Abstract

Variational Monte Carlo calculations have been made for the $^{17}_{\Lambda}O$ hypernu-
cleus using realistic two- and three-baryon interactions. A two pion exchange
potential with spin- and space-exchange components is used for the $\Lambda N$ poten-
tial. Three-body two-pion exchange and strongly repulsive dispersive $\Lambda NN$
interactions are also included. The trial wave function is constructed from
pair- and triplet-correlation operators acting on a single particle determinant.
These operators consist of central, spin, isospin, tensor and three- baryon po-
tential components. A cluster Monte Carlo method is developed for noncentral
correlations and is used with up to four-baryon clusters in our calculations.
The three-baryon $\Lambda NN$ force is discussed.

I. INTRODUCTION

In this paper we initiate a variational Monte Carlo study of hypernuclei using realistic two- and three-baryon interactions involving a $\Lambda$ and nucleons. In the past, variational calculations of the $s$-shell hypernuclei, a few $p$-shell hypernuclei using appropriate models and $\Lambda$ binding to nuclear matter were performed using mostly simplified and central nucleon-nucleon (NN) interactions. The aims of these calculations have largely been to deduce information about the $\Lambda$-nucleon ($\Lambda N$) and $\Lambda$-nucleon-nucleon ($\Lambda NN$) interactions. In addition, as a result of these studies, one could also explore the structure of hypernuclei.

The reason for using simplified NN interactions is the hope that the uncertainties in the NN interaction will largely cancel out in these calculations. This is because the $\Lambda$-separation energies $B_\Lambda$, which are the main experimental input in these calculations, are the differences of the energies of hypernuclei and their cores, i.e., $-B_\Lambda = A_\Lambda E_{\Lambda N} - (A-1)E_{\Lambda NN}$, where $A_\Lambda E_{\Lambda N}$ is the total energy of the hypernucleus and $(A-1)E_{\Lambda NN}$ is the ground state energy of the core nucleus. However, interactions generate strong NN correlations in the nuclear wave function. A realistic NN interaction will generate central, spin, spin-isospin, tensor and other two-nucleon correlations. In addition, there are significant three-nucleon correlations. In a hypernucleus, because of the operator dependence, these correlations may interact in a complicated manner with the $\Lambda N$ and $\Lambda NN$ correlations. This whole group of correlations then interact with the two- and three-body operators of the two- and three-baryon interactions. This can result in important contributions to the $\Lambda$-binding energy compared to the use of only central NN correlations generated by purely central NN interactions.

In this study, we use realistic two- and three-nucleon interactions and wave functions to see their effects on hypernuclei. There is another important aspect of the present study, the development of a methodology and variational program for hypernuclei. For the $p$-shell hypernuclei, we adopt the cluster Monte Carlo (CMC) technique developed in Ref. which we refer to as PWP. As a first step, we study $^{17}_\Lambda$O. Generalization to $^{16}_\Lambda$O will be straightforward. Further development of the one-body part of the nuclear wave functions
will be needed for other p-shell hypernuclei. We intend to cover a wide range of hypernuclei in order to have reliable information on three-baryon forces, because in this study we find that the role of the three-body ΛNN interaction is greatly altered from that found in some previous studies.

There are a few calculations of hypernuclei in which realistic NN forces have been used. One such calculation is by J. Carlson [8] in which he explicitly considers the ΛN → ΣN channel in $^5_\Lambda$He and $^4_\Lambda$He using the Nijmegen interaction. This study shows that the Nijmegen interaction underbinds the four-body hypernuclei and that the five-body hypernucleus is unbound relative to a separated α and Λ particle. Also, it does not reproduce the spin-splitting in the four-body hypernuclei. To resolve the classical over-binding [1,9,10] problem of $^5_\Lambda$He, Bando and Shimoda [11], and Shinmura et al. [12] have also performed calculations with Reid soft core and Hamada-Johnston NN potentials by calculating effective interactions using a G-matrix approach. All these calculations of the Λ-separation energies $B_\Lambda$ are confined to s-shell hypernuclei.

Since no experimental data for $^{17}_\Lambda$O exists, we generate "pseudo-experimental" or semi-empirical data for this system. This is done in Sec. II where we also briefly discuss the experimental status of Λ-separation energy data. In Sec. III we review the Λ and nucleon two- and three-body potentials. Section IV deals with the variational wave function. In Sec. V we describe the techniques of our calculations for $^{17}_\Lambda$O. In Sec. VI we present our results, and Sec. VII contains our conclusions.

