An adaptive splitting algorithm for the sum of two generalized monotone operators and one cocoercive operator

Minh N. Dao and Hung M. Phan

Abstract

Splitting algorithms for finding a zero of sum of operators often involve multiple steps which are referred to as forward or backward steps. Forward steps are the explicit use of the operators and backward steps involve the operators implicitly via their resolvents. In this paper, we study an adaptive splitting algorithm for finding a zero of the sum of three operators. We assume that two of the operators are generalized monotone and their resolvents are computable, while the other operator is cocoercive but its resolvent is missing or costly to compute. Our splitting algorithm adapts new parameters to the generalized monotonicity of the operators and, at the same time, combines appropriate forward and backward steps to guarantee convergence to a solution of the problem.

Keywords: Adaptive Douglas–Rachford algorithm; Conically averaged operator; Fixed point iterations; Forward-backward algorithm; Three-operator splitting

1 Introduction

Operator splitting algorithms are developed for structured optimization problems based on the idea of performing the computation separately on individual operators. At each iteration, they require multiple steps which are known as either forward or backward steps. The forward steps are almost always easy as they use the operator directly. The backward steps, on the other hand, are often more complicated as they use the resolvents of the operators. While there are many operators whose resolvents are readily computable, there exist operators whose resolvents may not be computable in closed form, thus, it is necessary to use the forward steps in certain situations. Notable examples of splitting algorithms include the forward-backward algorithm [15], the Douglas–Rachford algorithm [14, 15], and many others.

In this paper, we study an adaptive splitting algorithm for the inclusion problem

\[
\text{find } x \in X \text{ such that } 0 \in Ax + Bx + Cx,
\]
where $X$ is a real Hilbert space, $A,B: X \rightrightarrows X$ are generalized monotone operators, and $C: X \to X$ is a cocoercive operator. It is worth mentioning that the problem of finding a zero of the sum of finitely many maximally monotone operators and a cocoercive operator can be written as a special instance of (1), where $A$ is a maximally monotone operator and $B$ is the normal cone of a closed subspace [16, 17]. This was in turn solved by the so-called forward-Douglas–Rachford splitting algorithm [8, 16]. In [13], a three-operator splitting algorithm was proposed to address (1) assuming $A$ and $B$ to be only maximally monotone.

In [11], an adaptive Douglas–Rachford splitting algorithm was introduced for the case when $A$ and $B$ are strongly and weakly monotone operators, and $C = 0$. Therein, adaptive parameters were used to accommodate the corresponding monotonicity properties. This approach was later studied in [4] by means of conical averagedness.

Motivated by the two approaches in [11] and [13], this paper is devoted to develop an adaptive splitting algorithm for solving (1) when $A$ and $B$ are strongly and weakly monotone operators and $C$ is a cocoercive operator. We utilize new parameters so that the generated sequence converges weakly to a fixed point, while the corresponding image sequence converges weakly via the resolvent (the shadow sequence) converges weakly to a solution of the original problem. If the strong monotonicity outweighs the weak monotonicity, the convergence of the shadow sequence is strong. In addition, we recover some contemporary results for the Douglas–Rachford algorithm, forward-backward algorithm, and also backward-forward algorithm which has recently been studied in [1]. On the one hand, our new algorithm enhances the framework of [13] to allow for handling generalized monotone operators. On the other hand, it extends the adaptive approach in [11] to incorporate the third operator that is cocoercive and whose resolvent might not be explicitly computable. An application to minimizing the sum of three functions is also included.

On another note, it is well known that the alternating direction method of multipliers (ADMM) can be written as the Douglas–Rachford algorithm in dual settings. Recently, this important relation has been extended in [3] for the adaptive framework, namely, a new adaptive ADMM can be written as the adaptive Douglas–Rachford algorithm in dual settings. We refer interested readers to [3] for a rather comprehensive discussion on the ADMM.

The remainder of the paper is organized as follows. In Sect. 2, we present our adaptive splitting algorithm and recall some preliminary materials. Section 3 provides an abstract convergence result, which will be used to derive the main results in Sect. 4. In Sect. 5, we revisit some convergence results for the case of two operators based on the newly developed framework. Finally, Sect. 6 presents an immediate application of the main results to minimizing the sum of three functions.

2 The algorithm

Throughout, $X$ is a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and induced norm $\| \cdot \|$. The set of nonnegative integers is denoted by $\mathbb{N}$ and the set of real numbers is denoted by $\mathbb{R}$. We denote the set of nonnegative real numbers by $\mathbb{R}_+: = \{ x \in \mathbb{R} | x \geq 0 \}$ and the set of the positive real numbers by $\mathbb{R}_+^*: = \{ x \in \mathbb{R} | x > 0 \}$. The notation $A: X \rightrightarrows X$ is to indicate that $A$ is a set-valued operator on $X$ and the notation $A: X \to X$ is to indicate that $A$ is a single-valued operator on $X$.

Let $A: X \rightrightarrows X$ be an operator on $X$. Then its domain is $\text{dom} \ A := \{ x \in X | Ax \neq \emptyset \}$, its set of zeros is $\text{zer} \ A := \{ x \in X | 0 \in Ax \}$, and its set of fixed points is $\text{Fix} \ A := \{ x \in X | x \in Ax \}$.
The graph of $A$ is the set $\text{gra} A := \{(x, u) \in X \times X \mid u \in Ax\}$ and the inverse of $A$, denoted by $A^{-1}$, is the operator with graph $\text{gra} A^{-1} := \{(u, x) \in X \times X \mid u \in Ax\}$. The resolvent of $A$ is defined by

$$J_A := (\text{Id} + A)^{-1},$$

(2)

where $\text{Id}$ is the identity operator.

Now, let $\eta, \gamma, \delta \in \mathbb{R}^+$, and set $\lambda := 1 + \frac{\delta}{\gamma}$. In order to address problem (1), we employ the operator

$$T_{A,B,C} := \text{Id} - \eta J_{\gamma A} + \eta J_{\gamma B} ((1 - \lambda)\text{Id} + \gamma Ba - \delta C\gamma a).$$

(3)

We will also refer to $\gamma$ and $\delta$ as the resolvent parameters as they are used to scale the operators $A, B$ in their respective resolvents. In fact, we adapt $\gamma$ and $\delta$ to the generalized monotonicity of $A$ and $B$ in order to guarantee the convergence of $T_{A,B,C}$. Intuitively, in the case $A$ and $B$ are maximally monotone, one would expect the use of equal resolvent parameters $\gamma = \delta$, and in other cases, $\gamma$ and $\delta$ are no longer the same. This phenomenon was initially observed in [11, 12]. Although the imbalance of monotonicity can be resolved by shifting the identity between the operators as in [11, Remark 4.15], our plan is to conduct the convergence analysis of the algorithm applied to the original operators.

To motivate the use of (3), the following result shows the relationship between the fixed point set of $T_{A,B,C}$ and the solution set of (1).

**Proposition 2.1** (fixed points of $T_{A,B,C}$) Let $T_{A,B,C}$ be defined by (3). Then $\text{Fix} T_{A,B,C} \neq \emptyset$ if and only if $\text{zer}(A + B + C) \neq \emptyset$. Moreover, if $J_{\gamma A}$ is single-valued, then

$$J_{\gamma A}(\text{Fix} T_{A,B,C}) = \text{zer}(A + B + C).$$

(4)

**Proof** Let $x \in \text{dom} T_{A,B,C}$. We have

$$T_{A,B,C} x = \{x - \eta a + \eta J_{\gamma B}(1 - \lambda)\gamma a - (\lambda - 1)\gamma Ca \mid a \in J_{\gamma A}a\}. $$

(5)

Therefore,

$$x \in \text{Fix} T_{A,B,C} \iff \exists a \in J_{\gamma A}a, \quad a \in J_{(\lambda - 1)\gamma B}(1 - \lambda)x + \lambda a - (\lambda - 1)\gamma Ca) \quad (6a)$$

$$\iff \exists a \in J_{\gamma A}a, \quad (1 - \lambda)x + \lambda a - (\lambda - 1)\gamma Ca - a \in (\lambda - 1)\gamma Ba \quad (6b)$$

$$\iff \exists a \in X, \quad x - a \in \gamma Aa \quad \text{and} \quad a - x \in Ba + Ca \quad (6c)$$

$$\iff \exists a \in J_{\gamma A} \cap \text{zer}(A + B + C) \quad (6d)$$

which completes the proof.

