Real Hamiltonian forms of Hamiltonian systems

V. S. Gerdjikov, A. Kyuldjiev, G. Marmo, and G. Vilasi

1 Introduction

Recently the so-called complex Toda chain (CTC) was shown to describe N-soliton interactions in the adiabatic approximation. The complete integrability of the CTC is a direct consequence of the integrability of the real (standard) Toda chain (TC); it was also shown that CTC allows several dynamical regimes that are qualitatively different from the one of real Toda chain. These results as well as the hope to understand the algebraic structures lying behind the integrability of CTC (such as, e.g. Lax representation) were the stimulation for the present work.

We start from a standard (real) Hamiltonian system \( \mathcal{H} \equiv \{\omega, H, \mathcal{M}\} \) with \( n \) degrees of freedom and Hamiltonian \( H \) depending analytically on the dynamical variables. It is known that such systems can be complexified and then written as a Hamiltonian system with \( 2n \) (real) degrees of freedom. Our main aim is to show that to each compatible involutive automorphism \( \tilde{C} \) of the complexified phase space we can relate a real Hamiltonian form of the initial system with \( n \) degrees of freedom. Just like to each complex Lie algebra one associates several inequivalent real forms, so to each \( \mathcal{H} \) we associate several inequivalent real forms \( \mathcal{H}_R \equiv \{\omega_R, H_R, \mathcal{M}_R\} \).

Received: date / Revised version: date

Abstract. We introduce the notion of a real form of a Hamiltonian dynamical system in analogy with the notion of real forms for simple Lie algebras. This is done by restricting the complexified initial dynamical system to the fixed point set of a given involution. The resulting subspace is isomorphic (but not symplectomorphic) to the initial phase space. Thus to each real Hamiltonian system we are able to associate another nonequivalent (real) one. A crucial role in this construction is played by the assumed analyticity and the invariance of the Hamiltonian under the involution. We show that if the initial system is Liouville integrable, then its complexification and its real forms will be integrable again and this provides a method of finding new integrable systems starting from known ones. We demonstrate our construction by finding real forms of dynamics for the Toda chain and a family of Calogero–Moser models. For these models we also show that the involution of the complexified phase space induces a Cartan-like involution of their Lax representations.

2 Complexified Hamiltonian Dynamics

We start with a real Hamiltonian system with \( n \) degrees of freedom \( \mathcal{H} \equiv \{ \mathcal{M}^{(n)}, H, \omega \} \) where \( \mathcal{M}^{(n)} \) is a 2\( n \) dimensional vector space and

\[
\omega = \sum_{k=1}^{n} dp_k \wedge dq_k \quad (1)
\]

Let’s consider its complexification:

\[
\mathcal{H}^C \equiv \{ \mathcal{M}^C, H^C, \omega^C \}
\]

where \( \mathcal{M}^{(2n)}_C \) can be viewed as a linear space \( \mathcal{M}^{(n)} \) over the field of complex numbers:

\[
\mathcal{M}^{(2n)}_C = \mathcal{M}^{(n)} \oplus i\mathcal{M}^{(n)}.
\]

In other words the dynamical variables \( p_k, q_k \) in \( \mathcal{M}^{(2n)}_C \) now may take complex values. We assume that observables \( F, G \) and the Hamiltonian \( H \) are real analytic functions on \( \mathcal{M} \) and can naturally be extended to \( \mathcal{M}^{(2n)}_C \).

The complexification of the dynamical variables \( F, G \) and \( H \) means that they become analytic functions of the complex arguments:

\[
p_k^C = p_{k,0} + ip_{k,1}, \quad q_k^C = q_{k,0} + iq_{k,1}, \quad k = 1, \ldots, n \pm (3)
\]

and we can write:

\[
H^C = H(p_k^C, q_k^C) = H_0 + iH_1. \quad (4)
\]

The same goes true also for the complexified 2–form:

\[
\omega^C = \sum_{k=1}^{n} dp_k^C \wedge dq_k^C = \omega_0 + i\omega_1 \quad (5)
\]

Note that each of the symplectic forms \( \omega_0 \) and \( \omega_1 \) are non-degenerate. However the linear combination \( \omega^C = \omega_0 + i\omega_1 \) can be written down in the form:

\[
\omega = \sum_{k=1}^{n} (dp_{k,0}, dp_{k,1}, dq_{k,0}, dq_{k,1}) B_0 \begin{pmatrix} dp_{k,0} \\ dp_{k,1} \\ dq_{k,0} \\ dq_{k,1} \end{pmatrix}
\]

where the matrix \( B_0 \)

\[
B_0 = \frac{1}{2} \begin{pmatrix} 0 & 0 & 1 & i \\ 0 & 0 & i & -1 \\ -1 & -i & 0 & 0 \\ -i & 1 & 0 & 0 \end{pmatrix}
\]

obviously has the property \( B_0^2 = 0 \).

**Remark 1** The kernel of \( \omega^C \) is spanned by the antiholomorphic vector fields. We could also choose the antiholomorphic (anti-analytic) functions in the complexification procedure. This would lead to equivalent results.

Obviously, \( \dim \mathcal{M}^C = 4n \) and therefore \( \mathcal{H}^C \) may be considered as a real dynamical system with 2\( n \) degrees of freedom. To elaborate on this, we start from the complexified equations of motion:

\[
\begin{align*}
\frac{dp_k^C}{dt} &= -\frac{\partial H^C}{\partial q_k^C}, \\
\frac{dq_k^C}{dt} &= \frac{\partial H^C}{\partial p_k^C}
\end{align*} \quad (6)
\]

The right hand side of (6) contain the partial derivatives of both \( H_0 \) and \( H_1 \). Since we assumed analyticity, \( H_0 \) and \( H_1 \) will satisfy the Cauchy-Riemann equations:

\[
\frac{\partial H_0}{\partial q_{k,0}} = \frac{\partial H_1}{\partial q_{k,1}}, \quad \frac{\partial H_0}{\partial q_{k,1}} = -\frac{\partial H_1}{\partial q_{k,0}}. \quad (7)
\]

which means that the derivatives in the right hand sides of (6) are equal to:

\[
\begin{align*}
\frac{\partial H^C}{\partial q_k^C} &= \frac{\partial H_0}{\partial q_{k,0}} - i \frac{\partial H_0}{\partial q_{k,1}}, \\
\frac{\partial H^C}{\partial q_k^C} &= \frac{\partial H_1}{\partial q_{k,1}} + i \frac{\partial H_1}{\partial q_{k,0}}.
\end{align*} \quad (8)
\]

Analogous formulae hold for the derivatives with respect to \( p_{k,0} \) and \( p_{k,1} \). Thus all terms in the right hand sides of (6) can be expressed through the partial derivatives of \( H_0 \) only:

\[
\begin{align*}
\frac{dp_{k,0}}{dt} &= \frac{\partial H_0}{\partial q_{k,0}}, \\
\frac{dp_{k,1}}{dt} &= \frac{\partial H_0}{\partial q_{k,1}}, \\
\frac{dq_{k,0}}{dt} &= \frac{\partial H_0}{\partial p_{k,0}}, \\
\frac{dq_{k,1}}{dt} &= -\frac{\partial H_0}{\partial p_{k,1}}.
\end{align*} \quad (9)
\]

Obviously (9) are standard Hamiltonian equations of motion for a dynamical system with 2\( n \) degrees of freedom corresponding to:

\[
\begin{align*}
H_0 &= \text{Re} \, H^C(p_k^C, q_k^C), \\
\omega_0 &= \text{Re} \, \omega^C = \sum_{k=1}^{n} (dp_{k,0} \wedge dq_{k,0} - dp_{k,1} \wedge dq_{k,1})
\end{align*} \quad (10)
\]

We denote the related real dynamical vector field by \( \Gamma_0 \).

The system (9) allows a second Hamiltonian formulation with:

\[
\begin{align*}
H_1 &= \text{Im} \, H^C(p_k^C, q_k^C), \\
\omega_1 &= \text{Im} \, \omega^C = \sum_{k=1}^{n} (dp_{k,0} \wedge dq_{k,1} + dp_{k,1} \wedge dq_{k,0})
\end{align*} \quad (11)
\]

and also real dynamical vector field \( \Gamma_1 \). Due to the analyticity of \( H^C \) Cauchy-Riemann equations yield that these two vector fields actually coincide:

\[
\Gamma_0 = \Gamma_1.
\]

So \( \Gamma_0 \) is a bi-Hamiltonian vector field and the corresponding recursion operator is:

\[
T = \omega_0^{-1} \circ \omega_1 =
\begin{align*}
- \frac{\partial}{\partial p_0} \wedge \frac{\partial}{\partial p_1} + \frac{\partial}{\partial q_0} \wedge \frac{\partial}{\partial q_1} - \frac{\partial}{\partial q_0} \wedge \frac{\partial}{\partial q_1} + \frac{\partial}{\partial p_0} \wedge \frac{\partial}{\partial p_1} \\
T^2 &= -1.
\end{align*}
\]
3 Complexification and Liouville integrability

Let us now assume that our initial system is Liouville integrable and analyze what consequences will have this on the complexified system.

**Proposition 1** Let the initial system \( \mathcal{H} \) have \( n \) functionally independent integrals \( I_k, \ k = 1, \ldots, n \) which are real analytic (meromorphic) functions of \( q_k \) and \( p_k \). Let also \( I_k \) be in involution:

\[
\{I_k, I_j\} \equiv \sum_{s=1}^{n} \left( \frac{\partial I_k}{\partial p_s} \frac{\partial I_j}{\partial q_s} - \frac{\partial I_k}{\partial q_s} \frac{\partial I_j}{\partial p_s} \right) = 0, \quad (13)
\]

Then the complexified system \( \{\mathcal{M}^C, H_0, \omega_0\} \) is also Liouville integrable, i.e. it has \( 2n \) functionally independent integrals \( I_{k,0}, I_{k,1}, k = 1, \ldots, n \) in involution.

**Proof** Obviously after the complexification each of the integrals \( I_k \) becomes complex-valued \( I_k^C = I_k^{00} + iI_k^{11} \). Since \( I_k \) is a real analytic function then \( I_k^C \) satisfies Cauchy-Riemann equations with respect to each of the complexified variables. Keeping this in mind let us complexify the dynamical variables in (13). Separating the real and the imaginary parts and making use of Cauchy-Riemann equations we get by direct calculation that:

\[
\{I_{k,0}, I_{j,0}\} = \{I_{k,0}, I_{j,1}\} = \{I_{k,1}, I_{j,1}\} = 0, \quad (14)
\]

where

\[
\{F, G\}_0 = \sum_{s=1}^{n} \left( \frac{\partial F}{\partial p_s,0} \frac{\partial G}{\partial q_s,0} - \frac{\partial F}{\partial q_s,0} \frac{\partial G}{\partial p_s,0} \right) + \frac{\partial F}{\partial p_s,1} \frac{\partial G}{\partial q_s,1} + \frac{\partial F}{\partial q_s,1} \frac{\partial G}{\partial p_s,1} = 0, \quad (15)
\]

are the Poisson brackets related to the symplectic form \( \omega_0 \).