II. Λ-SEPARATION ENERGIES

If we combine the results of previous experiments summarized in Ref. [13], the in-flight reaction (K$^-$, π$^-$), [14–16] and the associated production [17] (π$^+$,K$^+$), we have now almost 30 well established hypernuclei with a wide range of baryon numbers $A \leq 81$ and orbital angular momentum $\ell_\Lambda \leq 3$. The hypernuclei that are relevant for the empirical determination of the $B_\Lambda$ value of $^{17}_\Lambda$O are $^{11}_\Lambda$C, $^{12}_\Lambda$C, $^{13}_\Lambda$C, $^{16}_\Lambda$O, $^{28}_\Lambda$Si, $^{32}_\Lambda$S, $^{40}_\Lambda$Ca, $^{51}_\Lambda$V, and $^{89}_\Lambda$Y.
We use here three approaches for the empirical $B_\Lambda$ value of $^{17}_\Lambda$O. In the first approach [18], microscopic calculations of $B_\Lambda$ of the above hypernuclei were carried out with phenomenological two- and three-body $\Lambda N$ and $\Lambda NN$ interactions that were previously obtained from studies of $\Lambda p$ scattering, the s-shell hypernuclei, $^9_\Lambda$Be as a representative of p-shell hypernuclei in the $2\alpha + \Lambda$ model, and the $\Lambda$-binding to nuclear matter [2–4]. The $\Lambda$-separation energies $B_\Lambda$ are obtained from a Schrödinger equation with a $\Lambda$-nucleus potential $U_\Lambda$ and an effective mass $m^*_\Lambda$ which are obtained in the local-density approximation using the Fermi hypernetted chain technique for the $\Lambda$ binding to nuclear matter. Such a procedure gives a good account of the $B_\Lambda$ data of the above hypernuclei for $\ell_\Lambda \leq 3$. Using this procedure, we calculate the difference, $\Delta B_\Lambda$, of the $\Lambda$-separation energies of $^{17}_\Lambda$O and $^{16}_\Lambda$O. This gives $\Delta B_\Lambda = 0.30$ MeV.

In the second approach, we use the purely phenomenological technique adopted by Millener et al. [19]. Here we use a Woods-Saxon $\Lambda$-nucleus potential whose parameters were fitted to the $B_\Lambda$ data of the above mentioned hypernuclei,

$$U_\Lambda(r) = \frac{V_{0\Lambda}}{1 + \exp\left(\frac{r - c}{a}\right)},$$

(2.1)

where, $V_{0\Lambda} = -28.0$ MeV, $c=(1.128+0.439A^{-2/3})A^{1/3}$ and $a=0.6$ fm give a very good account of the $B_\Lambda$ data. This procedure gives $\Delta B_\Lambda=0.40$ MeV.

In the third approach, we consider a density-dependent $\Lambda$-nucleus potential [19–21] of the form

$$U_\Lambda(r) = A\rho(r) + B\rho^{4/3}(r),$$

(2.2)

where $\rho(r)$ represents the nucleon density. These are taken from Ref. [22]. We choose s- and p-orbits in $^{16}_\Lambda$O and the p- and f-orbits in $^{89}_\Lambda$Y to fix the parameters A and B. The experimental binding energies are $12.5 \pm 0.35$ and $2.5 \pm 0.5$ MeV in $^{16}_\Lambda$O and $16.0 \pm 1.0$ and $2.5 \pm 1.0$ MeV in $^{89}_\Lambda$Y. Fitting these energies results in a reasonable fit to all binding energies from $^{11}_\Lambda$C to $^{89}_\Lambda$Y for $\ell_\Lambda \leq 3$. The resulting $\Delta B_\Lambda$ is $0.76$ MeV.
If we combine the results of the above three approaches and at the same time bear in mind that the experimental uncertainty in the $B_\Lambda$ value of $^{16}_\Lambda$O is ±0.35 MeV, we may reliably fix the empirical $B_\Lambda$ value of $^{17}_\Lambda$O as 13.0 ± 0.4 MeV. We shall make use of this value in our calculations. Other approaches, such as relativistic mean-field theories or the local-density approximation using a Skyrme interaction can also be employed in the empirical determination of the $B_\Lambda$ value of $^{17}_\Lambda$O. But, since these approaches are consistent with the approaches that we have adopted above, we do not feel that their inclusion will affect our results.

### III. HAMILTONIAN

In an $A$-baryon hypernucleus, we will consider the first $A-1$ baryons to be nucleons. We will use $\Psi$ to refer to the full wavefunction of the hypernucleus and $\Psi_N$ to refer to the ground-state wave function of the $A-1$ nucleons. The full Hamiltonian $H$ can be written as

$$H = H_N + H_A,$$

where $H_N$ is the nucleon Hamiltonian:

$$H_N = - \frac{\hbar^2}{2m} \nabla_i^2 + \sum_{i<j} v_{ij} + \sum_{i<j<k} V_{ijk},$$

and

$$H_A = - \frac{\hbar^2}{2m_\Lambda} \nabla_\Lambda^2 + \sum_{i=1}^{A-1} v_{i\Lambda} + \sum_{i<j} V_{ij\Lambda},$$

is the part of the full Hamiltonian due to the $\Lambda$-particle.

The $\Lambda$-separation energy, $B_\Lambda$, of a hypernucleus is then given by

$$B_\Lambda = \frac{\langle \Psi_N | H_N | \Psi_N \rangle}{\langle \Psi_N | \Psi_N \rangle} - \frac{\langle \Psi | H | \Psi \rangle}{\langle \Psi | \Psi \rangle}.\quad (3.4)$$

Our goal is to calculate $B_\Lambda$ using a variational principle for the two components of Eq.(3.4). In this section we briefly describe the two- and three-body baryon interactions that we have used in this study.
A. ΛN potential

Two-pion-exchange (TPE) is a dominant part of the ΛN potential, that in turn is mainly determined by the strong tensor one-pion-exchange (OPE) component acting twice. Moreover, there is the K-exchange interaction that primarily contributes to the ΛN exchange potential. The tensor part of the ΛN interaction is very weak because the shorter range $\bar{K}$- and $K^*$-exchanges that are responsible for this are of opposite sign and nearly cancel each other. (In the case of the NN interaction the $\pi$-exchange and $\rho$-exchange tensor components do not cancel so completely, because their masses are quite different.)