In the rest of this section, we recall some preliminary concepts and results. Let $T : X \to X$ be a single-valued operator on $X$. Then $T$ is nonexpansive if it is Lipschitz continuous
with constant 1 on its domain, i.e.,

$$\forall x, y \in \text{dom } T, \quad \|Tx - Ty\| \leq \|x - y\|. \quad (7)$$

The operator $T$ is said to be conically averaged with constant $\theta \in \mathbb{R}_{++}$ (see [4, 7]) if there exists a nonexpansive operator $N : X \to X$ such that

$$T = (1 - \theta) \text{Id} + \theta N. \quad (8)$$

Given a conically $\theta$-averaged operator, it is $\theta$-averaged when $\theta \in ]0, 1[$ and nonexpansive when $\theta = 1$. Further properties are discussed in the following result from [4, Proposition 2.2].

**Proposition 2.2** Let $T : X \to X$, $\theta \in \mathbb{R}_{++}$, and $\lambda \in \mathbb{R}_{++}$. Then the following are equivalent:

(i) $T$ is conically $\theta$-averaged.

(ii) $(1 - \lambda) \text{Id} + \lambda T$ is conically $\lambda \theta$-averaged.

(iii) For all $x, y \in \text{dom } T$,

$$\|Tx - Ty\|^2 \leq \|x - y\|^2 - \frac{1}{\theta} \left\| (\text{Id} - T)x - (\text{Id} - T)y \right\|^2. \quad (9)$$

Recall from [11] that an operator $A : X \rightrightarrows X$ is $\alpha$-monotone for some $\alpha \in \mathbb{R}$ if

$$\forall (x, u), (y, v) \in \text{gra } A, \quad \langle x - y, u - v \rangle \geq \alpha \|x - y\|^2. \quad (10)$$

We say that $A$ is monotone if $\alpha = 0$, strongly monotone if $\alpha > 0$, and weakly monotone if $\alpha < 0$. The operator $A$ is said to be maximally $\alpha$-monotone if it is $\alpha$-monotone and there is no $\alpha$-monotone operator $B : X \rightrightarrows X$ such that $\text{gra } B$ properly contains $\text{gra } A$.

We say that $A$ is $\sigma$-cocoercive if $\sigma \in \mathbb{R}_{++}$ and

$$\forall (x, u), (y, v) \in \text{gra } A, \quad \langle x - y, u - v \rangle \geq \sigma \|u - v\|^2. \quad (11)$$

Clearly, if $A$ is $\sigma$-cocoercive, then $A$ is single-valued and monotone. In fact, $\sigma$-cocoercivity was extended to $\sigma$-comonotonicity to allow for negative parameter $\sigma$, see [4, 7] for more details. Next, we recall a result from [11, Lemma 3.3 and Proposition 3.4].

**Proposition 2.3** (single-valued and full domain) Let $A : X \rightrightarrows X$ be $\alpha$-monotone and let $\gamma \in \mathbb{R}_{++}$ such that $1 + \gamma \alpha > 0$. Then the following hold:

(i) $J_{\gamma A}$ is single-valued and $(1 + \gamma \alpha)$-cocoercive.

(ii) $\text{dom } J_{\gamma A} = X$ if and only if $A$ is maximally $\alpha$-monotone.

Finally, we recall the demiclosedness principle for cocoercive operators developed in [2]. A fundamental result in the theory of nonexpansive mapping is Browder’s celebrated demiclosedness principle [9]. It was extended for finitely many firmly nonexpansive mappings in [5] and was later generalized in [2] for a finite family of conically averaged mappings or for a finite family of cocoercive mappings. An instant application of the demiclosedness principle is to provide a simple proof for the weak convergence of the shadow
sequence of the Douglas–Rachford algorithm [5] and of the adaptive Douglas–Rachford algorithm [2]. For our analysis, we recall only the result for two operators.

**Proposition 2.4** (demiclosedness principle for balanced cocoercive operators) Let $T_1 : X \to X$ and $T_2 : X \to X$ be respectively $\sigma_1$- and $\sigma_2$-cocoercive, let $(x_n)_{n \in \mathbb{N}}$ and $(z_n)_{n \in \mathbb{N}}$ be sequences in $X$, and let $\rho_1, \rho_2 \in \mathbb{R}^+$ be such that

$$\frac{\rho_1 \sigma_1 + \rho_2 \sigma_2}{\rho_1 + \rho_2} \geq 1.$$  
(12)

Suppose that as $n \to +\infty$,

$$x_n \rightharpoonup x^*, \quad z_n \rightharpoonup z^*,$$  
(13a)

$$T_1 x_n \rightharpoonup y^*, \quad T_2 z_n \rightharpoonup y^*,$$  
(13b)

$$\rho_1 (x_n - T_1 x_n) + \rho_2 (z_n - T_2 z_n) \to \rho_1 (x^* - y^*) + \rho_2 (z^* - y^*),$$  
(13c)

$$T_1 x_n - T_2 z_n \to 0.$$  
(13d)

Then $y^* = T_1 x^* = T_2 z^*$.

**Proof** Apply [2, Theorem 3.2] for two operators. \qed

### 3 An abstract convergence result

In order to study $T_{A,B,C}$, it is reasonable to consider the general operator

$$T := \text{Id} - \eta T_1 + \eta T_2(-\nu \text{Id} + \lambda T_1 - \delta T_3 T_1),$$  
(14)

where $T_1, T_2, T_3 : X \to X$ and $\eta, \nu, \lambda, \delta \in \mathbb{R}^+$. In this section, we establish a convergence result for the operator $T$ under the cocoercivity of $T_1, T_2, T_3$. We begin with a useful technical lemma.

**Lemma 3.1** Let $a, b, c, d$ be in $X$ and let $\eta, \nu, \lambda, \delta$ be in $\mathbb{R}^+$. Set $e := -\nu a + \lambda b - \delta c$ and $f := a - \eta b + \eta d$. Then, for all $\sigma \in \mathbb{R}^+$,

$$\|f\|^2 = \|a\|^2 - \left(\frac{\lambda}{\eta \nu} - \frac{\delta}{2 \nu \nu \sigma} - 1\right)\|a - f\|^2 - \frac{\delta}{2 \nu \nu \sigma} \|a - f - 2 \eta \sigma e\|^2 + \frac{\lambda \eta}{\nu} \|b\|^2 + \frac{\lambda \eta}{\nu} \|d\|^2 - 2 \eta \langle a, b \rangle - 2 \eta \langle e, d \rangle - \frac{2 \delta \eta}{\nu} \langle c, b \rangle - \sigma \|c\|^2.$$  
(15)

**Proof** By assumption, $a - f = \eta (b - d)$ and $\lambda b = \nu a + \delta c + e$, which imply that

$$\frac{\lambda}{\eta^2} \|a - f\|^2 = \lambda \|b - d\|^2$$  
(16a)

$$= \lambda \|b\|^2 + \lambda \|d\|^2 - 2 \lambda \langle b, d \rangle$$  
(16b)

$$= \lambda \|b\|^2 + \lambda \|d\|^2 - 2 \nu \langle a, b \rangle - 2 \delta \langle c, d \rangle$$  
(16c)

$$= \lambda \|b\|^2 + \lambda \|d\|^2 - 2 \nu \langle a, d \rangle - 2 \delta \langle c, d \rangle - 2 \langle e, d \rangle.$$  
(16d)
Writing $d = b - \frac{1}{\eta}(a - f)$, we have that

$$-2\nu (a, d) = -2\nu (a, b) + \frac{2\nu}{\eta} (a, a - f) = -2\nu (a, b) + \frac{\nu}{\eta} (\|a\|^2 + \|a - f\|^2 - \|f\|^2)$$  \hfill (17)

and that

$$-2\delta (c, d) = -2\delta (c, b) + \frac{2\delta}{\eta} (c, a - f)$$ \hfill (18a)

$$= -2\delta ((c, b) - \sigma \|c\|^2) - 2\delta \sigma \|c\|^2 + \frac{2\delta}{\eta} (c, a - f)$$ \hfill (18b)

$$= -2\delta ((c, b) - \sigma \|c\|^2) - \frac{\delta}{2\eta\sigma} \|a - f - 2\eta \sigma c\|^2 + \frac{\delta}{2\eta\sigma} \|a - f\|^2.$$ \hfill (18c)

Substituting (17) and (18a)–(18c) into (16d) yields

$$\frac{\nu}{\eta} \|f\|^2 = \frac{\nu}{\eta} \|a\|^2 - \left(\frac{\lambda}{\eta^2} - \frac{\delta}{2\eta^2 \sigma} - \frac{\nu}{\eta}\right) \|a - f\|^2 - \frac{\delta}{2\eta^2 \sigma} \|a - f - 2\eta \sigma c\|^2 + \lambda \|b\|^2 + \lambda \|d\|^2 - 2\nu (a, b) - 2(e, d) - 2\delta ((c, b) - \sigma \|c\|^2),$$ \hfill (19)

which implies the conclusion. □

The following proposition is inspired by [13, Proposition 2.1].

