M\backslash\Omega_L,g_{\delta,L}) \) does not depend on \( L \) (up to an isometry). Using arguments as in [7] and [11], it is possible to compare the first eigenvalue \( \lambda'_1(g_{\delta,L}) \) of the Laplacian \( \Delta_{g_{\delta,L}} \) acting on exact \( p \)-forms on \( M \) with the first positive eigenvalue \( \mu_{1,p}(\Omega_L) \) of \( \Delta_{g_{\delta,L}} \) acting on exact \( p \)-forms on the domain \( \Omega_L \) under absolute boundary conditions. Indeed, there exist three positive constants \( a, b \) and \( c \), independent of \( L \), such that (see [7, Lemma 1])

\[
\lambda'_1(g_{\delta,L}) \geq \frac{a}{\mu_{1,p}(\Omega_L)} + b + c.
\]

On the other hand, recall that for any integer \( p \in [1,n-2] \), the Laplacian acting on \( p \)-forms on the standard sphere \( S^{n-1} \) admits no zero eigenvalues. Hence, \( \forall p \in [2,n-2] \), we have

\[
\mu_{1,p}(\Omega_L) = \min_{\mu_{1,p}(S^{n-1})} \{ \mu_{1,0}(0,L \times S^{n-1}) \}
\]

\[
\geq \min \{ \mu_{1,0}([0,L]) + \lambda_{1,1}(S^{n-1}), \mu_{1,1}([0,L]) + \lambda_{1,p-1}(S^{n-1}) \}
\]

\[
\geq \min \{ \lambda_{1,p}(S^{n-1}), \lambda_{1,p-1}(S^{n-1}) \}
\]

\[
\geq \min_{1 \leq q \leq n-2} \lambda_{1,q}(S^{n-1}).
\]

Therefore, there exists a positive constant \( C \), independent of \( L \), such that, \( \forall p \in [2,n-2] \) and \( \forall L > 0 \), we have

\[
\lambda'_1(g_{\delta,L}) \geq C.
\]

The volume one metric \( g_{\delta,L} = V(g_{\delta,L})^{1\over 2} g_{\delta,L} \) satisfies, \( \forall p \in [2,n-2] \),

\[
(2.3) \quad \lambda'_1(g_{\delta,L}) \geq CV(g_{\delta,L})^{1\over 2} \geq KL^{1\over 2}
\]

for some positive constant \( K \).

Let us denote by \( \phi_L \), \( \forall L > 0 \), the conformal ratio between \( g_{\delta,L} \) and \( g_\delta \), that is, \( g_{\delta,L} = \phi_L g_\delta \). The metric \( g_L = \phi_L g_\delta \) is then conformal to \( g_\delta \) and \((1+\delta)\)-quasisymmetric to \( g_{\delta,L} \) (see remark (i) above). The volume of \( g_L \) is bounded below by \((1+\delta)^{-n}V(g_{\delta,L}) = (1+\delta)^{-n}V(g_{\delta,L}) \) while its first eigenvalue on exact \( p \)-forms satisfies \( \lambda'_1(g_L) \geq (1+\delta)^{-2(n+2p+1)}\lambda'_1(g_{\delta,L}) \) (see [5, Proposition 3.3, p. 441]). Hence, for any \( p \in [2,n-2] \), we have

\[
(2.4) \quad \lambda'_1(g_L)V(g_L)^{1\over 2} \geq KL^{1\over 2}
\]

for some positive constant \( K \).

Now, recall that (see relation (2.1) above), for any \( p \leq n \),

\[
\lambda_{1,p}(g_L) = \min \{ \lambda'_{1,p}(g_L), \lambda''_{1,p}(g_L) \}.
\]

On the other hand, the Hodge star operator \( * \) commutes with the Laplacian, and identify the space of co-exact \( p \)-forms with the space of exact \( (n-p) \)-forms (that is, \( *d^*\Lambda^p(M) = d\Lambda^{n-p}(M) \)). It follows that, \( \forall p \leq n \), \( \lambda''_{1,p}(g_L) = \lambda'_{1,n-p}(g_L) \). Therefore, using (2.4) above, we have \( \forall L \geq 4 \) and \( \forall p \in [2,n-2] \),

\[
\lambda_{1,p}(g_L)V(g_L)^{1\over 2} = \min \{ \lambda'_{1,p}(g_L), \lambda'_{1,n-p}(g_L) \} V(g_L)^{1\over 2} \geq KL^{1\over 2}
\]

and then, \( \lambda_{1,p}(g_L)V(g_L)^{1\over 2} \to \infty \) as \( L \to \infty \). Theorem 1.1 follows immediately. \( \square \)