We use an Urbana-type [23] potential with spin- and space-exchange components and a TPE tail which is consistent with $\Lambda p$ scattering below the $\Sigma$ threshold,

$$v_{\Lambda N}(r) = v_0(r)(1 - \epsilon + \epsilon P_x) + \frac{1}{4} v_\sigma T_\pi^2(r) \sigma_\Lambda \cdot \sigma_N,$$  \hspace{1cm} (3.5)

$$v_0(r) = v_c(r) - \bar{v}T_\pi^2(r),$$  \hspace{1cm} (3.6)

$$v_c(r) = \frac{W_c}{1 + e^{(r-R)/a}},$$  \hspace{1cm} (3.7)

where $T_\pi(r)$ is the OPE tensor potential

$$T_\pi = \left(1 + \frac{3}{x} + \frac{3}{x^2}\right) \frac{e^{-x}}{x} \left(1 - e^{-cx^2}\right)^2,$$  \hspace{1cm} (3.8)

$x=\mu r$, $\mu=0.7$ fm$^{-1}$ is the pion mass, and the cut-off parameter $c=2.0$ fm$^{-2}$. $P_x$ is the space exchange operator and $\epsilon$ is the corresponding exchange parameter. The $\bar{v} \equiv (v_s + 3v_t)/4$ and $v_\sigma \equiv v_s - v_t$ are respectively the spin-average and spin-dependent strengths, where $v_s$ and $v_t$ denote the singlet and triplet state depths, respectively. (Note that following the convention of Ref. [3], the Hamiltonian effectively contains $+v_c$, $-\bar{v}$, $+v_\sigma$, $-v_s$, and $-v_t$.) Finally, $v_c(r)$ is a short range Saxon-Wood repulsive potential. The various parameters are

$$v_s = 6.33\text{ MeV},\ v_t = 6.1\text{ MeV},\ \epsilon = 0.3,\ W_c = 2137\text{ MeV},\ R = 0.5\text{ fm},\ a = 0.2\text{ fm}.$$  \hspace{1cm} (3.9)
These parameters are consistent with the low energy $\Lambda p$ scattering data that essentially determine the spin-average potential $\bar{V}$. The parameter $\epsilon$ for the space-exchange strength is fairly well determined from the $\Lambda$ single-particle scattering data [18]. For a detailed account of the determination of the other parameters see Ref. [2]. We point out that because of the non-central $\Lambda N$ and $\Lambda NN$ correlations introduced in the next section, the $\Lambda N$ spin-spin potential will have a non-zero contribution even in a closed-shell system such as $^{17}_\Lambda O$.

**B. $\Lambda NN$ potential**

When a $\Lambda N$ potential that fits the $\Lambda p$ scattering is used, the $B_\Lambda$ for hypernuclei with $A \geq 5$ are almost a factor of two too large. This is an old result that has been confirmed by various analyses. In the present work we also find that the use of a realistic NN interaction does not alleviate this over-binding problem. As in the previous studies, to resolve the over-binding problem, we incorporate a three-body $\Lambda NN$ interaction.

We consider here two types of $\Lambda NN$ potentials that arise from projecting out $\Sigma, \Delta$, etc. degrees of freedom from a coupled channel formalism. These are the dispersive and the TPE $\Lambda NN$ potentials designated as $V_{\Lambda NN}^D$ and $V_{\Lambda NN}^{2\pi}$, respectively (see Fig. 1). $V_{\Lambda NN}^D$ is expected to be repulsive, and, following Ref. [2], we assume the phenomenological form

$$V_{\Lambda NN}^D = W_0 T_{\pi}^2(r_{1\Lambda}) T_{\pi}^2(r_{2\Lambda}), \quad (3.10)$$

where $W_0$ is the strength of the potential and $T_{\pi}(r_{i\Lambda})$ is given by Eq.(3.8). $V_{\Lambda NN}^{2\pi}$ consists of two parts corresponding to $p$ and $s$ wave $\pi \Lambda$ interactions [24]

$$V_{\Lambda NN}^{2\pi} = W_p + W_s, \quad (3.11)$$

where

$$W_p = -\left(\frac{C_p}{6}\right) (\tau_1 \cdot \tau_2) (\sigma_1 \cdot r_{1\Lambda}) (\sigma_2 \cdot r_{2\Lambda}) (\mu r_{1\Lambda} + 1)(\mu r_{2\Lambda} + 1)Y(r_{1\Lambda})Y(r_{2\Lambda}), \quad (3.12)$$

$$W_s = \frac{C_s (\tau_1 \cdot \tau_2) (\sigma_1 \cdot r_{1\Lambda}) (\sigma_2 \cdot r_{2\Lambda}) (\mu r_{1\Lambda} + 1)(\mu r_{2\Lambda} + 1)Y(r_{1\Lambda})Y(r_{2\Lambda})}{(\mu r_{1\Lambda} r_{2\Lambda})^2}, \quad (3.13)$$
\[ Y(r) = \frac{e^{-\mu r}}{\mu r} \left( 1 - e^{-\nu r^2} \right), \quad (3.14) \]

\[ \{A, B\} = AB + BA, \quad (3.15) \]

and

\[ X_{i\Lambda} = (\sigma_i \cdot \sigma_\Lambda) Y(r_{i\Lambda}) + S_{i\Lambda} T_\pi (r_{i\Lambda}). \quad (3.16) \]

Here \( X_{i\Lambda} \) is the one-pion exchange operator, and \( S_{i\Lambda} \) is the tensor operator. The component \( W_s \) is quite weak and, as in previous studies, we neglect it here; we feel that its effect should be studied in future work.