Quite analogously we can prove that this set of integrals are in involution also with respect to the Poisson brackets \( \{\cdot, \cdot\}_1 \) related to the symplectic form \( \omega_1 \). Thus we have proved that \( \{\mathcal{M}^C, H_0, \omega_0\} \) has \( 2n \) integrals in involution.

The next step is to prove that these \( 2n \) integrals are functionally independent provided the initial ones \( I_k \) are. The independence of \( I_k \) can be expressed by

\[
dI_1 \wedge \ldots \wedge dI_n \equiv \sum_{i_1 < \ldots < i_n} W_{i_1, \ldots, i_n} dz_{i_1} \wedge \ldots \wedge dz_{i_n} \neq 0, \quad (16)
\]

where \( W_{i_1, \ldots, i_n} \) is the minor of order \( n \) of the \( n \times n \) matrix \( W \) with matrix elements

\[
W_{jk} = \frac{\partial I_j}{\partial z_k}, \quad j = 1, \ldots, n, \quad k = 1, \ldots, 2n. \quad (17)
\]
determined by the columns \( 1 \leq i_j < \ldots < i_n \leq 2n \). Here and below we will denote by \( z \) the 2n-component vector with components \( z_i = q_i \) and \( z_{i+n} = p_i \) for \( i = 1, \ldots, n \). In other words the independence of \( I_k \) means that rank \( W = n \).

In the complexified case both the integrals \( I_k^C = I_k^{00} \) and the dynamical variables \( z_j \) become complex-valued. Their independence can be formulated by:

\[
dI_1^C \wedge \ldots \wedge dI_n^C \wedge dI_1^* \wedge \ldots \wedge dI_n^* = (18)
\]

where

\[
\begin{aligned}
W_{j_k}^{11} &= \frac{\partial I_j}{\partial z_k}, \\
W_{j_k}^{12} &= \frac{\partial I_j}{\partial z_k}, \\
W_{j_k}^{21} &= \frac{\partial I_j}{\partial z_k}, \\
W_{j_k}^{22} &= \frac{\partial I_j}{\partial z_k}.
\end{aligned}
\]

Therefore we have to prove now that \( \text{rank} W = 2n \). But due to the analyticity of all \( I_k \) the matrix elements of \( W^{12} \) and \( W^{21} \) vanish and \( W \) becomes a block-diagonal matrix each block being of rank \( n \). The proposition is proved.

**Remark 2** If the transition to action-angle variables is not analytic then Proposition 1 is not directly applicable.

4 Hamiltonian Reductions and Real Hamiltonian forms

In this Section we will show how we associate with each Hamiltonian system \( \mathcal{H} \) a family of RHF. We will do this by using a special type of reductions.

There are several methods to reduce Hamiltonian systems to systems with lower number of degrees of freedom. One of the best known is the reduction by integrals of motion. Indeed, if we constrain our dynamical system by fixing the values of \( p \) integrals of motion \( I_j(q_k, p_k) = \text{const}, \ j = 1, \ldots, p \), then such constraint is compatible with the dynamics and leads to reduced system with \( n - p \) degrees of freedom. Here, we will follow somewhat different route by restricting the dynamics to \( \mathcal{M}_R \) which is the fixed point set of a Cartan-like involutive automorphism \( \tilde{C} \), defined below.

The approach we will follow in this paragraph is inspired by the basic idea of construction of real forms for simple Lie algebras. A basic tool in our construction is the automorphism \( \tilde{C} \), which plays the role of a “complex conjugation operator”.

Let us introduce involutive canonical automorphism \( C \) (i.e. \( C^2 = 1, C^* \omega = \omega \)) on the phase space \( \mathcal{M}^{(n)} \) and on its dual \(^1\)

\[
C \left( \{F,G\} \right) = \{C(F),C(G)\}, \quad C^2 = 1, \quad (20)
\]

\(^1\) In general we should have different notations of \( C \) in these spaces. However, since our phase space is a vector space with some abuse of notations we will use the same letter for both realizations.
where \( F, G \in \mathcal{F}(\mathcal{M}^{(n)}) \) are real analytic functions on \( \mathcal{M}^{(n)} \). The involution acts on them by:
\[
\mathcal{C}(F(p_1, \ldots, p_n, q_1, \ldots, q_n)) = F((C(p_1), \ldots, C(p_n), C(q_1), \ldots, C(q_n)))
\]
(21)

In terms of vector fields \( X, Y \in TM \) and the lifted involution \( TC : TM \rightarrow TM \) we have:
\[
\omega(TC(X), TC(Y)) = \mathcal{C}(\omega(X, Y)), \quad (TC)^2 = \mathcal{I}
\]
(22)
where \( \omega \) is the symplectic form corresponding to the Poisson brackets in (20).

Since \( \mathcal{C} \) has eigenvalues 1 and \(-1\), it naturally splits \( \mathcal{M}^{(n)} \) into two subspaces \( \mathcal{M}^{(n)} = \mathcal{M}^{(n+)} \oplus \mathcal{M}^{(n-)} \) such that
\[
\mathcal{C}X = X \quad \text{for} \quad X \in \mathcal{M}^{(n+)}
\]
\[
\mathcal{C}Y = -Y \quad \text{for} \quad Y \in \mathcal{M}^{(n-)}
\]
(23)
where \( n_{\pm} = \dim \mathcal{M}^{(n_{\pm})} \), \( n = n_{+} + n_{-} \). We also assume that the starting Hamiltonian \( H \) is invariant with respect to \( \mathcal{C} \):
\[
\mathcal{C}(H) = H.
\]
(24)

Equation (20) guarantees that each of the subspaces \( \mathcal{M}^{(n+)} \) and \( \mathcal{M}^{(n-)} \) is a symplectic subspace of \( \mathcal{M}^{(2n)} \). On \( \mathcal{M}^{(n+)} \) and \( \mathcal{M}^{(n-)} \) we have
\[
\omega_{+} = \sum_{k=1}^{n_{+}} dp_{k}^{+} \wedge dq_{k}^{+}, \quad \omega_{-} = \sum_{k=1}^{n_{-}} dp_{k}^{-} \wedge dq_{k}^{-}
\]
for all \( k = 1, \ldots, n_{\pm} \).

In \( \mathcal{M}^{(n)} \) along with \( \mathcal{C} \) we can introduce also the complex conjugation \( \ast \). In this construction obviously \( \mathcal{C} \) commutes with \( \ast \) and their composition \( \tilde{\mathcal{C}} = \mathcal{C} \circ \ast = \ast \circ \mathcal{C} \) is again an involutive automorphism on \( \mathcal{M}^{(2n)} \). Corollary 1

Let \( I_{j}, j = 1, \ldots, n \) be \( n \) integrals of motion in involution of our initial system \( \mathcal{H} \), depending analytically on \( q_{k} \) and \( p_{k} \). Let us denote their extensions to \( \mathcal{M}^{(n)} \) by \( I_{j} = I_{j,0} + iI_{j,1} \). Then both \( I_{j} \) and
\[
\tilde{\mathcal{C}}(I_{j}) = I_{j}^{*}
\]
(26)
are also integrals of motion in involution for the complexified system \( \mathcal{H}^{C} \).

Using eq. (20) it is easy to check that the dynamics generated by a Hamiltonian which is invariant with respect to \( \mathcal{C} \) will have the subspaces \( \mathcal{F}^{+} \) and \( \mathcal{F}^{-} \) of \( \mathcal{C} \)-invariant and \( \mathcal{C} \)-antinvariant functions as invariant subspaces. Moreover \( \mathcal{F}^{+} \) turns out to be also an invariant subalgebra.

The real form \( \mathcal{M}^{(n)}_{R} \) of the phase space is the symplectic (with respect to \( \omega_{0} \)) subspace of \( \mathcal{M}^{(2n)}_{C} \) invariant with respect to \( \tilde{\mathcal{C}} \):
\[
\mathcal{M}^{(n)}_{R} = \mathcal{M}^{(n+)}_{R} \oplus i\mathcal{M}^{(n-)}_{R}
\]
(27)

Indeed any element of \( \mathcal{M}^{(n)}_{R} \) can be represented as:
\[
Z = X + iY \in \mathcal{M}^{(n)}_{R}
\]
(28)
where \( X \) and \( Y \) are real-valued elements of \( \mathcal{M}^{(n+)}_{R} \) and \( \mathcal{M}^{(n-)}_{R} \) respectively. The reality condition means that
\[
\tilde{\mathcal{C}}(Z) = \mathcal{C}(Z^{*}) = \mathcal{C}(X - iY) = X + iY = Z
\]
(29)
where we have made use of Eq. (20).

Here and below by \( F_{R} \) and \( G_{R} \in \mathcal{F}(\mathcal{M}^{(n)}_{R}) \) we denote the restriction of the observables \( F, G \) by restricting their arguments to \( \mathcal{M}^{(n)}_{R} \). Then \( F_{R} \) and \( G_{R} \) satisfy the analog of Eq. (20) with \( \mathcal{C} \) replaced by \( \tilde{\mathcal{C}} \). Due to Eq. (20) their Poisson bracket \( \{ F_{R}, G_{R} \} \in \mathcal{F}(\mathcal{M}^{(n)}_{R}) \) too, i.e. \( \mathcal{F}(\mathcal{M}^{(n)}_{R}) \) becomes a Poisson subalgebra. If we choose the Hamiltonian \( H_{R} \in \mathcal{F}(\mathcal{M}^{(n)}_{R}) \) then
\[
\tilde{\mathcal{C}}(H_{R}) = H_{R}.
\]
(30)

The evolution associated with \( H_{R} \) of the dynamical variable \( F_{R} \):
\[
\frac{dF_{R}}{dt} = \{ H_{R}, F_{R} \},
\]
(31)
defines a dynamics on \( \mathcal{M}^{(n)}_{R} \). Rewriting (31) into its equivalent form:
\[
\omega(X_{H_{R}}, \cdot) = dH_{R} \cdot
\]
(32)
and making use of (22) we see that the vector field \( X_{H_{R}} \) must also satisfy
\[
\tilde{\mathcal{C}}(X_{H_{R}}) = X_{\tilde{C}(H_{R})} = X_{H_{R}}
\]
(33)
on \( \mathcal{M}^{(n)}_{R} \). The symplectic form restricted on \( \mathcal{M}^{(n)}_{R} \) also becomes real and equals
\[
\omega_{R} = \sum_{k=1}^{n_{+}} dp_{k,0}^{+} \wedge dq_{k,0}^{+} - \sum_{k=1}^{n_{-}} dp_{k,1}^{-} \wedge dq_{k,1}^{-}
\]
(34)
where \( p_{k,0}, q_{k,0}^{+}, k = 1, \ldots, n_{+} \) and \( p_{k,1}, q_{k,1}^{-}, k = 1, \ldots, n_{-} \) are the basic elements in \( \mathcal{M}^{(n)}_{R} \).