**Proposition 3.2** Let $T_1$, $T_2$, and $T_3$ be respectively $\sigma_1$, $\sigma_2$, and $\sigma_3$-cocoercive. Let $\eta, \nu, \lambda, \delta \in \mathbb{R}^{++}$ and define

$$T := \text{Id} - \eta T_1 + \eta T_2 (-\nu \text{Id} + \lambda T_1 - \delta T_3 T_1).$$ \hfill (20)

Then the following hold:

(i) If $\lambda = 2\nu \sigma_1 = 2\sigma_2$ and

$$\eta^* := \frac{1}{\nu} \left(\lambda - \frac{\delta}{2\sigma_3}\right) > 0,$$ \hfill (21)

then, for all $x, y \in \text{dom } T$,

$$\|Tx - Ty\|^2 \leq \|x - y\|^2 - \left(\frac{\eta^*}{\eta} - 1\right) \|(\text{Id} - T)x - (\text{Id} - T)y\|^2 - \frac{\delta}{2\eta \nu \sigma_3} \|(\text{Id} - T)x - (\text{Id} - T)y - 2\eta \sigma_3 (T_3 T_1 x - T_3 T_1 y)\|^2.$$ \hfill (22)

(ii) If $\lambda < \nu \sigma_1 + \sigma_2$ and

$$\eta^* := \frac{1}{\nu} \left(\frac{2\nu \sigma_1 - \lambda)(2\sigma_2 - \lambda) - \lambda - \frac{\delta}{2\sigma_3}\right) > 0,$$ \hfill (23)

then, for all $x, y \in \text{dom } T$,

$$\|Tx - Ty\|^2 \leq \|x - y\|^2 - \left(\frac{\eta^*}{\eta} - 1\right) \|(\text{Id} - T)x - (\text{Id} - T)y\|^2.$$
\[ \frac{\delta}{2\eta \nu \sigma_3} \| (\text{Id} - T)x - (\text{Id} - T)y - 2\eta \sigma_3 (T_3 T_1 x - T_3 T_1 y) \|^2 \]
\[ - \frac{\eta}{2\nu (\sigma_1 + \sigma_2 - \lambda)} \times \| (2\nu \sigma_1 - \lambda)(T_1 x - T_1 y) + (2\sigma_2 - \lambda)(T_2 S x - T_2 S y) \|^2, \]

(24)

where \( S := -\nu \text{Id} + \lambda T_1 - \delta T_3 T_1 \).

In both cases, \( T \) is conically \( \frac{\rho}{\nu} \)-averaged.

**Proof** Let \( x, y \in X \) be arbitrary and set \( S := -\nu \text{Id} + \lambda T_1 - \delta T_3 T_1 \). Then \( T = \text{Id} - \eta T_1 + \eta T_2 S \).

Define

\[ a := x - y, \quad b := T_1 x - T_1 y, \]
\[ c := T_3 T_1 x - T_3 T_1 y, \quad d := T_2 S x - T_2 S y, \]
\[ e := S x - S y, \quad f := T x - T y. \]

Then \( e = -\nu a + \lambda b - \delta c \) and \( f = a - \eta b + \eta d \). By applying Lemma 3.1 (with \( \sigma = \sigma_3 \)),

\[ \| f \|^2 = \| a \|^2 - \left( \frac{\lambda}{\eta \nu} - \frac{\delta}{2\eta \nu \sigma_3} - 1 \right) \| a - f \|^2 - \frac{\delta}{2\eta \nu \sigma_3} \| a - f - 2\eta \sigma c \|^2 \]
\[ + \frac{\lambda \eta}{\nu} \| b \|^2 + \frac{\lambda \eta}{\nu} \| d \|^2 - 2\eta \langle a, b \rangle - 2\frac{\eta}{\nu} \langle e, d \rangle - \frac{2\delta \eta}{\nu} \langle (c, b) - \sigma_3 \| e \|^2 \rangle. \]

(26)

On the other hand, the cocoercivity of \( T_1, T_2, \) and \( T_3 \) yields

\[ \langle a, b \rangle \geq \sigma_1 \| b \|^2, \quad \langle e, d \rangle \geq \sigma_2 \| d \|^2, \quad \langle b, c \rangle \geq \sigma_3 \| c \|^2. \]

(27)

Combining this with (26), we obtain that

\[ \| f \|^2 \leq \| a \|^2 - \left( \frac{\lambda}{\eta \nu} - \frac{\delta}{2\eta \nu \sigma_3} - 1 \right) \| a - f \|^2 - \frac{\delta}{2\eta \nu \sigma_3} \| a - f - 2\sigma_3 c \|^2 \]
\[ - \frac{\eta}{\nu} (2\nu \sigma_1 - \lambda) \| b \|^2 - \frac{\eta}{\nu} (2\sigma_2 - \lambda) \| d \|^2. \]

(28)

(i): Since \( \lambda = 2\nu \sigma_1 = 2\sigma_2 \), (28) reduces to

\[ \| f \|^2 \leq \| a \|^2 - \left( \frac{\eta^*}{\eta} - 1 \right) \| a - f \|^2 - \frac{\delta}{2\eta \nu \sigma_3} \| a - f - 2\sigma_3 c \|^2, \]

(29)

which gives (22).

(ii): Set \( \kappa := 2\nu \sigma_1 - \lambda \) and \( \mu := 2\sigma_2 - \lambda \). Then \( \kappa + \mu = 2(\nu \sigma_1 + \sigma_2 - \lambda) > 0 \) and

\[ (2\nu \sigma_1 - \lambda) \| b \|^2 + (2\sigma_2 - \lambda) \| d \|^2 \]
\[ = \kappa \| b \|^2 + \mu \| d \|^2 \]
\[ = \frac{1}{\kappa + \mu} \| \kappa b + \mu d \|^2 + \frac{\kappa \mu}{\kappa + \mu} \| b - d \|^2 \]

(30a)

(30b)
\[
\begin{align*}
\frac{1}{2(\nu \sigma_1 + \sigma_2 - \lambda)} \left\| (2\nu \sigma_1 - \lambda)b + (2\sigma_2 - \lambda)d \right\|^2 \\
+ \frac{(2\nu \sigma_1 - \lambda)(2\sigma_2 - \lambda)}{2\eta^2(\nu \sigma_1 + \sigma_2 - \lambda)} \left\| a - f \right\|^2,
\end{align*}
\]  

which proves (24).

Finally, in both cases (i) and (ii), we have that

\[
\|Tx - Ty\|^2 \leq \|x - y\|^2 - \left( \frac{\eta^*}{\eta} - 1 \right) \left\| (I - T)x - (I - T)y \right\|^2,
\]

which implies that $T$ is conically $\frac{\eta}{\eta^*}$-averaged due to Proposition 2.2(i) and (iii). \qed

In what follows, we say that $(x_n)_{n \in \mathbb{N}}$ is a sequence generated by $T$ if, for all $n \in \mathbb{N}$, $x_{n+1} \in Tx_n$.

**Theorem 3.3** (abstract convergence) Let $T_1$, $T_2$, and $T_3$ be respectively $\sigma_1$-, $\sigma_2$-, and $\sigma_3$-cocoercive. Let $\eta, \nu, \lambda, \delta \in \mathbb{R}_+$, and define

\[
T := I - \eta T_1 + \eta T_2(-\nu I + \lambda T_1 - \delta T_3 T_1).
\]

Suppose that Fix $T \neq \emptyset$ and that either

(a) $\lambda = 2\nu \sigma_1 = 2\sigma_2$, and $\eta < \eta^* := \frac{1}{\nu}(\lambda - \frac{1}{2\sigma_2})$; or

(b) $\lambda < \nu \sigma_1 + \sigma_2$ and $\eta < \eta^* := \frac{1}{\nu}(\frac{2(2\nu \sigma_1 - \lambda)(2\sigma_2 - \lambda)}{2(\nu \sigma_1 + \sigma_2 - \lambda)} + \lambda - \frac{\delta}{2\sigma_2})$.

Let $(x_n)_{n \in \mathbb{N}} \subset \text{dom } T$ be a sequence generated by $T$ and set $S := -\nu I + \lambda T_1 - \delta T_3 T_1$. Then the following hold:

(i) $T$ is $\frac{\eta}{\eta^*}$-averaged. Consequently, $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x^* \in \text{Fix } T$ and the rate of asymptotic regularity of $T$ is $o(1/\sqrt{n})$, i.e., $\|x_n - Tx_n\| = o(1/\sqrt{n})$.

(ii) $(T_3 T_1 x_n)_{n \in \mathbb{N}}$ converges strongly to $T_3 T_1 x^*$ and $T_3 T_1 (\text{Fix } T) = \{T_3 T_1 x^*\}$.