There are theoretical as well as phenomenological estimates for \( C_p \); but for \( W_0 \) the estimates are purely phenomenological. For example, for \( W_0 \approx 0.02 \), the reduction in the \( \Lambda \)-binding to nuclear matter (using central correlations) is approximately in accord with the suppression obtained in coupled channel \( (\Lambda N \rightarrow \Sigma N) \) reaction matrix calculations. For \( C_p \) theoretical estimates give 1~2 MeV; however, the phenomenological values may not lie in this region as the results depend sensitively on the cutoff parameter \( c \) that appears in Eq. (3.8). In the present study, we have obtained results as a function of the values of these parameters.

### C. Two- and three-nucleon potentials

For the nuclear part of the Hamiltonian, we use NN and NNN potentials that have been previously used to study various nuclei, including \( ^{16}O \) \[7\]. The NN potential contains the first six terms of the Argonne \( v_{14} \) \[25\] potential and a Coulomb term:

\[ v_{ij} = \sum_{p=1}^{6} v^p(r_{ij}) O_{ij}^p + v_{Coul}(r_{ij}) O_{ij}^{Coul} \quad (3.17) \]

where the operators are

\[ O_{ij}^{p=1,6} = 1, \tau_i \cdot \tau_j, \sigma_i \cdot \sigma_j, (\sigma_i \cdot \sigma_j) (\tau_i \cdot \tau_j), S_{ij}, S_{ij} (\tau_i \cdot \tau_j), \]

\[ O_{ij}^{Coul} = \frac{1}{4} (1 + \tau_{z,i})(1 + \tau_{z,j}). \quad (3.18) \]
We shall also refer to these operators by the abbreviations $c$, $\tau$, $\sigma$, $\sigma\tau$, $t$, and $t\tau$. In PWP it was found that the $7 \leq p \leq 14$ terms of Argonne $v_{14}$ and the corresponding $p = 7, 8$ correlation operators gave a net contribution of only $-0.45$ MeV/nucleon. We assume that the presence of a $\Lambda$ will not significantly modify this result and hence we can safely omit all potential and correlation operators for $p \geq 7$ when computing $B_A(\Lambda^7O)$.

The NNN potential is of the Urbana type, which consists of dispersive and two-pion-exchange terms:

\[
V_{ijk} = V_{ijk}^D + V_{ijk}^{2\pi},
\]

\[
V_{ijk}^D = \sum_{cyc} U_0 T_\pi^2(r_{ij}) T_\pi^2(r_{jk}),
\]

\[
V_{ijk}^{2\pi} = \sum_{cyc} A_0 \left( \{X_{ij}, X_{jk}\} \{\tau_i \cdot \tau_j, \tau_j \cdot \tau_k\} + \frac{1}{4} [X_{ij}, X_{jk}] [\tau_i \cdot \tau_j, \tau_j \cdot \tau_k] \right),
\]

where the square brackets represent the commutator $[A, B] = AB - BA$. The constants $A_0$ and $U_0$ have the values -0.0333 and 0.0038 in Urbana model VII [26], which we use here.

**IV. THE VARIATIONAL WAVE FUNCTIONS**

We assume that a good variational wavefunction for a hypernucleus with a closed-shell nuclear core and a $\Lambda$-particle can be written as

\[
|\Psi> = \left[ \prod_{ij} (1 + U_{ij\Lambda} + U_{ij}) \right] \left[ \prod_{i=1}^{A-1} (1 + U_{i\Lambda}) \right] \left[ \prod_{i<j}^{A-1} (1 + U_{ij}) \right] |\Psi_J>,
\]

\[
|\Psi_J> = \prod_{i=1}^{A-1} f_i^\Lambda(r_i\Lambda) \prod_{i<j}^{A-1} f_{ij}(r_{ij}) \phi_i(\Lambda r_\Lambda) \Phi_{\Lambda-1}. \]

Here $U_{ijk}$ represents a three-baryon correlation operator that has the same structure as $V_{ijk}$,

\[
U_{ijk} = \delta \tilde{V}_{ijk},
\]

\[
U_{ij\Lambda} = \delta_{\Lambda} \tilde{V}_{ij\Lambda}. \]
The $\tilde{V}_{ijk}$ differs from $V_{ijk}$ through the range $c$ of the cutoff functions of $Y_\pi(r)$ and $T_\pi(r)$. The parameter $\delta$ is referred to as $\epsilon$ in PWP; we use $\delta$ here to avoid confusion with the $\epsilon$ of the space-exchange potential in Eq. (3.5). The parameters $\delta$, $\delta_\Lambda$, $c$ and $c_\Lambda$ are determined variationally. The label IT stands for independent triplet product of $1+U_{ijk}$. Thus,

$$
\prod_{IT} (1 + U_{ijk} + U_{ij\Lambda}) = 1 + \sum_{i<j} U_{ij\Lambda} + \sum_{i<j,k} U_{ijk}U_{i'j'k'} + \sum_{i<j<k} U_{ijk} + \sum_{i<j<k} U_{ijk}U_{i'j'k'} + \cdots
$$

(4.5)

The neglected terms are of the type $U_{ijk}U_{i'j'k'}$. This restriction makes the three-body correlations much simpler to use. As is discussed in PWP, the $U_{ijk}$ and $U_{ij\Lambda}$ should ideally act last as in Eq. (4.1). However, this requires considerably more computer time. The improvement in the energy of $^{16}$O obtained by this was found to be only -0.19(7) MeV/nucleon. In the present work we ignore this correction and compute the energies of both $^{17}_\Lambda O$ and $^{16}$O with the three-baryon correlations acting first.