If \( \mathcal{M}^{(2n)}_{C} \) is endowed with Hamiltonian which is “real” with respect to \( \tilde{\mathcal{C}} \) and whose vector field \( X_{H} \) satisfies (33) then the restriction of the dynamics on \( \{ \mathcal{M}^{(n)}_{R}, \omega_{R}, H_{R} \} \) is well defined and coincides with the dynamics on \( \{ \mathcal{M}^{(2n)}_{C}, \omega_{0}, H_{0} \} \) restricted to \( \mathcal{M}^{(n)}_{R} \).
The complexified equations of motion take the form:

\[
\begin{align*}
\frac{dp_{k,0}^+}{dt} &= -\frac{\partial H_0}{\partial q_{k,0}^+}, \\
\frac{dp_{k,1}}{dt} &= \frac{\partial H_0}{\partial q_{k,1}}, \\
\frac{dp_{k,0}^-}{dt} &= -\frac{\partial H_0}{\partial q_{k,0}^-}, \\
\frac{d q_{k,1}}{dt} &= \frac{\partial H_0}{\partial p_{k,1}}, \\
\frac{d q_{k,0}^+}{dt} &= \frac{\partial H_0}{\partial p_{k,0}^+}, \\
\frac{d q_{k,0}^-}{dt} &= -\frac{\partial H_0}{\partial p_{k,0}^-},
\end{align*}
\] (35)

We shall show that the dynamics on \(\{\mathcal{M}_C^{(2n)}, \omega_0, H_0\}\) reduces naturally to \(\mathcal{M}_R\) which is the fixed point set of \(\check{C}\).

**Proposition 2** Let the Hamiltonian system \(\mathcal{H}_C\) and the involution \(\check{C}\) be as above. Then the second class Dirac constraints

\[
p_{k,1}^+ = 0, \quad q_{k,1}^- = 0, \quad p_{k,0}^- = 0, \quad q_{k,0}^+ = 0
\] (36)

on the subspace \(\mathcal{M}_R\) invariant with respect to \(\check{C}\) are compatible with the dynamics of the complexified Hamiltonian system \(\mathcal{H}_C\). The reduced equations of motion take the form:

\[
\begin{align*}
\frac{dp_{k,0}^+}{dt} &= -\frac{\partial H_R}{\partial q_{k,0}^+}, \\
\frac{dp_{k,1}}{dt} &= \frac{\partial H_R}{\partial q_{k,1}}, \\
\frac{dp_{k,0}^-}{dt} &= -\frac{\partial H_R}{\partial q_{k,0}^-}, \\
\frac{d q_{k,1}}{dt} &= \frac{\partial H_R}{\partial p_{k,1}}, \\
\frac{d q_{k,0}^+}{dt} &= \frac{\partial H_R}{\partial p_{k,0}^+}, \\
\frac{d q_{k,0}^-}{dt} &= -\frac{\partial H_R}{\partial p_{k,0}^-},
\end{align*}
\] (37)

where \(H_R = H_0|_{\mathcal{M}_R}\).

**Proof** Since \(H\) is real analytic function, then

\[H_0(\ldots, p_{k,1}^+, q_{k,1}^+, \ldots) = H_0(\ldots, -p_{k,1}^-, -q_{k,1}^-, \ldots)\]

is an even function of \(p_{k,1}^+\) and \(q_{k,1}^+\). Besides from the condition \(C(H) = H\) it follows, that

\[H_0(\ldots, p_{k,0}^-, q_{k,0}^-, \ldots) = H_0(\ldots, -p_{k,0}^+, -q_{k,0}^+, \ldots)\]

and \(H_0\) is an even function also of \(p_{k,0}^-\) and \(q_{k,0}^-\). Obviously the first derivatives of \(H_0\) with respect to these variables are odd functions and therefore:

\[
\frac{\partial H_0}{\partial q_{k,1}^+}|_{\mathcal{M}_R} = \frac{\partial H_0}{\partial q_{k,0}^+}|_{\mathcal{M}_R} = \frac{\partial H_0}{\partial p_{k,1}^+}|_{\mathcal{M}_R} = \frac{\partial H_0}{\partial p_{k,0}^+}|_{\mathcal{M}_R} = 0.
\] (38)

The real Hamiltonian form is determined by:

\[\mathcal{H}_R = \{\mathcal{M}_R, H_R(p, q), \omega_R\},\]

\[\mathcal{M}_R = \mathcal{M}_+ \oplus i \mathcal{M}_-, \quad H_R(p, q) = H_0(p_k, q_k)|_{\mathcal{M}_R}, \quad \omega_R = \omega_0|_{\mathcal{M}_R} = \sum_{k=1}^{n_+} dp_{k,0}^+ \wedge dq_{k,0}^- - \sum_{k=1}^{n_-} dp_{k,1}^- \wedge dq_{k,1}^+\]

where \(dp_{k,1}^- = -idp_{k,1}^+, dq_{k,1}^- = -idq_{k,1}^+\). The proposition is proved.

Thus we have proved that the equations (35) can be consistently restricted to \(\mathcal{M}_R\) and give rise to a well defined dynamical system with \(n\) degrees of freedom \(\mathcal{H}_R \equiv \{\mathcal{M}_R, \omega_R, H_R\}\) which we call a real Hamiltonian form (RHF) of the initial Hamiltonian system \(\mathcal{H} \equiv \{\mathcal{M}, \omega, H\}\).

Let us now consider the set of observables \(F_R, G_R\) related to our RHF \(\mathcal{H}_R\). They can be obtained from the observables of the complexified system \(\mathcal{H}_C\) by restricting their variables to \(\mathcal{M}_R\). We remind that we are selecting the class of observables which depends analytically on the dynamical variables. This means, that after restricting on \(\mathcal{M}_R\) they satisfy

\[
\left.\frac{\partial F_0}{\partial q_{k,1}^-}\right|_{\mathcal{M}_R} = \left.\frac{\partial F_0}{\partial q_{k,0}^-}\right|_{\mathcal{M}_R} = \left.\frac{\partial F_0}{\partial p_{k,1}}\right|_{\mathcal{M}_R} = \left.\frac{\partial F_0}{\partial p_{k,0}}\right|_{\mathcal{M}_R} = 0
\] (39)

and analogous relations for the partial derivatives of \(G\). If we now calculate the Poisson brackets between two observables \(F_R, G_R\) we easily find that due to eqs. (39) they will simplify to

\[
\{F_R, G_R\}_0 = \sum_{s=1}^{n_+} \left(\frac{\partial F_R}{\partial q_{s,0}} \frac{\partial G_R}{\partial q_{s,1}} - \frac{\partial F_R}{\partial q_{s,1}} \frac{\partial G_R}{\partial q_{s,0}}\right)
\] (40)

Obviously the Poisson brackets (40) correspond to the symplectic form \(\omega_R\).

**Proposition 3** The RHF \(\mathcal{H}_R\) corresponding to a Liouville integrable Hamiltonian system \(\mathcal{H}\) is Liouville integrable.

**Proof** We start with a \(\mathcal{H}\) which has \(n\) integrals in involution \(I_k\) depending analytically on the dynamical variables. The complexification provides us with \(2n\) integrals of motion \(I_k^+\) and \(I_k^-\) which are also in involution. Let us now restrict ourselves to \(\mathcal{M}_R\). To this end we use the involution \(\check{C}\). It is easy to check that \(n\) of the integrals are preserved:

\[
I_{k,R}^+ = \frac{1}{2} \left( I_k + \check{C}(I_k) \right)|_{\mathcal{M}_R}
\] (41)

and become invariant with respect to \(\check{C}\) while the other \(n\) integrals vanish:

\[
I_{k,R}^- = \frac{1}{2} \left( I_k - \check{C}(I_k) \right)|_{\mathcal{M}_R} = 0,
\] (42)

The fact that the integrals \(I_{k,R}^+\) are in involution with respect to the Poisson brackets \(\{\cdot, \cdot\}_R\) follows from (40). The proposition is proved.
Those $I_j$ which have definite $C$-parity will produce real first integrals $I_{j,R}$ for the real form dynamics and those with minus $C$-parity will produce purely imaginary integrals.

**Remark 3** We proved that after restricting $\mathcal{H}^C$ to $\mathcal{M}_R$ the integrals of motion satisfy (42). One may ask whether the inverse statement also holds true. Namely, assume that we restrict $\mathcal{H}^C$ by using simultaneously all $n$ constraints in (42) together with their symplectic conjugate ones. Since $\mathcal{L}_{k,R}$ are all independent on $\mathcal{M}_C$ then such a procedure would lead to a dynamical system with $n$ degrees of freedom. Will this new system coincide with $\mathcal{H}_R$? We believe that the answer to this question is positive, though we do not yet have a rigorous proof of this fact.

If we restrict our dynamical variables on $\mathcal{M}_R$ then only the integrals invariant with respect to $\tilde{C}$ survive.

Let us assume now that we have the complexified system $\mathcal{H}^C$ restricted by (42). Let us now pick a point $m \in \mathcal{M}_R$ which will correspond to the initial condition of our dynamical system with $n$ degrees of freedom. Will this new system coincide with $\mathcal{H}_R$? We believe that the answer to this question is positive, though we do not yet have a rigorous proof of this fact.

As a result the set of constraints (42) split into two orthogonal invariant subspaces.

For some special choices of $H$ it may happen that the dynamics of $\mathcal{H}^C$ and $\mathcal{H}_R$ coincide.

Despite the apparent simplicity of the transition to the real form dynamics it is essentially different from the initial one—the real form dynamical vector field satisfying $\Gamma_R \omega_R = -dH_R$ is generally not even a (locally) Hamiltonian vector field for the initial $\omega$. As a result we may expect that the new and the initial dynamical vector fields will coincide only for very few cases. Conditions for this are settled in the following

**Proposition 4** $\Gamma_R = \Gamma$ iff

i) the Hamiltonian is separable in a sum of two parts depending on as follows: $H = H_+(p_k^+, q_k^+) + H_-(p_j^-, q_j^-)$ where $q_k^+$, $p_k^+$ (resp. $q_j^-$, $p_j^-$) are elements of $\mathcal{M}_+$ (resp. $\mathcal{M}_-$),

ii) $H_-(ip_j^-, iq_j^-) = -H_+(p_j^-, q_j^-)$.

Also, condition i) is equivalent both to the local Hamiltonianity of $\Gamma$ with respect to $\omega_R$ and to the compatibility of $\Gamma$ with $\omega_R$ i.e. $\mathcal{L}_\Gamma \omega_R = 0$.

**Proof** The dynamical vector field satisfying $\Gamma_R \omega_R = -dH_R$ will be:

\[
\Gamma_R = \sum_{k=1}^{n+} \left( \frac{\partial H_R}{\partial p_k^+} \frac{\partial}{\partial q_k^+} + \frac{\partial H_R}{\partial q_k^+} \frac{\partial}{\partial p_k^+} \right) \\
+ \sum_{j=1}^{n-} \left( \frac{\partial H_R}{\partial q_j^-} \frac{\partial}{\partial p_j^-} + \frac{\partial H_R}{\partial p_j^-} \frac{\partial}{\partial q_j^-} \right)
\]

and we have to satisfy:

\[
\frac{\partial H}{\partial q_k^+} = \frac{\partial H_R}{\partial q_k^+}, \quad \frac{\partial H}{\partial q_j^-} = \frac{\partial H_R}{\partial q_j^-} \\
\frac{\partial H}{\partial q_k^+} = \frac{\partial H_R}{\partial q_k^+}, \quad \frac{\partial H}{\partial q_j^-} = \frac{\partial H_R}{\partial q_j^-}.
\]

Comparing the equations from the first and second rows of (43) we obtain that all mixed derivatives of $H$ should vanish:

\[
\frac{\partial^2 H}{\partial q_k^+ \partial q_j^-} = 0, \quad \frac{\partial^2 H}{\partial q_k^+ \partial p_j^-} = 0, \\
\frac{\partial^2 H}{\partial q_k^+ \partial p_j^-} = 0, \quad \frac{\partial^2 H}{\partial q_j^- \partial q_j^-} = 0
\]

which is exactly the separability condition i) of the Hamiltonian. Now ii) part of the Proposition follows trivially from the way we construct $\mathcal{H}_R$.