(iii) If (a) holds and $\nu = \lambda - 1$, then $(T_1 x_n)_{n \in \mathbb{N}}$ and $(T_2 S x_n)_{n \in \mathbb{N}}$ converge weakly to $T_1 x^* = T_2 S x^*$.

(iv) If (b) holds, then $(T_1 x_n)_{n \in \mathbb{N}}$ and $(T_2 S x_n)_{n \in \mathbb{N}}$ converge strongly to $T_1 x^* = T_2 S x^*$ and $T_1 \text{Fix } T = T_2 S \text{Fix } T = \{T_1 x^*\}$.

**Proof** Set $\omega_1 := \frac{\eta^*}{\eta} - 1$, $\omega_2 := \frac{\delta}{2\sigma_2 \eta^*}$, and

\[
\omega_3 := \begin{cases} 
0 & \text{if } \lambda = 2\nu \sigma_1 = 2\sigma_2, \\
\frac{\eta}{2\nu(\nu \sigma_1 + \sigma_2 - \lambda)} & \text{if } \lambda < \nu \sigma_1 + \sigma_2.
\end{cases}
\]  

(34)
Then \(\omega_1 > 0, \omega_2 > 0,\) and \(\omega_3 \geq 0\). We derive from Proposition 3.2 that, for all \(x, y \in \text{dom } T\),

\[
\|Tx - Ty\|^2 \leq \|x - y\|^2 - \omega_1 \|(\text{Id} - T)x - (\text{Id} - T)y\|^2
\]
\[
- \omega_2 \|(\text{Id} - T)x - (\text{Id} - T)y - 2\eta \sigma_3 (T_3 T_1 x - T_3 T_1 y)\|^2
\]
\[
- \omega_3 \|(2\nu \sigma_1 - \lambda)(T_1 x - T_1 y) + (2\sigma_2 - \lambda)(T_2 Sx - T_2 Sy)\|^2
\] (35)

and \(T\) is conically \(\frac{\eta}{\nu}\)-averaged.

(i): Since \(\eta < \eta^*, T\) is \(\frac{\eta}{\nu}\)-averaged. By [4, Corollary 2.10], \((x_n)_{n\in\mathbb{N}}\) converges weakly to a point \(x^* \in \text{Fix } T\) and the rate of asymptotic regularity of \(T\) is \(o(1/\sqrt{n})\).

(ii): Let \(y \in \text{Fix } T\). It follows from (35) that, for all \(n \in \mathbb{N}\),

\[
\|x_{n+1} - y\|^2 \leq \|x_n - y\|^2 - \omega_1 \|(\text{Id} - T)x_n\|^2
\]
\[
- \omega_2 \|(\text{Id} - T)x_n - 2\eta \sigma_3 (T_3 T_1 x_n - T_3 T_1 y)\|^2
\]
\[
- \omega_3 \|(2\nu \sigma_1 - \lambda)(T_1 x_n - T_1 y) + (2\sigma_2 - \lambda)(T_2 Sx_n - T_2 Sy)\|^2.
\] (36)

Telescoping this inequality yields

\[
\omega_1 \sum_{n=0}^{\infty} \|(\text{Id} - T)x_n\|^2 + \omega_2 \sum_{n=0}^{\infty} \|(\text{Id} - T)x_n - 2\eta \sigma_3 (T_3 T_1 x_n - T_3 T_1 y)\|^2
\]
\[
+ \omega_3 \sum_{n=0}^{\infty} \|(2\nu \sigma_1 - \lambda)(T_1 x_n - T_1 y) + (2\sigma_2 - \lambda)(T_2 Sx_n - T_2 Sy)\|^2
\]
\[
\leq \|x_0 - y\|^2 < +\infty.
\] (37)

Since \(\omega_1, \omega_2 > 0\) and \(\omega_3 \geq 0\), we deduce that, as \(n \to +\infty\),

\[(\text{Id} - T)x_n \to 0 \quad \text{and} \quad (\text{Id} - T)x_n - 2\eta \sigma_3 (T_3 T_1 x_n - T_3 T_1 y) \to 0,
\] (38)

which imply that

\[T_3 T_1 x_n \to T_3 T_1 y.\] (39)

As \(y\) is arbitrary in \(\text{Fix } T\) and the limit of \(T_3 T_1 x_n\) is unique, we must have that \(T_3 T_1\) is a constant on \(\text{Fix } T\). It follows that \(T_3 T_1(\text{Fix } T) = \{T_3 T_1 x^*\}\).

(iii): We will apply the demiclosedness principle in Proposition 2.4 to prove that \((T_1 x_n)_{n\in\mathbb{N}}\) converges weakly to \(T_1 x^*\). First, recall from (i) that

\(x_n \to x^* \in \text{Fix } T.\) (40)

As a result, \((x_n)_{n\in\mathbb{N}}\) is bounded, and so is \((T_1 x_n)_{n\in\mathbb{N}}\). Let \(y^*\) be a weak cluster point of \((T_1 x_n)_{n\in\mathbb{N}}\). Then there exists a subsequence \((x_{n_k})_{k\in\mathbb{N}}\) such that

\[T_1 x_{n_k} \to y^*.\] (41)
Define $z_n := Sx_n = (1 - \lambda)x_n + \lambda T_1 x_n - \delta T_3 T_1 x_n$. Since $T_3 T_1 x_n \to T_3 T_1 x^*$ by (ii), it follows that

$$z_{k_n} \rightharpoonup (1 - \lambda)x^* + \lambda y^* - \delta T_3 T_1 x^* =: z^*.$$ (42)

Next, we have from (i) that

$$T_1 x_{k_n} - T_2 z_{k_n} = (T_1 - T_2 S)x_{k_n} = \frac{1}{\eta} (\text{Id} - T)x_{k_n} \to 0,$$ (43)

which, due to (41), implies that

$$T_2 z_{k_n} \rightharpoonup y^*.$$ (44)

Set $\rho_1 := \lambda - 1 = \nu > 0$ and $\rho_2 := 1$. Then

$$\frac{\rho_1 \sigma_1 + \rho_2 \sigma_2}{\rho_1 + \rho_2} = \frac{(\lambda - 1) \frac{\lambda}{\nu} + 1 \cdot \frac{\lambda}{\nu}}{\lambda} = 1$$ (45)

and it follows from (42) that

$$\rho_1(x^* - y^*) + \rho_2(z^* - y^*) = -\delta T_3 T_1 x^*.$$ (46)

Using the definition of $z_n$ and then (43), we obtain

$$\rho_1(x_{k_n} - T_1 x_{k_n}) + \rho_2(z_{k_n} - T_2 z_{k_n})$$

$$= (\lambda - 1)(x_{k_n} - T_1 x_{k_n}) + (1 - \lambda) x_{k_n} + \lambda T_1 x_{k_n} - \delta T_3 T_1 x_{k_n} - T_2 z_{k_n}$$

$$= T_1 x_{k_n} - T_2 z_{k_n} - \delta T_3 T_1 x_{k_n}$$

$$\to -\delta T_3 T_1 x^* = \rho_1(x^* - y^*) + \rho_2(z^* - T_2 z^*).$$ (47)

Now, in view of (40), (41), (42), (43), (44), (45), and (47), we apply Proposition 2.4 to derive that

$$y^* = T_1 x^* = T_2 z^*,$$ (48)

which is the unique weak cluster point of $(T_1 x_n)_{n \in \mathbb{N}}$. Thus, $T_1 x_n \rightharpoonup T_1 x^*$. Since $T_1 x_n - T_2 S x_n = \frac{1}{\eta} (\text{Id} - T)x_n \to 0$ and $x^* \in \text{Fix } T$, we derive that $T_2 S x_n \rightharpoonup T_1 x^* = T_2 S x^*$.

(iv): In this case, $\omega_3 > 0$. So (37) implies that, as $n \to +\infty$,

$$(2 \nu \sigma_1 - \lambda)(T_1 x_n - T_1 y) + (2 \sigma_2 - \lambda)(T_2 S x_n - T_2 S y) \to 0.$$ (49)

On the other hand,

$$(T_1 x_n - T_1 y) - (T_2 S x_n - T_2 S y) = \frac{1}{\eta} (\text{Id} - T)x_n - \frac{1}{\eta} (\text{Id} - T)y = \frac{1}{\eta} (\text{Id} - T)x_n \to 0,$$ (50)
which together with (49) yields

\[ T_1x_n \to T_1y \quad \text{and} \quad T_2Sx_n \to T_2Sy. \] (51)

Since \( y \) is arbitrary in Fix \( T \) and \( x^* \in \text{Fix} \ T \), it also follows that \( T_1y = T_1x^* \) and \( T_2Sy = T_2Sx^* = T_1x^* \). Hence, \( T_1(\text{Fix} \ T) = T_2S(\text{Fix} \ T) = \{T_1x^*\} \). The proof is complete. \( \square \)

4 Zeros of the sum of three operators

In this section, we apply the result to the problem of finding a zero of the sum of three operators. We assume that the operator \( A \) is maximally \( \alpha \)-monotone, the operator \( B \) is maximally \( \beta \)-monotone, and the operator \( C \) is \( \sigma \)-cocoercive. We will consider two cases: \( \alpha + \beta = 0 \) and \( \alpha + \beta > 0 \).