Each operator in the two-baryon interaction can induce the corresponding correlation. The $f^\Lambda_c$ and the $f_c$ are central correlations that are primarily generated by the repulsive cores in the two-baryon interactions. For $U_{ij}$ and $U_{i\Lambda}$, we make the following choice

$$
U_{ij} = \sum_{p=2}^{n} \beta_p u_p(r_{ij})O^p_{ij},
$$

(4.6)

and

$$
U_{i\Lambda} = \sum_{p=2}^{m} u^\Lambda_p(r_{i\Lambda})O^p_{i\Lambda}.
$$

(4.7)

The notation $S \prod$ in Eq. (4.1) represents a symmetrized-product of the non-commuting operators $U_{ij}U_{jk}\cdots$. Previous studies [3,4] on few-body nuclei and $^{16}$O demonstrate that it is probably sufficient to use $2 \leq p \leq 6$ in Eq. (4.6). The pair correlation functions $f_c$ and $u_p$ are generated by minimizing the two-body cluster energy using a quenched potential:

$$
\tilde{v}_{ij} = \sum_{p=2}^{6} \alpha u_p(r_{ij})O^p_{ij}.
$$

(4.8)
The two-body cluster contribution has been minimized for infinite nuclear matter at Fermi momentum $k_F$, with the boundary conditions $f_c(r > d) = 1$, and $u_p(r > d) = 0$, for $p = \tau, \sigma$, and $\sigma\tau$, and $u_p(r > d_t) = 0$, for $p = t$ and $t\tau$ with their first derivatives zero at $r = d$ or $d_t$.

For the $U_{i\Lambda}$ we consider

$$U_{i\Lambda} = u^\Lambda_{i\Lambda}(r_{i\Lambda})\sigma_i \cdot \sigma_i + u_{P_x}(r_{i\Lambda})P_x. \tag{4.9}$$

In the present study, we have omitted the second, i.e., the exchange correlation term in Eq.(4.9). Inclusion of this term increases the computation effort by several fold and preliminary results indicate that it gives a small contribution. This will be the subject of a future publication. The spin correlation is

$$u^\Lambda_{\sigma} = \frac{f^\Lambda_\sigma - f^\Lambda_t}{f^\Lambda_c}, \tag{4.10}$$

where $f^\Lambda_s$ and $f^\Lambda_t$ are the solutions of Schroedinger equations with quenched $\Lambda N$ potentials in singlet and triplet states respectively:

$$\left[-\frac{\hbar^2}{2\mu_{\Lambda N}} \nabla^2 + \bar{v}_{s(t)}(r_{\Lambda N})\right] f^\Lambda_{s(t)} = 0. \tag{4.11}$$

The potentials $\bar{v}_{s(t)}$ are quenched in the two-pion and spin-exchange parts of the central and spin channels:

$$\bar{v}_s(r) = v_c(r) - (\alpha_{2\pi} \bar{v} + \frac{3}{4} \alpha_{\sigma} v_\sigma)T^2_\pi(r), \tag{4.12}$$

$$\bar{v}_t(r) = v_c(r) - (\alpha_{2\pi} \bar{v} - \frac{1}{4} \alpha_{\sigma} v_\sigma)T^2_\pi(r). \tag{4.13}$$

The spin-averaged correlation function $f^\Lambda_c$ is given by:

$$f^\Lambda_c = \frac{f^\Lambda_s + 3f^\Lambda_t}{4}. \tag{4.14}$$

The $f^\Lambda_s, f^\Lambda_t$ and $f^\Lambda_c$ have been obtained by minimizing the two-body cluster energy for the $\Lambda$-binding to nuclear matter with the asymptotic condition $f^\Lambda_c(r > d_\Lambda) = 1$.

The $\phi_\Lambda$ represents a bound-state wavefunction of a $\Lambda$-particle of mass $m_\Lambda$ moving in a Woods-Saxon potential that is bound to a nucleus of mass $(A-1)m$:
\[ V_A(r_A) = \frac{V_A}{1 + \exp\left(\frac{r_A - R_A}{a_A}\right)}. \]  

(4.15)

The parameters \( V_A, R_A \) and \( a_A \) are determined variationally. The Slater determinant \( A \left| \Phi_{A-1} \right\rangle \) consists of orbitals of nucleons of mass \( m \) bound to a hypernucleus of mass \((A-2)m + m_A\) moving in a Woods-Saxon wine-bottle potential

\[ V(r) = V_s \left( \frac{1}{1 + e^{(r-R_s)/a_s}} - \alpha_s e^{-(r/\rho_s)} \right), \]  

(4.16)

with \( V_s, R_s, a_s, \alpha_s, \) and \( \rho_s \) as variational parameters. The coordinates of all the one-body orbitals are measured from the center of mass of the whole system, thus making \( \Psi_J \) and \( \Psi \) translationally invariant, i.e.,

\[ \tilde{r}_i = r_i - R_{\text{c.m.}}, \]  

(4.17)

\[ R_{\text{c.m.}} = \frac{m\sum_{i=1}^{A-1} r_i + m_A r_A}{m(A-1) + m_A}. \]  

(4.18)