Due to the closedness of $\omega$ (and $\omega_R$) we have:

\[
\mathcal{L}_\Gamma \omega_R = d(\Gamma \omega_R)
\]

\[= 2 \sum_{j,k} \left( \frac{\partial^2 H}{\partial q_j^- \partial p_j^-} dq_j^+ \wedge dp_j^- + \frac{\partial^2 H}{\partial q_k^+ \partial p_k^+} dq_k^- \wedge dp_k^+ \right)
\]

and vanishing of all mixed derivatives in eq. (45) is the condition for the required compatibility and/or local Hamiltonianity. Since the separability of $H$ is equivalent to the separability of $\mathcal{H}_R$ we have similarly compatibility of $\Gamma_R$ with $\omega$ and local Hamiltonianity of $\Gamma_R$ with respect to $\omega$.

When the conditions of the Proposition 4 are fulfilled our procedure will give us a bi-Hamiltonian description of the initial dynamics with a recursion operator

\[T = \omega^{-1} \circ \omega_R = 1_+ - 1_-
\]

where $1_\pm$ are the identity tensors on $\mathcal{M}_\pm^{(n+z)}$. So, whatever the outcome we gain either new dynamics or a bi-Hamiltonian of the old one.

For instance, if we have a collection of uncoupled harmonic oscillators $H = \sum (p_i^2 + q_i^2)$ and a compatible involution: $C(p_i) = \epsilon_i p_i$, $C(q_i) = \epsilon_i q_i$ with $\epsilon_i = \pm 1$ then we will have $H_R = \sum \epsilon_i (p_i^2 + q_i^2)$ and $\Gamma_R = \Gamma$ i.e. coinciding initial and real form dynamics. The same will be also true for $U(ip_j^-, iq_j^-) = -U(p_j^-, q_j^-)$.

At present, we do not have a receipt how to construct and classify all involutions of $\mathcal{M}$ consistent with a given Hamiltonian. However in many important cases it is possible to provide a number of such non-trivial involutions.

**5 RHF of Completely Integrable systems**

Here we understand the notion of completely integrable systems in a broader sense [10]. We will say that a dynamical system with $n$ degrees of freedom is completely
integrable if we find $2n$ functions $\{I_k, \phi_k\}$, $k = 1, \ldots, n$ such that $I_k$ are integrals of motion, i.e.:
\[ L_I I_k = 0, \quad k = 1, \ldots, n, \tag{47} \]
and $\phi_k$ are nilpotent with respect to the vector field $L_I$ of order 2:
\[ L_I L_I \phi_k = 0, \quad k = 1, \ldots, n. \tag{48} \]

If there is one or more functions of the $\phi$’s which are constants of the motion, the system is said to be superintegrable. We also assume that $\{I_k, \phi_k\}$ introduce local coordinates on our phase space.

Such set of functions $\{I_k, \phi_k\}$ generalize the standard notion of action-angle variables (AAV). While the standard AAV can be introduced only for compact more on a torus, our variables $\{I_k, \phi_k\}$ can be derived also for non-compact dynamics. This is important to our purposes, especially when we analyze how the transition from one RHF to another changes the character of the motion from a compact one and vice versa, see Section 8 below. Therefore from now on, with some abuse of language we will say that $\{I_k, \phi_k\}$ are our AAV.

The complexification renders all $I_k^\pm$ and $\phi_k^\pm$ complex:
\[ I_k^\pm = I_{k,0}^\pm + iI_{k,1}^\pm \quad \text{and} \quad \phi_k^\pm = \phi_{k,0}^\pm + i\phi_{k,1}^\pm \]
and the automorphism $\tilde{C}$ has the form:
\[ \tilde{C}(dI_k^\pm) = \pm(dI_k^\pm)*, \quad \tilde{C}(d\phi_k^\pm) = \pm(d\phi_k^\pm)* \tag{49} \]
The automorphism $\tilde{C}$ obviously satisfies the condition (28). In order to satisfy also (29) we need to assume that $H$ is an even function of all $I_k \in M$. Then the restriction on $M_R$ according to (29) and (49) means restricting all $I_k^\pm, \phi_k^\pm \in M_R$ to be real, while all $I_k^\pm, \phi_k^\pm \in M_-$ become purely imaginary. Then:
\[ H_R = H(I_{1,0}^+, \ldots, I_{n,0}^+, iI_{1,1}^-, \ldots, iI_{n,-1}^-), \]
\[ \omega_R = \sum_{k=1}^n dI_{k,0}^+ \wedge d\phi_{k,0}^+ - \sum_{k=1}^n dI_{k,-1}^- \wedge d\phi_{k,1}^- \tag{50} \]
and obviously we have again a completely integrable Hamiltonian system.

Till the rest of this section we also assume that the Hamiltonian is separable, i.e.
\[ H = \sum_{k=1}^{n_+} h_k^+ (I_k^+) + \sum_{k=1}^{n_-} h_k^- (I_k^-). \tag{51} \]

Obviously the condition (29) requires that $h_k^- (I_k^-)$ must be even functions of $I_k^-$. Another important approach to completely integrable systems is based on the notion of the recursion operator – a (1,1) tensor field with vanishing Nijenhuis torsion. This tensor field reflects the possibility to introduce a second symplectic structure $\omega_1$ on $M$ through:
\[ \omega_1(X, Y) = \frac{1}{2} (\omega(TX, Y) + \omega(X, TY)). \tag{52} \]

In terms of $I_k^\pm, \phi_k^\pm$ the tensor field $T$ and $\omega_1$ can be expressed by:
\[ T = \sum_{k=1}^{n_+} T^+_k + \sum_{k=1}^{n_-} T^-_k, \quad \omega_1 = \sum_{k=1}^{n_+} \omega^+_k + \sum_{k=1}^{n_-} \omega^-_k, \]
\[ T_k^\pm = \zeta^\pm_k (I_k^\pm) \left( dI_k^\pm \otimes \frac{\partial}{\partial I_k^\pm} + d\phi_k^\pm \otimes \frac{\partial}{\partial \phi_k^\pm} \right), \]
\[ \omega^-_k = \zeta^-_k (I_k^-) dI_k^- \wedge d\phi_k^- \tag{53} \]
where $\zeta^\pm_k$ are some functions of $I_k^\pm$, we assume that $H_\omega$ is a real analytic function of their variables.

In order that $\omega_1$ also satisfy eq. (22) it is enough that $C(T) = T$. In particular this means that $\zeta^-_k$ must be even functions of $I_k^-$. If this is so then we can repeat our construction also for $\omega_1$; i.e., we can complexify it and then restrict it onto $M_R$ with the result:
\[ T_R = \sum_{k=1}^{n_+} T^+_{R,k} + \sum_{k=1}^{n_-} T^-_{R,k}, \tag{54} \]
\[ T^-_{R,k} = \zeta^-_k (I_k^-) \left( dI_k^- \otimes \frac{\partial}{\partial I_k^-} + d\phi_k^- \otimes \frac{\partial}{\partial \phi_k^-} \right), \]
\[ \omega_{1,R} = \sum_{k=1}^{n_+} \zeta^+_k (I_k^+) dI_k^+ \wedge d\phi_k^+ - \sum_{k=1}^{n_-} \zeta^-_k (I_k^-) dI_k^- \wedge d\phi_k^- \tag{55} \]
Thus by construction, the restriction to other real forms preserves the Nijenhuis property of $T$ and the condition for double degenerate and nowhere constant eigenvalues. Also it is easy to check that it is preserved by the dynamical flow: $L_\omega T_R = 0$. Due to the fact that existence of recursion operators is equivalent to integrability at least in the non-resonant case, this line of argumentation gives us another instrument to treat the integrability of real forms.

The separability of $H$ looks rather restrictive condition. However, all integrable systems obtained by reducing a soliton equation (like, e.g. the nonlinear Schrödinger equation) on its $N$-soliton sector are separable. Finite-dimensional systems allowing Lax pairs like Toda chains, Calogero-Moser systems etc. also possess this property, see eq. (70) below.

6 Examples

We illustrate our construction by several paradigmatic examples which include several types of Toda chain models and Calogero-Moser models.

Example 1 Toda chain related to the $sl(n, \mathbb{C})$ algebra. We consider simultaneously the conformal and the affine case by introducing the parameter $c_0$ which takes two values: $c_0 = 0$ (conformal case) and $c_0 = 1$ (affine case).
\[ H_{TC} = \sum_{k=1}^{n} \frac{p_k^2}{2} + \sum_{k=1}^{n-1} e^{q_{k+1} - q_k} + c_0 e^{q_1 - q_n}. \]
\[
\omega = \sum_{k=1}^{n} dp_k \wedge dq_k. \tag{55}
\]

We choose the involution as:
\[
\mathcal{C}(p_k) = -p_k, \quad \mathcal{C}(q_k) = -q_k. \tag{56}
\]

where \( \bar{k} = n + 1 - k \). We also introduce new symplectic coordinates adapted to the action of \( C \):
\[
p_{\bar{k}}^+ = \frac{p_k - p_{\bar{k}}}{\sqrt{2}}, \quad q_{\bar{k}}^+ = \frac{q_k - q_{\bar{k}}}{\sqrt{2}}, \tag{57}
\]
\[
p_{\bar{k}}^- = \frac{p_k + p_{\bar{k}}}{\sqrt{2}}, \quad q_{\bar{k}}^- = \frac{q_k + q_{\bar{k}}}{\sqrt{2}}, \quad k = 1, \ldots, r = [n/2]
\]

where \( n = 2r + r_0 \) with \( r_0 = 0 \) or \( 1 \); for \( r_0 = 1 \) we have to add also: \( \bar{p} = p_{r+1}, \bar{q} = q_{r+1} \). These coordinates are such that
\[
\mathcal{C}(p_{\bar{k}}^+) = \pm q_{\bar{k}}^+, \quad \mathcal{C}(q_{\bar{k}}^+) = \pm q_{\bar{k}}^-, \mathcal{C}(\bar{p}) = -\bar{p}, \quad \mathcal{C}(\bar{q}) = -\bar{q}. \tag{58}
\]

As a result we obtain the following real forms of the TC model: i) for \( n = 2r + 1 \):
\[
H_{TC1} = \frac{1}{2} \sum_{k=1}^{r} \left( (p_k^+)^2 - (p_k^-)^2 \right) - \frac{1}{2} (p_{\bar{r}+1})^2 + \frac{1}{2} \sum_{k=1}^{r-1} e^{q_{k+1}^+ - q_k^- + \sqrt{2} \cos \frac{q_{k+1} - q_k}{\sqrt{2}}} \right) + 2e^{-q_r^+ / \sqrt{2}} \cos \left( q_{r+1}^- - q_r^+ / \sqrt{2} \right) \tag{59}
\]
\[
\omega_R = \sum_{k=1}^{r} dp_k^+ \wedge dq_k^- - \sum_{k=1}^{r+1} dp_k^- \wedge dq_k^+.
\]

ii) for \( n = 2r \):
\[
H_{TC2} = \frac{1}{2} \sum_{k=1}^{r} \left( (p_k^+)^2 - (p_k^-)^2 \right) + e^{-\sqrt{2}q_{\bar{r}}^+} + \frac{1}{2} \sum_{k=1}^{r-1} e^{q_{k+1}^+ - q_k^- + \sqrt{2} \cos \frac{q_{k+1} - q_k}{\sqrt{2}}} \right) \tag{60}
\]
\[
\omega_R = \sum_{k=1}^{r} dp_k^+ \wedge dq_k^- - \sum_{k=1}^{r} dp_k^- \wedge dq_k^+.
\]

These models are generalizations of the well known Toda chain models associated to the classical Lie algebras \([13]\); indeed if we put \( q_k = 0 \) and \( p_k = 0 \) we find that \([14]\) goes into the \( B_r \) TC while \([13]\) provides the \( C_r \) TC.