**Theorem 4.1** (convergence in the case \( \alpha + \beta = 0 \)) Suppose that \( A \) and \( B \) are respectively maximally \( \alpha \)- and \( \beta \)-monotone with \( \alpha + \beta = 0 \), and \( C \) is \( \sigma \)-cocoercive. Let \( \eta \in \mathbb{R}_{++} \) and let \( \gamma \in \mathbb{R}_{++} \) be such that

\[ 1 + 2\gamma \alpha > 0 \quad \text{and} \quad \eta^* := 2 + 2\gamma \alpha - \frac{\gamma}{2\sigma} > 0. \] (52)

Set \( \delta = \frac{\gamma}{2\sigma}, \lambda = 1 + \frac{1}{2\gamma}, \) and let \( (x_n)_{n \in \mathbb{N}} \) be a sequence generated by \( T_{A,B,C} \) in (3). Then the following hold:

(i) \( T_{A,B,C} \) is single-valued and has full domain.

(ii) For all \( x,y \in X \),

\[
\begin{align*}
\|T_{A,B,C}x - T_{A,B,C}y\|^2 \\
&\leq \|x - y\|^2 - \left(\frac{\eta^*}{\eta} - 1\right)\|(I - T_{A,B,C})x - (I - T_{A,B,C})y\|^2 \\
&\quad - \frac{\gamma}{2\eta \sigma} \|(I - T_{A,B,C})x - (I - T_{A,B,C})y - 2\eta \sigma (C\gamma A x - C\gamma A y)\|^2.
\end{align*}
\] (53)

In particular, \( T_{A,B,C} \) is conically \( \frac{\eta}{\eta^*} \)-averaged.

(iii) If \( \text{zer}(A + B + C) \neq \emptyset \) and \( \eta < \eta^* \), then the rate of asymptotic regularity of \( T_{A,B,C} \) is \( o(1/\sqrt{n}) \) and \( (x_n)_{n \in \mathbb{N}} \) converges weakly to a point \( x^* \in \text{Fix} \ T \), while \( (I_{J_{\gamma}A} x_n)_{n \in \mathbb{N}} \) and \( (J_{\lambda B} S x_n)_{n \in \mathbb{N}} \) converge weakly to \( I_{J\gamma A} x^* = I_{J\lambda B} S x^* \in \text{zer}(A + B + C) \) where

\[ S := (1 - \lambda)I_{J\gamma A} - \delta C_{J\gamma A} \quad \text{and} \quad (C_{J\gamma A} x_n)_{n \in \mathbb{N}} \text{ converges strongly to } C_{J\gamma A} x^* \]

Proof First, we can check that there always exists \( \gamma \in \mathbb{R}_{++} \), such that (52) holds (indeed, by choosing \( \gamma > 0 \) satisfying \( 1/\gamma > \max\{-2\alpha, -\alpha + 1/(4\sigma)\} \)). Next, we have that \( 1 + \gamma \alpha = 1/2 + (1 + 2\gamma \alpha)/2 > 0 \). Since \( \alpha + \beta = 0 \), we also have

\[ 1 + \delta \beta = 1 - \delta \alpha = 1 - \frac{\gamma \alpha}{1 + 2\gamma \alpha} = \frac{1 + \gamma \alpha}{1 + 2\gamma \alpha} > 0. \] (54)

By Proposition 2.3, \( J\gamma A, J\lambda B \), and hence \( T_{A,B,C} \) are single-valued and have full domain. This proves (i).
Next, Proposition 2.3 also implies that $I_{fA}$ and $I_{fB}$ are respectively $(1 + γα)$- and $(1 + δβ)$- cocoercive. Set $σ_1 := 1 + γα > 0$, $σ_2 := 1 + δβ > 0$, $σ_3 := σ > 0$, and $ν := λ − 1 > 0$. Then $2νσ_1 = 2(λ − 1)(1 + γα) = 2(1 + γα)/(1 + 2γα) = λ$ and, by (54), $2σ_2 = 2(1 + δβ) = 2(1 + γα)/(1 + 2γα) = λ$. Also,\\n
\[
\frac{1}{ν} \left( \frac{λ − δ}{2σ_3} \right) = \frac{1}{λ − 1} \left( λ − \frac{(λ − 1)γ}{2σ} \right) = 1 + γ − \frac{γ}{δ} = γ^∗ > 0. \tag{55}
\]

Applying Proposition 3.2(i), we get (ii).

Now, by Proposition 2.1, $I_{fA}(\text{Fix } T_{A,B,C}) = \text{zer}(A + B + C)$. We then apply Theorem 3.3(i)–(iii) to complete the proof.

Using Theorem 4.1, we recover the results in [13, Theorem 2.1(1)], which partly spurred our interest in the topic.

**Corollary 4.2** Suppose that $A$ and $B$ are respectively maximally monotone, that $C$ is $γ$- cocoercive. Let $γ ∈ [0,4σ]$, $η ∈ [0,2−\frac{γ}{δ}]$, and define

\[
T_{A,B,C} := \text{Id} − ηI_{fA} + ηI_{fB}(2I_{fA} − \text{Id} − γC_{fA}). \tag{56}
\]

Then the following hold:

(i) $T_{A,B,C}$ is $\frac{2σ}{4σ−γ}$-averaged.

(ii) If $\text{zer}(A + B + C) \neq \emptyset$, then the rate of asymptotic regularity of $T_{A,B,C}$ is $o(1/\sqrt{n})$ and $(x_n)_{n ∈ N}$ converges weakly to a point $x^* ∈ \text{Fix } T$, while $(I_{fA}x_n)_{n ∈ N}$ and $(I_{fB}(2I_{fA} − \text{Id} − γC_{fA})x_n)_{n ∈ N}$ converge weakly to $I_{fA}x^* = I_{fB}(2I_{fA} − \text{Id} − γC_{fA})x^* ∈ \text{zer}(A + B + C)$, $(C_{fA}x_n)_{n ∈ N}$ converges strongly to $C_{fA}x^*$, and $C(\text{zer}(A + B + C)) = \{C_{fA}x^*\}$.

**Proof** Apply Theorem 4.1 with $α = β = 0$, $δ = γ$, and $η^∗ = 2 − \frac{γ}{δ}$.

**Remark 4.3** (range of parameter $γ$) We note that while Corollary 4.2(ii) is straightforward from [13, Proposition 2.1], Corollary 4.2(ii) improves upon [13, Theorem 2.1(1)] by only requiring the parameter $γ ∈ [0,4σ]$ instead of $γ ∈ [0,2σε]$ with $ε ∈ [0,1]$.

Next, we consider the case $α + β > 0$. This case indeed allows for some flexibility in choosing the resolvent parameters $γ$, $δ$. In particular, let us recall the case $α + β = 0$ in Theorem 4.1, the resolvent parameters $γ$, $δ$ must be directly related by

\[
δ = \frac{γ}{1 + 2γα}, \quad \text{or equivalently,} \quad \frac{1}{δ} = \frac{1}{γ} + 2α. \tag{57}
\]

In the case $α + β > 0$, the above exact relation is no longer necessary; instead, for given $γ$, one can choose $δ$ within a range such that

\[
\max \left\{ 0, \frac{1}{γ} + 2α − 2\sqrt{Δ} \right\} < \frac{1}{δ} < \frac{1}{γ} + 2α + 2\sqrt{Δ} \tag{58}
\]

for some positive $Δ$ that depends on $α$, $β$, and $γ$. In the next results, we will show that such choices for $(γ, δ)$ always exist and will guarantee convergence of the algorithm.
Lemma 4.4 (existence of resolvent parameters) Let $\alpha, \beta \in \mathbb{R}$ be such that $\alpha + \beta > 0$, let $\sigma \in \mathbb{R}_{++}$, and let $\gamma, \delta \in \mathbb{R}_{++}$. Set

$$
\gamma_0 := \begin{cases} 
0 & \text{if } \alpha \geq \frac{1}{4\sigma}, \\
-\alpha + \frac{1}{4\sigma} & \text{if } -\frac{1}{4\sigma} < \alpha < \frac{1}{4\sigma}, \\
2\beta - 2\sqrt{(\alpha + \beta)(\beta - \frac{1}{4\sigma})} & \text{if } \alpha < -\frac{1}{4\sigma}.
\end{cases}
$$

(59)

Then $\gamma_0 \geq \max\{0, -\alpha + \frac{1}{4\sigma}\}$ and the following statements are equivalent:

(i) $\frac{4\gamma\delta(1 + \gamma\alpha)(1 + \delta\beta) - (\gamma + \delta)^2}{2\gamma\delta^2(\alpha + \beta)} - \frac{\gamma}{2\sigma} > 0$.