V. THE CLUSTER EXPANSION

We briefly outline the general framework for the cluster expansion of PWP to calculate the expectation values of various operators. These expectation values are needed in the evaluation of the energy using the variational wave function (4.1). We demonstrate the cluster expansion for the two-body NN and \( \Lambda N \) potentials:

\[ \frac{\langle \Psi | \sum v_{ij} + \sum v_{i\Lambda} | \Psi \rangle}{\langle \Psi | \Psi \rangle} = \frac{N}{D}. \]  

(5.1)

The \( N \) and \( D \) can be expanded as a sum of \( n \)-body contributions

\[ N = \sum_{i<j}^{A-1} n_{ij} + \sum_{i=1}^{A-1} n_{i\Lambda} + \sum_{i<j<k}^{A-1} n_{ijk} + \sum_{i<j}^{A-1} n_{ij\Lambda} + \cdots, \]  

(5.2)

\[ D = 1 + \sum_{i<j}^{A-1} d_{ij} + \sum_{i=1}^{A-1} d_{i\Lambda} + \cdots. \]  

(5.3)
The expressions for the purely nuclear \( n_{ij}, d_{ij}, n_{ijk}, \) etc., may be found in PWP. The contributions of clusters containing a \( \Lambda \) are similar, e.g.

\[
\begin{align*}
n_{i\Lambda} &= \left\langle (1 + U_{i\Lambda})^\dagger v_{i\Lambda} (1 + U_{i\Lambda}) \right\rangle, \\
d_{i\Lambda} &= \left\langle (1 + U_{i\Lambda})^\dagger (1 + U_{i\Lambda}) \right\rangle - 1,
\end{align*}
\]

\[
\begin{align*}
n_{ij\Lambda} &= \left\langle (1 + U_{ij\Lambda}) (1 + U_{ij\Lambda}^\dagger) P \left[ (1 + U_{i\Lambda}) (1 + U_{j\Lambda})^\dagger \right] [v_{ij} + v_{i\Lambda} + v_{j\Lambda}] \right. \\
&\quad \times P' \left[ (1 + U_{i\Lambda}) (1 + U_{j\Lambda}) (1 + U_{ij}) (1 + U_{ij\Lambda}) \right] \left\rangle - n_{ij} - n_{i\Lambda} - n_{j\Lambda},
\end{align*}
\]

where \( P \) and \( P' \) are permutation operators. In these expressions

\[
\langle \theta \rangle = \frac{\langle \Psi_J | \theta | \Psi_J \rangle}{\langle \Psi_J' | \Psi_J' \rangle},
\]

where \( \Psi_J' \) denotes the \( \Psi_J \) of Eq. (4.2) without the anti-symmetrization operator.

The expansions (5.2) and (5.3) for \( N \) and \( D \) are divergent \[7\]. We obtain a convergent linked-cluster expansion by expressing

\[
\frac{N}{D} = \sum_{i<j}^{A-1} c_{ij} + \sum_{i=1}^{A-1} c_{i\Lambda} + \cdots
\]

(5.8)

The various \( c_{ij} \) and \( c_{i\Lambda} \) etc. are obtained from the equation

\[
N = \left[ \sum_{i<j}^{A-1} c_{ij} + \sum_{i=1}^{A-1} c_{i\Lambda} + \cdots \right] D,
\]

(5.9)

by equating terms with the same \( ij, i\Lambda, ijk, ij\Lambda, \) etc. Thus,

\[
c_{i\Lambda} = \frac{n_{i\Lambda}}{1 + d_{i\Lambda}},
\]

(5.10)

and

\[
c_{ij\Lambda} = \frac{n_{ij\Lambda} - c_{ij}(d_{j\Lambda} + d_{i\Lambda}) - c_{i\Lambda}(d_{ij} + d_{j\Lambda}) - c_{j\Lambda}(d_{ij} + d_{i\Lambda}) - (c_{ij} + c_{i\Lambda} + c_{j\Lambda})d_{ij\Lambda}}{1 + d_{ij} + d_{i\Lambda} + d_{j\Lambda} + d_{ij\Lambda}}.
\]

(5.11)

In the present work, we have used the CEA expansion of PWP so that all clusters of a given spin, isospin, and \( \Lambda \) content are averaged together.
VI. RESULTS

A. Variational parameters

We made detailed variational parameter searches for two cases: 1) with no $\Lambda NN$ potential and hence no $U_{ij\Lambda}$ correlation, and 2) using a $\Lambda NN$ potential with $C_p = 0.7$ MeV and $W_0 = 0.015$ MeV. The rest of the Hamiltonian was as described in Sec. III for both cases; in particular the NNN potential and $U_{ijk}$ correlation were used in both cases.