**Example 2** The real Hamiltonian forms for the Calogero–Moser systems (CMS) \([16]\). The CMS corresponding to the root systems of \( A, B, C, D \) and \( BC \)-series \([17]\) are defined by Hamiltonians of the type:
\[
H_{CMS} = \frac{1}{2} \sum_{j=1}^{n} p_j^2 + U(q) \tag{61}
\]

with:
\[
U = \begin{cases} 
\frac{g_2 V_n}{2}, & \text{for } A_{n-1} \\
\frac{g_2 (V^2 + V^+)}{2} + \frac{g_1^2 V_1 + g_2^2 V_2}{2}, & \text{for } BC_n.
\end{cases}
\]

Here
\[
V_n = \sum_{j<k \leq n} v(q_j \pm q_k), \quad V_1 = \sum_{j<k \leq n} v(q_j), \quad V_2 = \sum_{j<k \leq n} v(2q_j), \tag{62}
\]

and the function \( v(x) \) is one of the following:
\[
v(q) = \frac{1}{q^2}, \quad \frac{1}{\sin^2 q}, \quad \frac{1}{\sinh^2 q}, \quad \frac{1}{q^2 + \omega q^2}, \quad \varphi(q) \tag{63}
\]

where \( \varphi(q) \) is the Weierstrass function.

The \( BC_n \) case contains in itself the CMS for the algebras \( B_n, C_n \) and \( D_n \); they are obtained by putting \( g_2 = 0 \), \( g_1 = 0 \) and \( g_1 = g_2 = 0 \) respectively.

All these models are invariant under the involution \([15]\). For convenience we again use the coordinates \([15]\) together with the following complex coordinates
\[
z_j = \frac{1}{\sqrt{2}} \left( q_j^+ + i q_j^- \right), \quad z_j^* = \frac{1}{\sqrt{2}} \left( q_j^+ - i q_j^- \right), \tag{64}
\]

\( k = 1, \ldots, r \).

In order to obtain the Hamiltonian of the RHF of the CMS we have to express \( H_{CMS} \) in the new coordinates and assume that \( \bar{p}, \bar{q}, \bar{p} \) and \( \bar{q} \) are purely imaginary and then calculate its real part. We shall denote the imaginary parts of these variables by the same letter but without tilde and so all tilde-less variables will be real. As a result:
\[
Re \sum_{j=1}^{n} \frac{p_j^2}{2} = \frac{1}{2} \sum_{k=1}^{r} (p_k^+)^2 - \frac{1}{2} \sum_{k=1}^{r} (p_k^-)^2 - \frac{1}{2} r_0 p_0^2, \tag{65}
\]
\[
Re V_n^1 = 2 \sum_{j=1}^{r} v(z_j) - r_0 v(q), \tag{66}
\]
\[
Re V_n^2 = 2 \sum_{j=1}^{r} v(2z_j) - r_0 v(2q), \tag{67}
\]
\[
Re V_n^0 = 2 \sum_{j<k \leq r} \left[ v(z_j - z_k) + v(z_j + z_k^*) \right] + \sum_{k=1}^{r} v(\sqrt{2}q_k^*) + 2r_0 \text{Re} \sum_{j\leq r} v(z_j - iq), \tag{68}
\]
\[
Re V_n^2 = 2 \sum_{j<k \leq r} \left[ v(z_j + z_k) + v(z_j - z_k^*) \right] - \sum_{k=1}^{r} v(\sqrt{2}q_k^*) + 2r_0 \text{Re} \sum_{j\leq r} v(z_j + iq). \tag{69}
\]

To illustrate the form of the new Calogero-Moser potentials we note that:
\[
\frac{1}{\sinh^2(x + iy)} = \frac{(\sin x \cos y)^2 - (\cos x \sin y)^2}{((\sin x)^2 + (\sin y)^2)^2}, \tag{70}
\]
\[
\frac{1}{\sin^2(x + iy)} = \frac{(\sinh x \cos y)^2 - (\cos x \sin y)^2}{((\sinh x)^2 + (\sin y)^2)^2}. \tag{71}
\]
Together with
\[ \omega_r = \sum_{k=1}^{r} (dp^+_k \wedge dq^+_k - dp^-_k \wedge dq^-_k) - r_0 dp \wedge dq \]  
(64)

they define the real form dynamics which is obviously not confined to the standard Calogero-Moser models.

More explicitly:

for \( n = 2r + 1 \) and \( \mathfrak{g} \simeq \mathfrak{a}_{n-1} \):

\[
H_{\text{CM,R}} = \frac{1}{2} \sum_{k=1}^{r} [(p^+_k)^2 - (p^-_k)^2] - \frac{1}{2}(p^-_{r+1})^2 + \\
+ 2g^2 \sum_{i<j}^{r} \text{Re} \left[ v(z_i - z_j) + v(z_i + z_j^*_{r+1}) \right] + \\
+ g^2 \sum_{j=1}^{r} v(\sqrt{2}q^+_j) + 2g^2 \sum_{j=1}^{r} \text{Re} v(z_i - iq^-_{r+1}).
\]

for \( n = 2r \) and \( \mathfrak{g} \simeq \mathfrak{a}_{n-1} \):

\[
H_{\text{CM,R}} = \frac{1}{2} \sum_{k=1}^{r} [(p^+_k)^2 - (p^-_k)^2] + g^2 \sum_{j=1}^{r} v(\sqrt{2}q^+_j) + \\
+ 2g^2 \sum_{i<j}^{r} \text{Re} \left[ v(z_i - z_j) + v(z_i + z_j^*) \right].
\]

for \( n = 2r + 1 \) and \( \mathfrak{g} \simeq \mathfrak{b}_n \):

\[
H_{\text{CM,R}} = \frac{1}{2} \sum_{k=1}^{r} [(p^+_k)^2 - (p^-_k)^2] - \frac{1}{2}(p^-_{r+1})^2 + \\
+ g^2 \sum_{j=1}^{r} \left[ v(\sqrt{2}q^+_j) - v(\sqrt{2}q^-_j) \right] + \\
+ 2g^2 \sum_{i<j}^{r} \text{Re} \left[ v(z_i - z_j) + v(z_i + z_j^*) \right] + \\
+ v(z_i + z_j^*) + v(z_i + z_j) + v(z_i - z_j^*) + \\
+ 2g^2 \sum_{j=1}^{r} \text{Re} v(z_j) + 2g^2 \sum_{j=1}^{r} \text{Re} v(2z_j) + \\
+ 2g^2 \sum_{j=1}^{r} \text{Re} v(z_j) + 2g^2 \sum_{j=1}^{r} \text{Re} v(2z_j).
\]

Note that: \( v(\pm) = -v(\pm) \).

Example 3 In the case of involution \( C_2 = S_{e_1-e_2} \):

\[ C_2(q_1) = q_2, \ C_2(q_2) = q_1, \ C_2(p_1) = p_2, \ C_2(p_2) = p_1, \]

we obtain for \( \mathfrak{g} \simeq \mathfrak{b}_n \):

\[
H_{\text{CM,R}} = \frac{1}{2} \left[ (p^+_1)^2 - (p^-_1)^2 + \sum_{k=3}^{n} (p^+_k)^2 \right] + \\
+ g^2 \left[ 2\text{Re} v(z_1) + \sum_{j=3}^{n} \text{Re} v(q_j) \right] + \\
+ g^2 \left\{ \sum_{j=3}^{n} \text{Re} \left[ v(z_1 - q^*_j) + v(z_1 + q^*_j) \right] - \\
- v(\sqrt{2}q^-_1) + v(\sqrt{2}q^*_1) + \\
+ \sum_{3 \leq k < j} \left[ v(q_k - q_j) + v(q_k + q_j) \right] \right\} + \\
+ g^2 \left[ 2\text{Re} v(2z_1) + \sum_{j=3}^{n} \text{Re} v(2q_j) \right] + \\
\]

Example 4 In the case of involution \( C_3 = -\mathbb{I} \):

\[ C_2(q_k) = -q_k, \ C_2(p_k) = -p_k, \]

\[ q_k = q_k, \ p_k = p_k, \ \dim M_\mathfrak{m} = 2n. \]

We obtain for Toda chains with the algebra \( \mathfrak{a}_{n-1} \simeq \mathfrak{sl}(n) \):

\[
H_{\text{TC}} = \frac{1}{2} \sum_{k=1}^{n} p_k^2 + \sum_{k=1}^{n-1} e^{\beta(q_k)} + c_0 e^{\beta(q_n)},
\]

where \( c_0 = 0 \) stands for conformal TC and \( c_0 = 1 \) for affine TC. Now all \( p_k \) and \( q_k \) become purely imaginary.

We choose also \( \beta = i\beta_0 \). As a result we obtain Toda chain with purely imaginary interaction constant.

Similarly, for CMS we obtain:

A) If \( v(q) = 1/q^2 \) or \( v(q) = 1/q^2 + \omega^2 q^2 \) then we obtain:

\[ H_{\text{CM,R}} = -H, \]

which is equivalent to \( t \leftrightarrow -t \).

B) If \( v_2(q) = a^2/\sin^2(aq) \) and \( v_3(q) = a^2/\sinh^2(aq) \) then the real form dynamics is obtained by the exchange:

\[ v_2(q) \leftrightarrow -v_3(q), \quad t \leftrightarrow -t. \]

C) If \( v_4(q) = a^2\varphi(aq|\omega_1, \omega_2) \) then the real form dynamics is obtained by the exchange:

\[ v_4(q) \leftrightarrow -v_4(q), \quad t \leftrightarrow -t. \]

where \( v_4(q) = -a^2\varphi(aq|i\omega_1, i\omega_2) \).
Remark 4 Several of the RHF of CMS have been obtained earlier by Calogero [18] using the so-called ‘duplication procedure’. Our results above show that each ‘duplication’ is related to a Cartan-like automorphism of the relevant Lie algebra. This fact can be used to classify all inequivalent RHF of CMS.