(ii) $\frac{1}{\gamma} > \gamma_0$ and $\max\{0, \frac{1}{\gamma} + 2\alpha - 2\sqrt{\Delta}\} < \frac{1}{\gamma} < \frac{1}{\gamma} + 2\alpha + 2\sqrt{\Delta}$, where

$$
\Delta := (\alpha + \beta)(\frac{1}{\gamma} + \alpha - \frac{1}{4\sigma}).
$$

Consequently, there always exist $\gamma, \delta \in \mathbb{R}_{++}$ that satisfy both (i) and (iii).

Proof If $\alpha \geq -\frac{1}{4\sigma}$, then $\gamma_0 = \max\{0, -\alpha + \frac{1}{4\sigma}\}$ by definition. If $\alpha < -\frac{1}{4\sigma} < 0$, then $\beta - \frac{1}{4\sigma} > \beta + \alpha > 0$ and

$$
\gamma_0 = 2\beta - 2\sqrt{(\alpha + \beta)(\beta - \frac{1}{4\sigma})} = \left(\sqrt{\beta - \frac{1}{4\sigma} - \sqrt{\alpha + \beta}}\right)^2 - \alpha + \frac{1}{4\sigma} > 0
$$

(60a)

$$
\geq -\alpha + \frac{1}{4\sigma} = \max\{0, -\alpha + \frac{1}{4\sigma}\}.
$$

(60b)

Next, we have that

$$
\frac{4\gamma\delta(1 + \gamma\alpha)(1 + \delta\beta) - (\gamma + \delta)^2}{2\gamma\delta^2(\alpha + \beta)} - \frac{\gamma}{2\sigma} > 0
$$

(61a)

$$
\iff (\gamma + \delta)^2 < 4\gamma\delta(1 + \gamma\alpha)(1 + \delta\beta) - \frac{\gamma^2\delta^2(\alpha + \beta)}{\sigma}
$$

(61b)

$$
\iff \left(1 - 4\gamma\beta - 4\gamma^2\alpha\beta + \frac{\gamma^2\delta^2(\alpha + \beta)}{\sigma}\right)\delta^2 - 2\gamma(1 + 2\gamma\alpha)\delta + \gamma^2 < 0
$$

(61c)

$$
\iff \left(\frac{1}{\gamma^2} - 4\gamma - 4\gamma\alpha + \frac{\alpha + \beta}{\delta}\right) - 2\left(\frac{1}{\gamma} + 2\alpha\right)\frac{1}{\delta} + \frac{1}{\delta^2} < 0
$$

(61d)

$$
\iff \Delta = (\alpha + \beta)(\frac{1}{\gamma} + \alpha - \frac{1}{4\sigma}) > 0
$$

and

$$
\frac{1}{\gamma} + 2\alpha - 2\sqrt{\Delta} < \frac{1}{\gamma} < \frac{1}{\gamma} + 2\alpha + 2\sqrt{\Delta}
$$

(61e)

$$
\iff \frac{1}{\gamma} > -\alpha + \frac{1}{4\sigma} \quad \text{and} \quad \frac{1}{\gamma} + 2\alpha - 2\sqrt{\Delta} < \frac{1}{\gamma} < \frac{1}{\gamma} + 2\alpha + 2\sqrt{\Delta}.
$$

(61f)

Suppose (ii) holds, then $\frac{1}{\gamma} > \gamma_0 \geq \max\{0, -\alpha + \frac{1}{4\sigma}\}$. So (61f) holds. It follows that (61a) holds, which is (i).

Now, suppose that (i) holds. Then (61f) holds, and so $\frac{1}{\gamma} > \max\{0, -\alpha + \frac{1}{4\sigma}\}$ and $\frac{1}{\gamma} + 2\alpha + 2\sqrt{\Delta} > 0$. To obtain (ii), it suffices to show that $\frac{1}{\gamma} > \gamma_0$. If $\alpha \geq -\frac{1}{4\sigma}$, then $\gamma_0 = \max\{0, -\alpha + \frac{1}{4\sigma}\}$, and we readily have $\frac{1}{\gamma} > \gamma_0$. Let us consider the case when $\alpha < -\frac{1}{4\sigma}$. Then $\beta - \frac{1}{4\sigma} >$
\( \beta + \alpha > 0 \) and
\[
\frac{1}{\gamma} + 2\alpha + 2\sqrt{\Delta} > 0 \quad \iff \quad \left( \sqrt{\alpha + \beta} + \sqrt{\frac{1}{\gamma} + \alpha - \frac{1}{4\sigma}} \right)^2 > \beta - \frac{1}{4\sigma} \quad (62a)
\]
\[
\iff \quad \sqrt{\frac{1}{\gamma} + \alpha - \frac{1}{4\sigma}} > \sqrt{\beta - \frac{1}{4\sigma}} - \sqrt{\alpha + \beta} \quad (62b)
\]
\[
\iff \quad \frac{1}{\gamma} + \alpha - \frac{1}{4\sigma} > \left( \sqrt{\beta - \frac{1}{4\sigma}} - \sqrt{\alpha + \beta} \right)^2 \quad (62c)
\]
\[
\iff \quad \frac{1}{\gamma} > 2\beta - 2(\alpha + \beta)\left( \beta - \frac{1}{4\sigma} \right) = \eta_0, \quad (62d)
\]
which finish our claim.

To see the existence of \( \gamma \) and \( \delta \), we choose \( \gamma > 0 \) such that \( \frac{1}{\gamma} > \eta_0 \) and then choose \( \delta > 0 \) that satisfies the second condition in (ii).

We are now ready to prove the convergence of the algorithm for the case \( \alpha + \beta > 0 \).

**Theorem 4.5** (convergence in the case \( \alpha + \beta > 0 \)) Suppose that \( A \) and \( B \) are respectively maximally \( \alpha \)- and \( \beta \)-monotone with \( \alpha + \beta > 0 \), that \( C \) is \( \sigma \)-cocoercive, and that \( \gamma, \delta \in \mathbb{R}^+ \), satisfy
\[
\eta^* := \frac{4\gamma \delta(1 + \gamma \alpha)(1 + \delta \beta) - (\gamma + \delta)^2}{2\gamma \delta^2(\alpha + \beta)} - \frac{\sqrt{\gamma}}{2\sigma} > 0. \quad (63)
\]
Set \( \lambda = 1 + \frac{\gamma}{\delta} \) and let \( \eta \in \mathbb{R}^+ \). Let \( (x_n)_{n \in \mathbb{N}} \) be a sequence generated by \( T_{A,B,C} \) in (3) and set \( S := (1 - \lambda)I + \lambda J_A - \delta C J_A \). Then the following hold:

(i) \( T_{A,B,C} \) is single-valued and has full domain.

(ii) For all \( x, y \in X \),
\[
\|T_{A,B,C}x - T_{A,B,C}y\|^2 \leq \|x - y\|^2 - \left( \frac{\eta^*}{\eta} - 1 \right) \| (I - T_{A,B,C})x - (I - T_{A,B,C})y \|^2
\]
\[
- \frac{\sqrt{\gamma}}{2\eta \sigma} \left\| (I - T_{A,B,C})x - (I - T_{A,B,C})y - 2\eta \sigma (C J_A x - C J_A y) \right\|^2
\]
\[
- \frac{\sqrt{\gamma} \eta}{2\delta^2(\alpha + \beta)} \times \left( (\lambda - 2 + 2\delta \alpha)(T_1 x - T_1 y) + (2 - \lambda + 2\delta \beta)(T_2 S x - T_2 S y) \right)^2. \quad (64)
\]

In particular, \( T_{A,B,C} \) is conically \( \frac{\eta}{\sigma} \)-averaged.

(iii) If \( \text{zer}(A + B + C) \neq \emptyset \) and \( \eta < \eta^* \), then the rate of asymptotic regularity of \( T_{A,B,C} \) is \( o(1/\sqrt{n}) \) and \( (x_n)_{n \in \mathbb{N}} \) converges weakly to a point \( x^* \in \text{Fix } T \), while \( (J_{1A} x_n)_{n \in \mathbb{N}} \) and \( (J_{1B} S x_n)_{n \in \mathbb{N}} \) converge strongly to \( J_{1A} x^* = J_{1B} S x^* \in \text{zer}(A + B + C) \), \( (C J_{1A} x_n)_{n \in \mathbb{N}} \) converges strongly to \( C J_{1A} x^* \), and \( \text{zer}(A + B + C) = (J_{1A} x^*) \).