For the case with no $\Lambda NN$ potential, we found that the optimal values of all of the nucleon correlation parameters are the same as was found in PWP for $^{16}O$, except that the well depth, $V_s$, of the Woods-Saxon potential changes from -49.1 MeV to -48.9 MeV to maintain the same p-wave separation energy, 14.0 MeV, with the 17-body instead of 16-body reduced mass. The reader is referred to PWP for these parameter values. The optimal parameters for correlation terms involving the $\Lambda$ are: for the $\Lambda$ Woods-Saxon well,

$$V_{\Lambda} = -28.3 \text{ MeV}; \quad R_{\Lambda} = 3.2 \text{ fm}; \quad a_{\Lambda} = 0.5 \text{ fm},$$

which gives an s-wave separation energy of 15.0 MeV; for the $U_{i\Lambda}$

$$\alpha_{2\pi} = \alpha_{\sigma} = 1.0; \quad d_{\Lambda} = 2.8 \text{ fm}.$$

In the presence of the $\Lambda NN$ potential with $C_p = 0.7$ MeV, $W_0 = 0.015$ MeV, we found that only two of the above optimal values had to be changed. These are the quenching parameters $\alpha$ in the $NN$ correlation and $\alpha_{2\pi}$ in the $NA$ correlation. The variational energy is sensitive to $\alpha$ and we made several searches at other values of $C_p$ to determine

$$\alpha = 0.94 - 0.1 C_p, \quad 0 \leq C_p \leq 1.2 \text{ MeV}.$$  \hspace{1cm} (6.3)

The sensitivity to $\alpha_{2\pi}$ is weak and we used

$$\alpha_{2\pi} = 0.95, \quad 0.7 \leq C_p \leq 1.2 \text{ MeV}.$$  \hspace{1cm} (6.4)

In addition to these parameters we found for the $U_{NNA}$
\[ \delta_\Lambda = -0.0013; \quad c_\Lambda = 1.6 \text{ fm}^{-2}, \tag{6.5} \]

for all \( C_p \) and \( W_0 \) considered.

**B. Variational energies**

Tables I and II show various components of the \(^{17}\Lambda\text{O}\) energy for the cases of no \( \Lambda\text{NN} \) potential and \( C_p = 0.7 \text{ MeV}, \ W_0 = 0.015 \) respectively. The cluster expansion for terms involving the \( \Lambda \) is converging well and it appears that it is not necessary to extrapolate beyond the four-body clusters for these terms. To get an accurate total energy of the \(^{17}\Lambda\text{O}\) nucleus, it would be necessary to extrapolate the values of \( V_{NNN} \) as was done in PWP. However since we are mainly interested in \( B_\Lambda \), we do not do that here and instead subtract an unextrapolated \(^{16}\text{O}\) energy.

One important result shown in Table II is that the expectation of \( V_{2\pi}^{\Lambda} \) is substantial and negative. This arises from the non-central correlations in the wave function. A purely Jastrow wave function \( (U_{ij} = U_{ijk} = U_{i\Lambda} = U_{ij\Lambda} = 0) \) gives \( \langle V_{2\pi}^{\Lambda NN} \rangle = 0.9 \text{ MeV} \); including \( U_{ij} \) (with \( \alpha = 0.94 \)), \( U_{ijk} \), and \( U_{i\Lambda} \) (with \( \alpha_{2\pi} = 1.0 \)), but no \( U_{ij\Lambda} \), results in \( \langle V_{2\pi}^{\Lambda NN} \rangle = -4.2 \text{ MeV} \). Including \( U_{ij\Lambda} \) also but still keeping \( \alpha = 0.94 \), \( \alpha_{2\pi} = 1.0 \), gives \( \langle V_{2\pi}^{\Lambda NN} \rangle = -7.9 \text{ MeV} \), while lowering \( \alpha \) to the optimal value of 0.87 and \( \alpha_{2\pi} \) to 0.95 reduces this to -5.0 MeV (this loss of binding is offset by changes in the expectation values of other parts of the Hamiltonian).

These results can be understood as follows: by using the relation

\[ \sigma \cdot A \sigma \cdot B = A \cdot B + i \sigma \cdot (A \times B), \tag{6.6} \]

the \( \{X_{1\Lambda}, X_{2\Lambda}\} \) appearing in \( V_{2\pi}^{\Lambda NN} \) can be expressed in terms of the operators \( \sigma_1 \cdot r_{1\Lambda} \sigma_2 \cdot r_{2\Lambda} \), \( \sigma_1 \cdot r_{1\Lambda} \sigma_2 \cdot r_{1\Lambda}, \sigma_1 \cdot r_{2\Lambda} \sigma_2 \cdot r_{2\Lambda} \), and \( \sigma_1 \cdot \sigma_2 \) and hence is a generalization of the tensor operator \( S_{12} \). However the expectation value of \( S_{12} \) in a Jastrow wave function for a closed-shell nuclear system is zero, while the expectation value of \( S_{12}^2 \) is non-zero. Hence the \( S_{12} \) operator in \( U_{12} \) completely changes \( \langle V_{2\pi}^{\Lambda\text{Al}} \rangle \). Of course the \( U_{ij\Lambda} \) further enhances its contribution.
The $^{16}\text{O}$ energy that corresponds to the present calculation ($U_{ijk}$ acts first, use of only the first six operators in Argonne $v_{14}$, and no extrapolation) is $-101.0(9)$ MeV. We emphasize that, because of the above approximations, this energy is to be used only in comparison with the $^{17}\Lambda$O energies. The resulting $B_{\Lambda}(^{17}\Lambda\text{O})$ are $27.5(2.0)$ MeV for no $V_{\Lambda NN}$ and $13.5(1.8)$ MeV for $C_p = 0.7$, $W_0 = 0.015$, which are to be compared with the empirical value of $13.0(4)$ found in Sec. II. Thus even with realistic NN potentials and correlations, $^{17}\Lambda$O is very overbound if no $V_{\Lambda NN}$ is used. However a reasonable $V_{\Lambda NN}$ results in a $B_{\Lambda}$ consistent with the empirical value.