Example 5 An example from general relativity: transition from SO(3) to SO(2, 1) symmetry.

Recall that the geodesic Schwarzschild flow, corresponding to a metric $g = g_{ij} dx_i dx_j$ on $\mathcal{M}$, can be viewed as the flow, generated by the Hamiltonian field $X_H$ with $H = \frac{1}{2} y^i p_i$. 

Several matrix $y_i$ are conjugated to $x_i$'s coordinates on $T^*\mathcal{M}$.

For example, the geodesic flow for the Schwarzschild metric

$$ g_1 = \epsilon_1 \left( \frac{r^2 - 2MG}{r c} \right) dr^2 + \epsilon_2 \left( \frac{d\vartheta^2 + \sin^2 \vartheta d\varphi^2}{r^2} \right), $$

where $\epsilon_1 = \pm 1$, $\epsilon_2 = \pm 1$, is described by the (completely integrable) Hamiltonian

$$ \mathcal{H}_1 = \frac{1}{4} \left[ \epsilon_1 \left( \frac{r^2 - 2MG}{r c} p_i^2 - \frac{r^2 - 2MG}{r c} p_i p_i \right) + \epsilon_2 \frac{1}{r^2} \left( p_\vartheta^2 + \frac{1}{\sin^2 \vartheta} p_\varphi^2 \right) \right]. $$

(65)

The complexification and real projection procedure leads to the following Hamiltonian

$$ \mathcal{H}_2 = \frac{1}{4} \left[ \epsilon_1 \left( \frac{r^2 - 2MG}{r c} p_i^2 - \frac{r^2 - 2MG}{r c} p_i p_i \right) - \epsilon_2 \frac{1}{r^2} \left( p_\vartheta^2 + \frac{1}{\sin^2 \vartheta} p_\varphi^2 \right) \right], $$

which is (still completely integrable and) is associated with the metric

$$ g_2 = \epsilon_1 \left( \frac{r^2 - 2MG}{r c} dt^2 - \frac{r^2 - 2MG}{r c} dr^2 - \epsilon_2 r^2 \left( d\vartheta^2 + \sin^2 \vartheta d\varphi^2 \right) \right), $$

(66)

solution of vacuum Einstein field equations [19,20].

The above notation for coordinates might be misleading because, in $g_1$ and $H_1$, $r \in [0, \infty[, \vartheta \in [-\pi, \pi[, \varphi \in [0, 2\pi]$ denote spherical coordinates, while, in $g_2$ and $H_2$, $r \in [0, \infty[, \vartheta \in R, \varphi \in [0, 2\pi]$ denote pseudo-spherical coordinates.

The 2-dimensional surfaces endowed with metric $g_2$ restricted by $(r, t = \text{const})$ may be identified with one of the sheets of the two-sheeted space-like hyperboloid. They are also known as pseudo-spheres.

The pseudo-sphere is a surface with constant negative Gaussian curvature $\mathcal{R} = -1/r^2$. It can be globally embedded in a 3-dimensional Minkowskian space. Let $x_1, x_2, x_3$ denote the coordinates in the Minkowskian space, where the separation from the origin is given by $y^2 = -y_1^2 + y_2^2 + y_3^2$. These coordinates are connected to the pseudo-spherical coordinates $(r, \vartheta, \varphi)$ by:

$$ y_1 = r \cos \vartheta, \quad y_2 = r \sin \vartheta \cos \varphi, \quad y_3 = r \sin \vartheta \sin \varphi. $$

The equation $y^2 = -r^2$, i.e. the locus of points equidistant from the origin, specifies a hyperboloid of two sheets intersecting the $y_1$ axis at the points $\pm r$ called poles in analogy with the sphere. Either sheet (say the upper sheet) model an infinite spacelike surface without a boundary; hence, the Minkowski metric becomes positive definite (Riemannian) upon it. This surface has constant Gaussian curvature $(\mathcal{R} = -1/r^2)$, and it is the only simply connected surface with this property. Other embeddings of the pseudo-sphere in the 3-dimensional Euclidean space are also available, for example it can be regarded as the 2-dimensional surface generated by the tractrix, but they are not global.

It is worth noting that metrics $g_1$ and $g_2$ are so(3)-invariant and so(2, 1)-invariant^2, respectively, and that geodesic flows, corresponding to the model Ricci-flat metrics, associated with 3-dimensional Killing algebras, are integrable. To see that one may observe that, for instance, Hamiltonian $\mathcal{H}_2$ possesses five independent first integrals

$$ \mathcal{H}_2, \quad p_\vartheta, \quad p_\varphi^2 + \frac{1}{\sin^2 \vartheta} p_\varphi^2, \quad I_1, \quad I_2 $$

where $I_1$ and $I_2$ are generators of a noncommutative two-dimensional subalgebra of so(2, 1), for example

$$ I_1 = \left[ \left( 1 + \sqrt{2} \right) \cos \varphi + \sin \varphi \right] p_\varphi + \left[ 1 + \sqrt{2} \right] \coth \vartheta \left( \cos \varphi - \left( 1 + \sqrt{2} \right) \sin \varphi \right] p_\varphi $$

$$ I_2 = \sqrt{2} \left[ \cos \varphi + \sin \varphi \right] p_\varphi + \left[ 2 + \sqrt{2} \right] \coth \vartheta \left( \cos \varphi - \sin \varphi \right) p_\varphi. $$

(67)

The 5 first integrals span a rank 3 Lie algebra $\mathcal{A}$, and since $\text{rank} \ A + \dim \mathcal{A} = \dim T^*\mathcal{M}$ and $\text{rank} \ A < \dim \mathcal{A}$ the system is noncommutatively integrable in the sense [22,23].

Geodesic flows corresponding to the metrics invariant for a 3-dimensional Lie algebra are discussed in [20]. Note also that the above proposition is no more valid for the geodesic flow of Ricci-flat metrics with nonextendable two-dimensional Killing algebras.

7 Lax operators

It is well known that a number of completely integrable systems admit Lax representation. By it we mean the existence of two matrices $L(p, q)$ and $M(p, q)$ depending

\^2 In the pseudo-spherical coordinates, the so(2, 1) Lie algebra $[X_1, X_2] = X_3, \quad [X_2, X_3] = -X_1, \quad [X_3, X_1] = -X_2$, is spanned by $X_1 = \sin \varphi \partial_\varphi + \cos \varphi \coth \vartheta \partial_\vartheta, \quad X_2 = -\cos \varphi \partial_\vartheta + \sin \varphi \coth \vartheta \partial_\varphi, \quad X_3 = \partial_\varphi$. [21].
explicitly on the dynamical variables and such that the 
Lax equation
\[
\frac{dL}{dt} = [L, M]
\] (69)
is equivalent to the corresponding equations of motion of \( H \). Let us also remind that from (62) there follows imme-
diately that the eigenvalues \( \zeta \) of \( L \) are integrals of 
the motion in involution. One can use also as such

\[ I_k = \text{tr} L^k (p, q) = \sum_{s=1}^n c_s^k, \quad k = 1, \ldots, n, \] (70)

and as a rule the Hamiltonian \( H \) is a linear combination of
\( I_k \)'s; for example, for the Toda chain and for the CMS \( H = 2 I_2 \).

If the matrices \( L \) and \( M \) are analytic (meromorphic) 
functions of \( p_k \) and \( q_k \) then obviously these properties will 
hold true also for the integrals \( I_k \). The analytic properties 
of \( \zeta \) as functions of \( p_k \) and \( q_k \) require additional consid-
erations. Indeed, \( \zeta \) are roots of the corresponding charac-
teristic equation which is of order \( n \) so the mapping from 
\( p_k \) and \( q_k \) to \( \zeta \) may have essential singularities.

The Lax representation ensures also the separability of 
all \( I_k \) (including \( H \)) in terms of \( \zeta \). For some of the best 
known cases like for the Toda chain, the matrices \( L \) and 
\( M \) take values in the normal real form of some simple Lie 
and \( p_k \) complex-valued. 

\[ L \rightarrow \mathcal{L} = L_0 + i L_1, \quad M \rightarrow \mathcal{M} = M_0 + i M_1, \quad L, M \in \mathfrak{g}^\mathbb{C}. \]

Note however, that the complexified Lax equation
\[
\frac{d\mathcal{L}}{dt} = [\mathcal{L}, \mathcal{M}],
\] (71)
can again be written down in terms of purely real Lax 
matrices with doubled dimension:
\[
\frac{d\mathbf{L}}{dt} = [\mathbf{L}, \mathbf{M}], \quad \mathbf{L} = \begin{pmatrix} L_0 & L_1 \\ -L_1 & L_0 \end{pmatrix}, \quad \mathbf{M} = \begin{pmatrix} M_0 & M_1 \\ -M_1 & M_0 \end{pmatrix}.
\] (72)

This fact we will use below when we discuss general-
izations of our approach.

Let us now consider the Lax representation for the 
Toda chain related to the simple Lie algebra \( \mathfrak{g} \) with rank 
\( n \):
\[
L_{TC} = \sum_{k=1}^n p_k H_k + \sum_{k=1}^n a_k (E_{\alpha_k} + E_{-\alpha_k}) + c_0 a_0 (E_{\alpha_0} + E_{-\alpha_0}),
\]
\[
M_{TC} = \sum_{k=1}^n a_k (E_{\alpha_k} - E_{-\alpha_k}) + c_0 a_0 (E_{\alpha_0} - E_{-\alpha_0}),
\]
where \( \alpha_k \) is the set of simple roots of \( \mathfrak{g} \), \( \alpha_0 \) is the minimal 
root of \( \mathfrak{g} \),
\[
a_k = \frac{1}{2} \exp((q, \alpha_k)),
\]
and \( c_0 \) was introduced in (63) above. By \( E_\alpha \) and \( H_k \) above 
we denote the Cartan-Weyl generators of \( \mathfrak{g} \); they satisfy 
the commutation relations:
\[
[H_k, E_\alpha] = (\alpha, e_k) E_\alpha, \quad [E_\alpha, E_{-\alpha}] = H_\alpha, \quad [E_{\alpha}, E_{\beta}] = N_{\alpha,\beta} E_{\alpha+\beta},
\] (75)
where \( \alpha \) and \( \beta \in \Delta \) are any two roots of \( \mathfrak{g} \) and \( N_{\alpha,\beta} = 0 \) 
if \( \alpha + \beta \not\in \Delta \).