**Proof** First, Lemma 4.4 ensures the existence of \( \gamma, \delta \in \mathbb{R}^+ \), satisfying (63). In view of (63), it also follows from Lemma 4.4 that \( 1/\gamma > -\alpha + 1/4\sigma \), and so \( 1 + \gamma \alpha > \gamma/(4\sigma) > 0 \), which
together with (63) implies that $1 + \delta \beta > 0$. In turn, Proposition 2.3 implies that $J_{\gamma A}, J_{\delta B}$, and hence $T_{A,B,C}$ are single-valued and have full domain, and we get (i).

We also derive from Proposition 2.3 that $J_{\gamma A}$ and $J_{\delta B}$ are $(1 + \gamma \alpha)$- and $(1 + \delta \beta)$-cocoercive, respectively. Now, set $\sigma_1 := 1 + \gamma \alpha > 0$, $\sigma_2 := 1 + \delta \beta > 0$, and $\sigma_3 := \sigma > 0$, and $\nu := \lambda - 1 > 0$. On the one hand, since $\alpha + \beta > 0$,

$$\nu \sigma_1 + \sigma_2 = (\lambda - 1)(1 + \gamma \alpha) + (1 + \delta \beta) = \lambda + \delta (\alpha + \beta) > \lambda.$$  

(65)

On the other hand,

$$\frac{1}{\nu} \left( \frac{(2 \nu \sigma_1 - \lambda)(2 \sigma_2 - \lambda)}{2(\nu \sigma_1 + \sigma_2 - \lambda)} + \frac{\lambda - \delta}{2 \sigma_3} \right)$$

$$= \frac{1}{\nu} \left( \frac{4 \nu \sigma_1 \sigma_2 - \lambda^2}{2(\nu \sigma_1 + \sigma_2 - \lambda)} - \frac{\delta}{2 \sigma_3} \right)$$

(66a)

$$= \frac{\gamma}{\delta} \left( \frac{4 \gamma \delta (1 + \gamma \alpha)(1 + \delta \beta) - (\gamma + \delta)^2}{2 \gamma^2 \delta (\alpha + \beta)} - \frac{\delta}{2 \sigma} \right)$$

(66b)

$$= \frac{4 \gamma \delta (1 + \gamma \alpha)(1 + \delta \beta) - (\gamma + \delta)^2}{2 \gamma^2 \delta (\alpha + \beta)} - \frac{\gamma}{2 \sigma} = \eta^* > 0.$$  

(66c)

Therefore, we obtain (ii) due to Proposition 3.2(ii).

Finally, applying Theorem 3.3(i), (ii), and (iv) and noting that $J_{\gamma A}(\text{Fix } T_{A,B,C}) = \text{zer}(A + B + C)$ due to Proposition 2.1, we complete the proof.

□

5 Zeros of the sum of two operators

The new results in Theorems 4.1 and 4.5 allow us to revisit the relaxed forward-backward, relaxed backward-forward, and adaptive Douglas–Rachford algorithms for finding a zero of the sum of two operators.

Theorem 5.1 (relaxed forward-backward) Suppose that $B$ is maximally $\beta$-monotone with $\beta \in \mathbb{R}_+$, and that $C$ is $\sigma$-cocoercive. Let $\gamma \in ]0,4\sigma[$, $\eta \in ]0,2 - \frac{\gamma}{4\sigma}[$, and let $(x_n)_{n \in \mathbb{N}}$ be a sequence generated by

$$T_{FB} := (1 - \eta)I + \eta J_{\gamma B}(I - \gamma C).$$

(67)

Then the following hold:

(i) For all $x, y \in X$,

$$\|T_{FB}x - T_{FB}y\|^2 \leq \|x - y\|^2 - \left( \frac{4 \sigma - \gamma}{2 \eta \sigma} - 1 \right) \| (I - T_{FB})x - (I - T_{FB})y \|^2$$

$$- \frac{\gamma}{2 \eta \sigma} \| (I - T_{FB})x - (I - T_{FB})y - 2 \eta \sigma (Cx - Cy) \|^2.$$  

(68)

In particular, $T_{FB}$ is $\frac{2 \sigma}{4 \sigma - \gamma}$-averaged.

(ii) If $\text{zer}(B + C) \neq \emptyset$, then the rate of asymptotic regularity of $T_{FB}$ is $o(1/\sqrt{n})$ and $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x^* \in \text{zer}(B + C)$, while $(C_{\sigma})_{n \in \mathbb{N}}$ converges strongly to $Cx^*$, and $C(\text{zer}(B + C)) = \{Cx^*\}$. Moreover, if additionally $\beta > 0$, then $(x_n)_{n \in \mathbb{N}}$ converges strongly to $x^*$ and $\text{zer}(B + C) = \{x^*\}$. 

Proof. Apply Theorems 4.1 and 4.5 with $A = 0$, $\alpha = 0$, $\lambda = 2$, and $\delta = \gamma$. \hfill \Box

**Theorem 5.2** (relaxed backward-forward) Suppose that $A$ is maximally $\alpha$-monotone with $\alpha \in \mathbb{R}_+$, and that $C$ is $\sigma$-cocoercive. Let $\gamma \in ]0, 4\sigma [, \ \eta \in ]0, 2 \frac{\gamma}{2\sigma} [$, and let $(x_n)_{n \in \mathbb{N}}$ be a sequence generated by

$$T_{BF} := (1 - \eta)Id + \eta(Id - \gamma C)J_{\gamma A}.$$  \hfill (69)

Then the following hold:

(i) For all $x,y \in X$,

$$\|T_{BF}x - T_{BF}y\|^2 \leq \|x - y\|^2 - \left(\frac{4\sigma - \gamma}{2\eta\sigma} - 1\right)\|(Id - T_{BF})x - (Id - T_{BF})y\|^2 - \frac{\gamma}{2\eta\sigma}\|(Id - T_{BF})x - (Id - T_{BF})y - 2\eta\sigma(Cx - Cy)\|^2. \hfill (70)$$

In particular, $T_{BF}$ is $\frac{2\eta\sigma}{2\sigma - \gamma}$-averaged.

(ii) If $\text{zer}(A + C) \neq \emptyset$, then the rate of asymptotic regularity of $T_{BF}$ is $o(1/\sqrt{n})$ and $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x^* \in \text{Fix}T_{BF}$, while $(J_{\gamma A}x_n)_{n \in \mathbb{N}}$ converges weakly to $J_{\gamma A}x^* \in \text{zer}(A + C)$, $(Cx_n)_{n \in \mathbb{N}}$ converges strongly to $Cx^*$, and $C(\text{zer}(A + C)) = \{Cx^*\}$. Moreover, if additionally $\alpha > 0$, then $(J_{\gamma A}x_n)_{n \in \mathbb{N}}$ converges strongly to $J_{\gamma A}x^* \in \text{zer}(A + C)$.

Proof. Apply Theorems 4.1 and 4.5 with $B = 0$, $\beta = 0$, $\lambda = 2$, and $\delta = \gamma$. \hfill \Box

**Theorem 5.3** (adaptive DR) Suppose that $A$ and $B$ are respectively maximally $\alpha$- and $\beta$-monotone, that either

(a) $\alpha + \beta = 0$, $1 + 2\gamma\alpha > 0$, $\delta = \frac{\gamma}{1 + 2\gamma\alpha}, \ \eta^* = 2$; or

(b) $\alpha + \beta > 0$, $\eta^* := \frac{4\gamma(1 + \gamma)(1 + \beta)(1 + 2\gamma\alpha + \gamma\delta)}{2\eta\gamma + (\alpha + \beta)} > 0$.

Let $\lambda = 1 + \frac{\lambda}{\gamma}, \ \eta \in ]0, \eta^*[,$ and let $(x_n)_{n \in \mathbb{N}}$ be a sequence generated by

$$T_{DR} := Id - \eta J_{\gamma A} + \eta J_{\gamma B}(1 - \lambda)Id + \lambda J_{\gamma A}.$$  \hfill (71)

Set $S := (1 - \lambda)Id + \lambda J_{\gamma A}$. Then the following hold:

(i) $T_{DR}$ is $\frac{\eta}{\gamma}$-averaged and has full domain.

