On the Discrepancy Principle for Stochastic Gradient Descent

Tim Jahn∗ Bangti Jin†

May 1, 2020

Abstract

Stochastic gradient descent (SGD) is a promising numerical method for solving large-scale inverse problems. However, its theoretical properties remain largely underexplored in the lens of classical regularization theory. In this note, we study the classical discrepancy principle, one of the most popular a posteriori choice rules, as the stopping criterion for SGD, and prove the finite iteration termination property and the convergence of the iterate in probability as the noise level tends to zero. The theoretical results are complemented with extensive numerical experiments.

Key words: stochastic gradient descent, discrepancy principle, convergence

1 Introduction

In this work, we study the following finite-dimensional linear inverse problem:

\[ Ax = y^\dagger, \]

where \( x \in \mathbb{R}^m \) is the unknown signal of interest, \( y^\dagger \in \mathbb{R}^n \) is the exact data and \( A \in \mathbb{R}^{n \times m} \) is the system matrix. In practice, we have access only to a corrupted version \( y^\delta \) of the exact data \( y^\dagger = Ax^\dagger \) (with the reference solution \( x^\dagger \) being any exact solution)

\[ y^\delta = y^\dagger + \xi \]

where \( \xi \in \mathbb{R}^n \) denotes the noise, with a noise level \( \delta = \|\xi\| \). In the literature, a large number of numerical methods have been proposed for solving linear inverse problems accurately and efficiently (see, e.g., [3, 11, 7]).

When the size of problem (1.1) is massive, one attractive method is a simple stochastic gradient descent (SGD) [16, 2]. In its simplest form, it reads as follows: given an initial guess \( x_1^\delta = x_1 \in \mathbb{R}^m \), let

\[ x_{k+1}^\delta := x_k^\delta - \eta_k ((a_{i_k}, x_k^\delta) - y_{i_k}^\delta) a_{i_k}, \quad k = 1, 2, \ldots, \]

where \( \eta_k > 0 \) is a decreasing stepsize, \( a_i \) is the \( i \)-th row of the matrix \( A \) (as a column vector), \((\cdot, \cdot)\) denotes Euclidean inner product on \( \mathbb{R}^m \), and the row index \( i_k \) at the \( k \)th SGD iteration is chosen uniformly (with replacement) from the set \( \{1, \ldots, n\} \). Distinctly, the method operates only on one data point \((a_{i_k}, y_{i_k})\) each time, and thus it is directly scalable to the problem size \( n \). This feature makes it especially attractive in the context of massive data. In fact, SGD and its variants (e.g., minibatch and accelerated) have been established as the workhorse behind many challenging training tasks in deep learning [1, 2], and they are also popular for image reconstruction in computed tomography [3, 15].

Despite the apparent simplicity of the method, the mathematical theory in the lens of classical regularization theory is far from complete. In the work [8], the regularizing property of SGD was proved for a polynomially decaying stepsize schedule, when the stopping index \( k \) is determined a priori in relation with the noise level \( \delta \). Further, a convergence rate in the mean squared norm between the iterate \( x_k^\delta \) and the exact solution \( x^\dagger \) was derived, under suitable source type condition on the ground truth \( x^\dagger \). These results were recently extended to mildly nonlinear inverse problems, further assisted with suitable nonlinearity conditions of the forward map [9].

∗Institute for Mathematics, Goethe-University Frankfurt, Germany (jahn@math.uni-frankfurt.de)
†Department of Computer Science, University College London, Gower Street, London WC1E 6BT, UK (b.jin@ucl.ac.uk)
However, in these works, the convergence rate can only be achieved under a knowledge of the smoothness parameter of \( x^\dagger \), which is usually not directly accessible in practice. Therefore, it is of enormous practical importance and theoretical interest to develop a posteriori stopping rules that do not require such a knowledge.

For deterministic iterative methods [11], e.g., Landweber method and Gauss-Newton method, one popular a posteriori stopping rule is the discrepancy principle, due to Morozov [14]. Specifically, with \( x_k^\dagger \) being the \( k \)th iterate constructed by an iterative regularization method, the principle determines the stopping index \( k(\delta) \) by

\[
    k(\delta) := \min\{ k \in \mathbb{N} : \| Ax_k^\dagger - y^\delta \| \leq \tau \delta \}, 
\]

(1.3)

where the constant \( \tau > 1 \) is fixed. The use of the discrepancy principle to many deterministic iterative methods is well understood (see the monograph [11] and the references therein), but in the context of stochastic iterative methods, it has not been explored so far, to the best of our knowledge. The goal of this work is to study the basic property of the discrepancy principle for SGD. It is worth noting that a direct computation of the residual \( \| Ax_k^\dagger - y^\delta \| \) at every SGD iteration is demanding. However, one may compute it not at every SGD iteration but only with a given frequency (e.g., per epoch, see Section 5), as done by the popular stochastic variance reduced gradient [10], for which residual evaluation is part of gradient computation. Also there are efficient methods to determine \( \| Ax_k^\dagger - y^\delta \| \) using randomized SVD [12], by exploiting the intrinsic low-rank nature for many practical inverse problems.

Now we specify the algorithmic parameters for SGD, and state the main results of the work. Throughout, we make the following assumption on the stepsizes and the regularity condition on the ground truth solution \( x^\dagger \), i.e., the minimum-norm solution defined by

\[
    x^\dagger = \arg \min_{x : Ax = y^\dagger} \| x \|. 
\]

(1.4)

The stepsize schedule in (i) is commonly known as the polynomially decaying stepsize schedule, and (ii) is the classical power type source condition, where \( B = n^{-1}(A^TA) \), imposing a type of smoothness on the solution \( x^\dagger \) (relative to the system matrix \( A \) and the initial guess \( x_1 \)). In the analysis and computation below, \( x_1 \) is fixed at 0.