The involution \( C \) induces an involutive automorphism 
\( C \) in the algebra \( \mathfrak{g} \). Indeed, both \( p \) and \( q \) can be viewed 
as vectors in the root space \( \mathbb{E}^\circ \cong \mathfrak{h}^* \) which is dual to 
the Cartan subalgebra \( \mathfrak{h} \subset \mathfrak{g} \). Besides, \( C \) must preserve 
the Toda chain Hamiltonian:
\[
H_{TC} = \frac{1}{2} \text{tr} L_{TC}^2 = \frac{1}{2} \sum_{k=1}^n p_k^2 + \sum_{k=1}^n a_k^2 + c_0^2 q_0^2.
\] (76)
This means that \( C \) in the conformal (resp. affine) case must 
preserve the system of simple (resp. admissible) roots of \( \mathfrak{g} \). 
This allows one to associate with the involutive automor-
phism \( C \) an involutive automorphism \( C^\# \) of the algebra \( \mathfrak{g} \). 
Obviously, if \( C \) is defined on \( \mathcal{M} \) by
\[
C(p_k) = \sum_{s=1}^n c_{ks} p_s, \quad C(q_k) = \sum_{s=1}^n c_{ks} q_s,
\] (77)
where \( c_{ks} \) are such that \( \sum_{s=1}^n c_{ks} c_{sm} = \delta_{km} \) then the 
action of \( C^\# \) on \( \mathfrak{h} \) can be determined by duality as:
\[
C^\#(H_k) = H_{C(\alpha_k)} = \sum_{s=1}^n c_{ks} H_s.
\] (78)
On the root vectors \( E_\alpha \) the automorphism \( C^\# \) acts as follows:
\[
C^\#(E_\alpha) = n_\alpha E_{C^\#(\alpha_\alpha)}, \quad n_\alpha = \pm 1.
\] (79)

An well known fact is that the subgroup of the 
automorphism group preserving \( \mathfrak{h} \) is determined by \( \text{Ad}_\mathfrak{h} \otimes \mathfrak{w}_\mathfrak{g} \otimes \mathfrak{v}_\mathfrak{g} \), where \( \text{Ad}_\mathfrak{g} \) is the subgroup of inner automor-
phisms by elements of the Cartan subgroup, \( \mathfrak{w}_\mathfrak{g} \) is the 
Weyl group and \( \mathfrak{v}_\mathfrak{g} \) is the group of outer automorphisms. 
\( \mathfrak{v}_\mathfrak{g} \) is isomorphic to the symmetry group of the Dynkin 
diagram of \( \mathfrak{g} \).

Since the involution \( C \) for the conformal Toda chain 
must preserve the set of simple roots of \( \mathfrak{g} \) it must be related 
to a symmetry of the Dynkin diagram; therefore \( C^\# \) must 
correspond to an outer automorphism of \( \mathfrak{g} \). For the affine 
Toda chains \( C^\# \) must be related to a symmetry of the 
extended Dynkin diagram which allows for a larger set of 
choices for \( C^\# \). These symmetries have been classified in [24].

**Remark 5** The involution \( C^\# \) dual to \( C \) in eq. (64) is the 
outer automorphism of \( sl(n) \).
Analogously we consider the Lax representation of the Calogero-Moser models is of the form [17]:

\[ L(p, q) = \sum_{j=1}^{n} p_j H_j + i \sum_{\alpha \in \Delta} g_\alpha x((q, \alpha)) E_\alpha, \]  
\[ M(p, q) = \sum_{j=1}^{n} \zeta_j H_j + \sum_{\alpha \in \Delta} g_\alpha y((q, \alpha)) E_\alpha, \]

(80)

(81)

The constant \( g_\alpha \) depends only on the length of the root \( \alpha \). The three functions \( x(q) \), \( y(q) \) and \( z(q) \) satisfy a set of functional equations:

\[
y(q) = -x'(q), \quad z(\xi) = \frac{x''(\xi)}{2x(\xi)}, \quad \]  
\[
x(\xi)x'(\eta) - x(q')(\xi) = x(\xi + \eta)[z(\xi) - z(\eta)], \]  

(82)

(83)

The Hamiltonian \( H = \frac{1}{2} \text{tr} L^2 \) and the function \( v(q) \) are related to them by:

\[
v(q) = -x(q)x(-q). \]

The solutions to these equations are given by [16-18]:

\[
x(\xi) = \begin{cases} 
\frac{1}{\xi}, & I \\
\frac{a \coth(a\xi)}{a \sinh^{-1}(a\xi)}, & II \\
\frac{a \cotan(a\xi)}{a \sin^{-1}(a\xi)}, & III \\
\frac{a \sin(a\xi)}{a \sin(a\xi)}, & IV \\
\end{cases} \]

(84)

then the corresponding \( v(\xi) \) provide the choices in [84].

The involution \( C^\# \) induces a Cartan involution \( \sim \) on \( g^C \) by \( C(Z) = -C(Z') \) has all the properties of Cartan involution. As a result the invariance condition with respect to \( \sim \) restricts to a real form of \( g \). The invariance condition for \( L \) has the form:

\[
C(L(C^\#(p), C^\#(q), g) = L(p, q, -g). \]  

(85)

For the case of the example above with \( g \simeq sl(n) \) and \( x(q) = -x(-q) \) this can be easily shown by realizing that \( C(X) \) can be written in the form \( C(X) = TAX^{-1} \) where \( T = \sum_{k=1}^{n} E_{k,k} \). One can check that [85] and an analogous relation on \( M(p, q, g) \) leave the Lax representation invariant. Compare this with Mikhailov reduction group [25]. In this example we miss the spectral parameter, but we also have the interaction constant \( g \) and [85] involves non-trivial action also on \( g \).

The substantial difference as compare to the Toda chain case is that the Calogero-Moser Hamiltonian is invariant with respect to the Weyl group of \( g \) as well as with respect to the group of outer automorphisms of \( g \). Therefore any involutive element of \( W_\alpha \otimes V_\alpha \) can be used to construct a RHF of the CMS. Obviously two such RHF’s will be equivalent if the corresponding automorphisms \( C_1 \) and \( C_2 \) belong to the same conjugacy class of \( W_\alpha \).

This means that the number of inequivalent choices for the involution \( C \) and therefore, the number of inequivalent RHF of the Calogero-Moser systems is much bigger. To classify all of them one has to consider the equivalence classes of \( W(g) \) and pick up just one element from each class of second order elements. It would be also natural to relate to each Satake diagram of \( g \), or a subalgebra of \( g \) a RHF of CMS. A detailed study will be reported elsewhere.

The Cartan subalgebra \( h \) and the algebra \( g \), just like \( M \), can be splitted into direct sums:

\[
h = h_+ \oplus h_-, \quad g = g_+ \oplus g_-, \]

(86)

compatible with the involution \( C^\# \); i.e.:

\[
C^\#(X) = X, \quad \text{for any } X \in h_+, \quad C^\#(X) = -X, \quad \text{for any } X \in g_+. \]

If we compose \( C^\# \) with \(-1\) we obtain the Cartan involution \( \bar{C}^\# \) which selects a real form of the algebra \( g_\mathbb{R} \).

8 Dynamics of the Toda chain and its RHF

In this Section on the example of the Toda chains, we briefly discuss how the two basic steps in constructing the RHF’s may affect the dynamical regimes of the Hamiltonian systems. These two steps are:

a) complexification and,

b) imposing the involution \( \bar{C} \).

The dynamical regimes of the CTC were studied recently from the point of view of their applications to the adiabatic N-soliton interactions [11]. It was already known that CTC has a much richer class of dynamical regimes than the real TC. This shows that step a) (the complexification) changes drastically the character of the dynamics of out initial Hamiltonian system.

Indeed, it is well known [26,27] that the solutions of the conformal Toda chains are parametrized by the eigenvalues \( \zeta_j \) and the first components \( r_j \) of the normalized eigenvectors of the Lax matrix:

\[
L w_j = \zeta_j w_j, \quad r_j = w_j^{(1)}, \]

(87)

(88)

For the Toda chain related to the algebra \( sl(n) \) these solutions take the form:

\[
q_1(t) = \ln A_1(t), \quad A_1(t) = \sum_{j=1}^{n} r_j^2 e^{-2\zeta_j t}, \]

(89)

(90)

For the Toda chain related to the algebra \( sl(n) \) these solutions take the form:

\[
q_1(t) = \ln A_1(t), \quad A_1(t) = \sum_{j=1}^{n} r_j^2 e^{-2\zeta_j t}, \]

(87)

(88)

For the Toda chain related to the algebra \( sl(n) \) these solutions take the form:

\[
q_1(t) = \ln A_1(t), \quad A_1(t) = \sum_{j=1}^{n} r_j^2 e^{-2\zeta_j t}, \]

(87)

(88)

For the Toda chain related to the algebra \( sl(n) \) these solutions take the form:

\[
q_1(t) = \ln A_1(t), \quad A_1(t) = \sum_{j=1}^{n} r_j^2 e^{-2\zeta_j t}, \]

(87)

(88)
where $W_{j_1,\ldots,j_k}$ is the Wanderinge determinant:

$$W_{j_1,\ldots,j_k} = \det \begin{pmatrix} 1 & 1 & \ldots & 1 \\ \zeta_{j_1} & \zeta_{j_2} & \ldots & \zeta_{j_k} \\ \vdots & \vdots & \ddots & \vdots \\ \zeta_{j_1}^{k-1} & \zeta_{j_2}^{k-1} & \ldots & \zeta_{j_k}^{k-1} \end{pmatrix}. \quad (91)$$

It is well known that for the real Toda chain:
1) all $\zeta_j$ are real and pair-wise different;
2) all $r_j$ are also real $[28]$. This ensures that $A_k(t)$ is positive for all $t$. In addition one can evaluate the asymptotic behavior of $q_k(t)$ for large $|t|$. If we assume that the eigenvalues $\zeta_k$ satisfy the sorting condition:

$$\zeta_1 > \zeta_2 > \ldots > \zeta_n, \quad (92)$$

then we get the result:

$$\lim_{t \to \pm \infty} (q_k(t) - v_k^\pm t) = \beta_k^\pm, \quad (93)$$

$$v_k^- = -2\zeta_k, \quad v_k^+ = -2\zeta_{n+1-k}; \quad (94)$$

for the constants $\beta_k^\pm$ one can derive explicit expressions in terms of $\zeta_j$.

If we interpret $q_k(t)$ as the trajectory of the $k$-th particle then $2\zeta_j$ characterize their asymptotic velocity. The property 1) above means that the (real) Toda chain allows only for (non-compact) asymptotically free motion of the particles.

The set of coefficients $\{\zeta_j, \ln r_j\}$ are the action-angle variables in the generalized sense, introduced in the beginning of Section 5. Of course they are convenient for solving the TC model because: i) they satisfy canonical Poisson brackets and ii) the TC Hamiltonian takes the simple form:

$$H_{TC} = \sum_{j=1}^n 2\zeta_j^2. \quad (95)$$

Therefore the equations of motion for $\{\zeta_j, \ln r_j^2\}$ take the form:

$$\frac{d\zeta_j}{dt} = 0, \quad \frac{d\ln r_j^2}{dt} = -2\zeta_j, \quad j = 1, \ldots, n. \quad (96)$$

The situation changes substantially after the complexification, see [4]. In fact the same formulae [39, 44] provide the solution also for the complex case. But now we have neither of the properties 1) or 2). The eigenvalues $\zeta_j$, as well as $r_j$ become complex:

$$\zeta_j = \kappa_j + i\eta_j, \quad \rho_j + i\phi_j = \ln r_j e^{i\eta_j}, \quad j = 1, \ldots, n, \quad (97)$$

where

$$e^{-n\eta_j} = A_n = \prod_{j=1}^n r_j^2 W^2(1, \ldots, n).$$

This substantially modifies the properties of the solutions.