(ii) If $\text{zer}(A + B) \neq \emptyset$, then the rate of asymptotic regularity of $T_{DR}$ is $o(1/\sqrt{n})$ and $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x^* \in \text{Fix}T$ with $J_{\gamma A}x^* \in \text{zer}(A + B)$. Moreover, when (a) holds, $(J_{\gamma A}x_n)_{n \in \mathbb{N}}$ and $(J_{\gamma B}Sx_n)_{n \in \mathbb{N}}$ converge weakly to $J_{\gamma A}x^* = J_{\gamma B}Sx^*$; when (b) holds, $(J_{\gamma A}x_n)_{n \in \mathbb{N}}$ and $(J_{\gamma B}Sx_n)_{n \in \mathbb{N}}$ converge strongly to $J_{\gamma A}x^* = J_{\gamma B}Sx^*$ and $\text{zer}(A + B) = \{J_{\gamma A}x^*\}$.

Proof. Apply Theorems 4.1 and 4.5 with $C = 0$ and note that the operator $C$ is $\sigma$-cocoercive with any $\sigma > 0$. \hfill \Box

**Remark 5.4** In terms of the range of parameter $\gamma$, Theorems 5.1 and 5.2 only require $\gamma \in ]0, 2\beta[,$ improving the classical convergence results for the forward-backward and backward-forward algorithms which require $\gamma \in ]0, 2\beta[,$ see, e.g., [1, Corollaries 3.4 and
3.6]. On the other hand, as $T_{DR}$ in (71) is actually the adaptive DR operator (see [11, Lemma 4.1(ii)]), Theorem 5.3 unifies [11, Theorem 4.5], [4, Theorem 5.7], and [2, Theorem 4.1].

6 Minimizing the sum of three functions
In this section, we consider the problem of minimizing the sum of three functions. Let $f : X \to ]-\infty, +\infty[$. Then $f$ is proper if $\text{dom} f := \{x \in X \mid f(x) < +\infty\} \neq \emptyset$, and lower semicontinuous if $\forall x \in X, f(x) \leq \lim_{z \to x} f(z)$. Given $x, y \in X$, the function $f$ is $\alpha$-convex if

$$f((1-\kappa)x + \kappa y) + \frac{\alpha}{2}\kappa(1-\kappa)\|x-y\|^2 \leq (1-\kappa)f(x) + \kappa f(y).$$

We simply say $f$ is convex if $\alpha = 0$. We also say that $f$ is strongly convex or weakly convex, if $\alpha > 0$ or $\alpha < 0$, respectively.

Next, let $f : X \to ]-\infty, +\infty[$ be proper. The Fréchet subdifferential of $f$ at $x$ is defined by

$$\hat{\partial}f(x) := \{u \in X \mid \liminf_{z \to x} \frac{f(z) - f(x) - \langle u, z-x \rangle}{\|z-x\|} \geq 0\}. \quad (73)$$

The proximity operator of $f$ with parameter $\gamma \in \mathbb{R}^{++}$ is the mapping $\text{Prox}_{\gamma f} : X \mapsto X$ defined by

$$\forall x \in X, \quad \text{Prox}_{\gamma f}(x) := \arg\min_{z \in X} \left( f(z) + \frac{1}{2\gamma}\|z-x\|^2 \right). \quad (74)$$

We refer to [10] for a list of proximity operators of common convex functions. For an $\alpha$-convex function, the relationship between its Fréchet subdifferential and its proximity operator is described in the following lemma.

Lemma 6.1 (proximity operators of $\alpha$-convex functions) Let $f : X \to ]-\infty, +\infty[$ be a proper, lower semicontinuous and $\alpha$-convex function. Let $\gamma \in \mathbb{R}^{++}$ be such that $1 + \gamma\alpha > 0$. Then

(i) $\hat{\partial}f$ is maximally $\alpha$-monotone.
(ii) $\text{Prox}_{\gamma f} = I_f\hat{\partial}f$ is single-valued and has full domain.

Proof See [11, Lemma 5.2].

Now, we assume that $f, g : X \to ]-\infty, +\infty[$ are proper lower semicontinuous, and respectively $\alpha$- and $\beta$-convex functions, and $h : X \to \mathbb{R}$ is a differentiable convex function with Lipschitz continuous gradient. We will solve the minimization problem

$$\min_{x \in X} f(x) + g(x) + h(x) \quad (75)$$

by employing the operator

$$T_{f,g,h} := \text{Id} - \eta\text{Prox}_{\gamma f} + \eta\text{Prox}_{\delta g}((1-\lambda)\text{Id} + \lambda\text{Prox}_{\gamma f} - \delta \nabla h\text{Prox}_{\gamma f}) \quad (76)$$

with appropriately chosen parameters $\gamma, \delta, \lambda, \eta \in \mathbb{R}^{++}$.
Theorem 6.2 (minimizing the sum of three functions) Let $f, g: X \to ]-\infty, +\infty]$ be proper lower semicontinuous functions, and let $h: X \to \mathbb{R}$ be a differentiable convex function whose gradient is Lipschitz continuous with constant $1/\sigma$. Suppose that $f$ and $g$ are $\alpha$-convex and $\beta$-convex, respectively, and that either

(a) $\alpha + \beta = 0, \quad 1 + 2\nu \alpha > 0, \quad \delta = \frac{\nu}{1 + 2\nu}, \quad \eta^* := 2 + 2\nu\alpha - \frac{\delta}{\nu}$, or

(b) $\alpha + \beta > 0, \quad \eta^* := \frac{2(1 + \nu\alpha + (1 + \nu\beta)(\nu + 1)^2)}{2\nu^2(\nu + 1)} > 0$.

Set $\lambda = 1 + \frac{\delta}{\nu}$ and $S := (1 - \lambda)\Id + \lambda\Prox_{\gamma^*} - \delta \nabla h\Prox_{\gamma^*}$. Let $(x_n)_{n \in \mathbb{N}}$ be a sequence generated by $T_{f, g, h}$ in (76). Then the following hold:

(i) $T_{f, g, h}$ is contractively $\frac{\eta^*}{\nu}$-averaged and has full domain.

(ii) If $\zer(\hat{f}g + \hat{g}g + \nabla h) \neq \emptyset$ and $\eta < \eta^*$, then the rate of asymptotic regularity of $T_{f, g, h}$ is $o(1/\sqrt{n})$ and $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x^* \in \Fix T_{f, g, h}$ with

$$\Prox_{\gamma^*}x^* \in \zer(\hat{f}g + \hat{g}g + \nabla h) \subseteq \arginf(f + g + h),$$

while $(\nabla h\Prox_{\gamma^*}x_n)_{n \in \mathbb{N}}$ converges strongly to $\nabla h\Prox_{\gamma^*}x^*$ and

$$\nabla h(\zer(\hat{f}g + \hat{g}g + \nabla h)) = \{\nabla h\Prox_{\gamma^*}x^*\}.$$ Moreover, when (a) holds, $(\Prox_{\gamma^*}x_n)_{n \in \mathbb{N}}$ and $(\Prox_{\gamma}Sx_n)_{n \in \mathbb{N}}$ converge weakly to $\Prox_{\gamma^*}x^* = \Prox_{\gamma}Sx^*$; when (b) holds, $(\Prox_{\gamma^*}x_n)_{n \in \mathbb{N}}$ and $(\Prox_{\gamma}Sx_n)_{n \in \mathbb{N}}$ converge strongly to $\Prox_{\gamma^*}x^* = \Prox_{\gamma}Sx^*$ and $\zer(\hat{f}g + \hat{g}g + \nabla h) = \{\Prox_{\gamma^*}x^*\}$.

Proof As in the proofs of Theorems 4.1 and 4.5, we have that $1 + \nu \alpha > 0$ and $1 + \delta \beta > 0$. By Lemma 6.1, $\hat{f}g$ and $\hat{g}g$ are maximally $\alpha$-monotone and $\beta$-monotone, respectively, and $\Prox_{\gamma^*} = I_{\hat{f}g}$ and $\Prox_{\gamma} = I_{\hat{g}g}$. By [6, Theorem 18.15(i)&(v)], $\nabla h$ is $\sigma$-cocoercive. In addition, from Proposition 2.1 and [11, Lemma 5.3], we obtain the relationship between the fixed points of $T_{f, g, h}$ and the minimizers of (75)

$$\Prox_{\gamma^*}(\Fix T_{f, g, h}) = \zer(\hat{f}g + \hat{g}g + \nabla h) \subseteq \arginf(f + g + h).$$

The conclusion then follows by applying Theorems 4.1 and 4.5 to $A = \hat{f}g$, $B = \hat{g}g$, and $C = \nabla h$. \qed

Remark 6.3 (minimizing the sum of two functions) Analogous to Sect. 5, one can apply Theorem 6.2 with $f = 0, g = 0$, or $h = 0$ to obtain corresponding algorithms for minimizing the sum of two functions.