To study the dependence of $B_{\Lambda}$ on the strength of the $V_{\Lambda NN}$, we made a number of calculations with different values of $C_p$ and $W_0$. In each case the NN quenching parameter was chosen according to Eq. (6.3). To minimize statistical errors, we made correlated difference calculations using the $C_p = 0.7$, $W_0 = 0.015$ random walk. Table III presents the resulting changes, $\delta B_{\Lambda}$, in $B_{\Lambda}$. All of these values of $B_{\Lambda}$ and $\delta B_{\Lambda}$ are well fit by the formula

$$B_{\Lambda} = 27.3 - 8.9 C_p + 11.2 C_p^2 - 870. W_0; \quad (6.7)$$

the statistical error of $B_{\Lambda}$ is $\pm 1.6$ MeV. The quadratic dependence on $C_p$ comes from $U_{ij\Lambda}$; the contribution of the dispersive term in $U_{ij\Lambda}$ (and also in $U_{ijk}$) is very small. When comparable calculations of other hypernuclei are available, Eq. (6.7) and the empirical value of $B_{\Lambda}(^{17}\Lambda\text{O}) = 13.0(4)$ can be used to uniquely determine the values of $C_p$ and $W_0$ (or to show that a different Hamiltonian is needed if no fit can be found).

C. Densities and polarization of $^{16}\text{O}$ core

Figure 2 shows point nucleon and $\Lambda$ densities for the calculations of Tables I and II. The density of $^{16}\text{O}$ is also shown. For the case with no $V_{\Lambda NN}$, the nuclear correlation parameters were not changed from those used in $^{16}\text{O}$. The resulting $^{16}\text{O}$ density is, however, reduced near the origin and somewhat more peaked at $r = 1.4$ fm. This is presumably due to the repulsive $f_{\Lambda N}$ which pushes the nucleons away from the $\Lambda$ which is strongly localized near the origin.
With $V_{NN}$, the NN quenching parameter was significantly reduced. This results in a slightly more repulsive $f_c$ ($\alpha$ does not quench the central part of $V_{NN}$) and so the nuclear density is reduced for $r \lesssim 2.2$ fm. The nuclear kinetic and potential energies (see Tables I and II) for the no $V_{NN}$ case are separately larger in magnitude due to the higher density. It is probably accidental that the total nucleon energies for the two cases are so nearly the same: -90(2) MeV. This value is 11 MeV less than the corresponding binding energy of $^{16}$O, showing that the $\Lambda$ significantly reduces the binding of the nucleons.

The density profile of the $\Lambda$ for the two cases is also shown in Fig. 2, along with the density corresponding to the one-body part of $\Psi$, i.e. $|\phi_(r)|^2/4\pi$. In both cases the Jastrow part of $\Psi$, i.e. $\Pi f_c^\Lambda(r_{i\Lambda})$, significantly increases the $\Lambda$ density at the origin. This is presumably because $f_c^\Lambda$ is small for $r_{i\Lambda} \to 0$ and hence pushes the $\Lambda$ away from the high nuclear density around $r = 1.4$ fm. Because this density is larger for $V_{NN} = 0$, the central $\Lambda$ density is also larger in this case.

VII. CONCLUSIONS

In this study, we have extended the cluster Monte Carlo technique developed in PWP for $^{16}$O to $^{17}_{\Lambda}$O. The cluster contributions that involve the $\Lambda$ seem to converge well. It thus seems sufficient to include terms up to four-body clusters in the calculation. These calculations have been performed for a number of sets of $W_0$ and $C_p$ which will be helpful in determining the parameters of the three-body interaction $V_{ij\Lambda}$ by fitting the $B_{\Lambda}$ values of $^{17}_{\Lambda}$O and other hypernuclei. The present calculations show that the use of non-central NN, NNN, NA and NNA correlations completely change the expectation value of the three-baryon $\Lambda NN$ interaction found with central wave functions, and thus have a strong effect on the choice of the parameters $W_0$ and $C_p$. With such correlations, reasonable values of $C_p$ and $W_0$ give the correct $B_{\Lambda}(^{17}_{\Lambda}$O). We also find that the $\Lambda$ significantly changes the density profile and energy of the 16 nucleons in $^{17}_{\Lambda}$O; the $\Lambda NN$ potential is particularly significant in this regard.
ACKNOWLEDGMENTS

We thank R. B. Wiringa for many useful discussions. This work was supported by the Indo-US joint collaboration program for which the authors acknowledge NSF grant INT-9011046. This work was also supported in part by the U.S. Department of Energy, Nuclear Physics Division, under contract No. W-31-109-ENG-38. The calculations were made possible by a grant of computer time at the National Energy Research Supercomputer Center, Livermore, California. AAU is also grateful to Professor A. Zichichi, President, ICSC-World Laboratory, Lausanne, Switzerland for a fellowship, Professor S. Fantoni, Director, Interdisciplinary Laboratory, SISSA, 34014-Trieste, Italy for extending the facilities to complete this work, Professor Basheeruddin Ahmad, Vice Chancellor, Jamia Millia Islamia, New Delhi for a grant of leave and support, and Professor Abdus Salam, Director, International Center for Theoretical Physics, 34014 Trieste, Italy for inviting him to ICTP where part of the work was carried out. QNU acknowledges a DRS grant of the Department of Physics, Jamia Millia Islamia, New Delhi. SCP thanks Professor Q.N. Usmani and his wife, Tasneem, for their generous hospitality while he was in New Delhi, and Professor S. Fantoni for an invitation to SISSA, where part of this paper was written.