For CTC one can derive the analogs of the relations [93]:

$$\lim_{t \to \pm \infty} (q_k(t) - v_k^\pm t) = \beta_k^\pm, \quad (98)$$

$$v_k^- = -2\kappa_k, \quad v_k^+ = -2\kappa_{n+1-k}; \quad (99)$$

which shows that now it is the set of real parts $\{\kappa_j\}$ of the eigenvalues $\zeta_j$ which determine the asymptotic velocities. Even if we assume\footnote{In principle we may have $\zeta_j = \zeta_k$ for $k \neq j$ which leads to degenerate solutions; we will not consider such cases below, see e.g. [4].} that $\zeta_j \neq \zeta_{j'}$ for $j \neq j'$ then we still may have $\kappa_j = \kappa_{j'}$; note that equal asymptotic velocities allow for the possibility of bound states. Skipping the details (see [1]) we just list the different types of asymptotic regimes for the CTC which are determined by the so-called sorting condition:

$$\kappa_1 \geq \kappa_2 \geq \ldots \geq \kappa_n. \quad (100)$$

This sorting condition differs from [1], for the real TC in that it allows equalities. Therefore the CTC allows several non-degenerate regimes:

A) Asymptotically free regime: $\kappa_j \neq \kappa_{j'}$ for $j \neq j$;

B) $n$-particle bound state for $\kappa_1 = \kappa_2 = \ldots = \kappa_n$;

C) A number of mixed regimes when we have two or more groups of equal $\kappa_j$'s.

Another difference with respect to the real TC case is that $A_k(t)$ are no more positive definite. For some choices of the $\zeta_j$ and $r_j$ they may vanish even for finite values of $t = t_0$ which means that $q_k(t)$ may develop singularity for $t \to t_0$.

Let us now analyze the effect of the involutions $C$ and $\tilde{C} \equiv C \circ *$ on the spectral data $\{\zeta_k, \ln r_k\}$ of $L$. It will allow us to describe the dynamical regimes of the RHF of CTC. Eq. (93) leads to:

$$\tilde{C}(q_k) = -q_{n+1-k}^*, \quad \tilde{C}(p_k) = -p_{n+1-k}^*, \quad (101)$$

and consequently:

$$\tilde{C}(b_k) = -b_{n+1-k}^*, \quad \tilde{C}(a_k) = a_{n-k}^*. \quad (102)$$

These constraints mean that the Lax matrix $L$ satisfies:

$$S_0 L(\tilde{C}(p_k), \tilde{C}(q_k)) S_0^{-1} = -L(p_k, q_k)^\dagger, \quad (103)$$

$$S_0 = \begin{pmatrix} 0 & 0 & \ldots & 0 \\ 0 & 0 & \ldots & -10 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & (-1)^{n-1} & \ldots & 0 \\ -(-1)^n & 0 & \ldots & 0 \end{pmatrix}. \quad (104)$$

This means that the eigenvalues and the matrix of eigenvectors of $L$ satisfy:

$$S_0 Z S_0^{-1} = -Z^*, \quad Z = \text{diag}(\zeta_1, \ldots, \zeta_n) \quad \text{or} \quad \tilde{C}(\zeta_k) = -\zeta_{n+1-k}^*. \quad (105)$$
Technically it is a bit more difficult to derive the action of $\tilde{C}(rk)$. Indeed, this must ensure that the functions $A_k$ satisfy
\begin{equation}
\tilde{C}(A_k) = A_k^{n-k},
\end{equation}
for all values of $t$. After some calculations we get that the relations
\begin{equation}
\rho_{n+1-k} + i\phi_{n+1-k} = -\rho_k + i\phi_k + \ln w_k,
\end{equation}
\begin{equation}
w_k = \frac{W(1, \ldots, k-1, k+1, \ldots, n)}{W(1,2,\ldots, n)}
\end{equation}
ensure that $B_n^{*} = B_k$ where
\begin{equation}
B_k(t) = A_k(t)e^{-\kappa_1(0)}.
\end{equation}

Let us illustrate this by first putting $n = 4$ and choosing
\begin{align*}
\zeta_1 &= -\zeta_4^{*} = \kappa_1 + i\eta_1, & \zeta_2 &= -\zeta_3^{*} = \kappa_1 - i\eta_1, \\
\rho_1 &= \rho_0 + i\phi_0, & \rho_3 &= -\rho_0 - i(\phi_0 + \alpha + \frac{\pi}{2}), \\
\rho_2 &= \rho_0 - i\phi_0, & \rho_4 &= -\rho_0 + i(\phi_0 + \alpha + \frac{\pi}{2}).
\end{align*}

With these notations we can write down the solution for the $sl(4)$-CTC in the form:
\begin{align}
q_1(t) &= \ln B_1(t), & q_2(t) &= \ln B_2(t) - B_1(t), \\
q_3(t) &= \ln B_3(t) - B_2(t) = -q_2(t), & q_4(t) &= -\ln B_4(t) = -q_1(t),
\end{align}
where
\begin{align}
B_1(t) &= \frac{1}{2^{2\kappa_1(1)}\sqrt{\kappa_1^2 + \eta_1^2}} [e^{-2\kappa_1 t + 2\rho_0} \cos(2\eta_1 t - 2\phi_0) \\
&- e^{2\kappa_1 t - 2\rho_0} \cos(2\eta_1 t - 2\phi_0 - 2\alpha)] \quad \text{(111)}, \\
B_2(t) &= \frac{-1}{2^{2\kappa_1^2 + \eta_1^2}} \left[ \eta_1^2 \cosh(4\eta_1 t - 4\phi_0) \\
&+ \kappa_1^2 \cos(4\eta_1 t - 4\phi_0 - 2\alpha) + \eta_1^2 \right], \\
B_3(t) &= B_1^{*}, & \alpha_1 &= \arg \zeta_1 = \arctan \frac{\eta_1}{\kappa_1}.
\end{align}

The choice of $\zeta_1 = \zeta_4^{*}$ in (108) combined with the involution $\zeta_1 = -\zeta_4^{*}$, $\zeta_2 = -\zeta_3^{*}$ ensures that $q_1(t)$ and $q_2(t)$ will have equal asymptotic velocities and will form a bound state. Indeed, from (111) and (111) we get:
\begin{align}
\lim_{t \to \pm \infty} \left( \frac{1}{2}(q_1(t) + q_2(t)) \mp 2\kappa_1 t \right) &= \frac{i\pi}{2} \mp 2\rho_0 \\
&- \frac{1}{2} \ln 2^{2\kappa_1^2 + \eta_1^2} + O(e^{-4\kappa_1|t|}) \quad \text{(112)},
\end{align}
which means that the center of mass of the particles $q_1(t)$ and $q_2(t)$ for $t \to \pm \infty$ undergoes non-compact asymptotically free motion with asymptotic velocities $\pm 2\kappa_1$. At the same time the relative asymptotic motion is compact:
\begin{align}
q_1(t) - q_2(t) &\to \frac{i\pi}{2} - 4\eta_1^2 + \ln \cos^2(\Phi^{\pm}(t)) \quad \text{(113)} \\
&+ O(e^{-2\kappa_1|t|}), \\
\Phi^{+}(t) &= 2\eta_1 t - 2\phi_0 - 2\alpha_1, & \Phi^{-}(t) &= 2\eta_1 t - 2\phi_0.
\end{align}

The energy of these RHF of $sl(4)$-CTC is given by:
\begin{equation}
H_{sl(4)} = 8(\kappa_1^2 - \eta_1^2). \quad \text{(114)}
\end{equation}

Due to the symmetry the ‘particles’ $q_3(t)$ and $q_4(t)$ also form a bound state; the corresponding formulae easily follow from (112) and (113) and $q_4(t) = -q_1^{*}(t)$ and $q_3(t) = -q_2^{*}(t)$.

This example demonstrates several peculiarities of the RHF dynamics. The first one is that configurations in which all $n$ particles form a bound state is impossible. Indeed, such bound state may take place if $\kappa_j = 0$ for all $j = 1, \ldots, n$. But it is easy to check that the sorting condition and the symmetry of the eigenvalues lead to degeneracy of the spectrum of $L$ for $\kappa_j = 0$.

The RHF dynamics allows either asymptotically free regimes or mixed regimes with special symmetry, namely we can have only even number of bound states which move with opposite asymptotic velocities.

The above considerations on the properties of the dynamical regimes are not specific for the Toda chain. Similar conclusions can be derived also for the RHF of the Calogero-Moser systems. Here we have richer variety of RHF’s due to the fact that the CMS Hamiltonian is invariant with respect to the whole Weyl group of $g$. More detailed investigation of the CMS dynamical regimes will be done elsewhere.

### 9 Discussion

1. The method goes also for non-integrable models, though we treated mainly integrable ones.

Other related aspects of our method concern more complicated objects such as dynamical classical $r$-matrices or quantum $R$-matrices due to their algebraic structures will also satisfy relations of the form (SS).

2. Our list of examples can be substantially extended with Ruijsenaars-Sneider models and their generalizations being among the obvious candidates.

3. The present approach can naturally be generalized also for infinite-dimensional integrable models such as the $1+1$-dimensional Toda field theories. This will allow one to construct new classes of real Hamiltonian forms of Toda field theories extending the results of [4].

4. The method can be used repeatedly: Since the complexified model can be viewed as real Hamiltonian system with $2n$ degrees of freedom, then we can start and complexify it getting a Hamiltonian system with $4n$ degrees of freedom producing a real form dynamics with $2n$ degrees of freedom.

If the initial system allows Lax representation that depends analytically on the dynamical parameters:
\begin{equation}
\frac{dL_0}{dt} = [L_0, M_0]. \quad \text{(115)}
\end{equation}
After the complexification we get complex-valued $L = L_0 + iL_1$ and $M = M_0 + iM_1$ which provide the Lax representation for the complexified system. But the
complexified system can be viewed as real Hamiltonian system with $2n$ degrees of freedom. It allows Lax representation with real-valued $L$ and $M$ of the form \[ L = \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix}, \quad M = \begin{pmatrix} \mathbf{A} & 0 \\ 0 & \mathbf{D} \end{pmatrix}, \]

5. Solutions of the initial system that depend analytically on the initial parameters ‘survive’ the complexification procedure. As we see from the CTC case discussed above, solutions that have been regular for all time after such procedure may develop singularities for finite $t$. Another substantial difference is in the asymptotic dynamical regimes. Projecting onto the RHF some of these singularities remain. Their asymptotic dynamical regimes need additional studies.

10 Acknowledgements

One of us (VSG) acknowledges financial support in part from Gruppo collegato di INFN at Salerno, Italy and project PRIN 2000 (contract 323/2002). The work of GM and GV was partially supported by PRIN SINTESI. One of us (VSG) thanks Professor F. Calogero for the hospitality at Rome University and the nice discussions concerning this paper. One of us (AK) is grateful to the Department of Physics and to for the hospitality of the University of Salerno and to INFN group at Salerno for their warm hospitality.