**Assumption 1.1. The following conditions hold.**

(i) The stepsizes \( \eta_j \) satisfy \( \eta_j = c_0j^{-\alpha} \), with \( \alpha \in (0, 1) \) and \( c_0 \leq (\max_{j=1,\ldots,m} \| a_j \|^2)^{-1} \).

(ii) There is a \( p > 0 \) and a \( w \in \mathbb{R}^m \) such that \( x^\dagger - x_1 = B^p w \).

The first theorem gives a finite-iteration termination property of the discrepancy principle, where \( \mathbb{P} \) is with respect to the filtration generated by the random index \( (i_k)_{k=1}^\infty \). It can also be viewed as a partial result on the optimality. It implies in particular that for \( p < \frac{1}{2} \), the data propagation error is of optimal order. The proof relies crucially on the observation that the variance component of the mean squared residual contributes only marginally for sufficiently large \( k \).

**Theorem 1.1.** Let Assumption 1.1 be fulfilled, and \( k(\delta) \) be determined by the discrepancy principle (1.3). Then for all \( 0 < r < 1 \) and \( \tau > \tau^* > 1 \), with \( c = \left( \frac{c_0}{\sqrt{m}p} \right)^{\frac{2}{r^2 + \alpha^2}} (\min(2r, \tau^*/\tau)) + 2 \), there holds

\[
    \mathbb{P} \left( k(\delta) \leq c \delta^{- \frac{2}{r^2 + \alpha^2}} (\min(2r, \tau^*/\tau)) + 2 \right) \rightarrow 1 \quad \text{as} \quad \delta \rightarrow 0^+, 
\]

with the constant \( c_p \) by

\[
    (c_0 \pi (2^{1-r} + 1))^{p + \frac{1}{2}} \| w \|. 
\]

The second contribution of this work is on the convergence in probability of the SGD iterate \( x_{k(\delta)}^\dagger \) with the stopping index \( k(\delta) \) determined by (1.3). This result has one drawback. In the proof, we have to assume that the stopping index \( k(\delta) \) is independent of the iterates \( x_{k(\delta)}^\dagger \). In practice, this can be achieved by running SGD twice with the same data \((y^\delta, \delta)\): the first round is for the determination of \( k(\delta) \), then the second (independent) round is stopped using \( k(\delta) \). This increases the computational expense by a factor of 2. However, the numerical results in Section 5 show that one can use the iterate from the first run without compromising the accuracy.

**Theorem 1.2.** Let Assumption 1.1 be fulfilled, and \( k(\delta) \) be determined by the discrepancy principle (1.3). Then for all \( \varepsilon > 0 \) there holds

\[
    \mathbb{P} \left( \| x_{k(\delta)}^\dagger - x^\dagger \| \geq \varepsilon \right) \rightarrow 0 \quad \text{as} \quad \delta \rightarrow 0^+, 
\]

where \( (x_{k(\delta)}^\dagger)_{k \in \mathbb{N}} \) are SGD iterates independent of \( k(\delta) \), with the same data \((y^\delta, \delta)\).
In sum, Theorems 1.1 and 1.2 confirm that the discrepancy principle is a valid *a posteriori* stopping rule for SGD. However, they do not give a rate of convergence, which remains an open problem. Numerically, we observe that the convergence rate obtained by the discrepancy principle is nearly order-optimal for low-regularity solutions, as the *a priori* rule in the regime in [8], and the performance is competitive with the standard Landweber method. Thus, the method is especially attractive for finding a low-accuracy solution. However, for very smooth solutions (i.e., large $p$), it manifested as a highly undesirable saturation phenomenon, due to the presence of the significant variance component (when compared with the approximation error), under the setting of Assumption 1.1. The rest of the paper is organized as follows. In Sections 2 and 3, we prove Theorems 1.1 and 1.2, respectively. Several auxiliary results needed for the proof of Theorem 1.1 are given in Section 4. Finally, several numerical experiments are presented in Section 5 to complement the theoretical analysis. We conclude with some useful notation. We denote the SGD iterate for exact data $y$ by $x_k$, and that for noisy data $y^\delta$ by $x_k^\delta$. The expectation $E[\cdot]$ is with respect to the filtration $\mathcal{F}_k$ generated by the random indices $\{i_1, \ldots, i_k, \ldots\}$.

2 The proof of Theorem 1.1

In this section, we give the proof of Theorem 1.1. First, we give several preliminary facts. By the construction in (1.2), since $x_k^\delta$ is measurable with respect to $\mathcal{F}_{k-1}$, 

$$E[x_{k+1}^\delta | \mathcal{F}_{k-1}] = x_k^\delta - \eta_k n^{-1} \sum_{i=1}^n ((a_i, x_k^\delta) - y_i^\delta) a_i = x_k^\delta - \eta_k n^{-1} (A^t A x_k^\delta - A^t y^\delta).$$

Thus, by the law of total expectation, the sequence $(E[x_k^\delta])_{k \in \mathbb{N}}$ satisfies the following recursion:

$$E[x_{k+1}^\delta] = E[x_k^\delta] - \eta_k (\bar{A}^t \bar{A} E[x_k^\delta] - \bar{A}^t \bar{y}^\delta)$$

(2.1)

with $\bar{A} = n^{-\frac{1}{2}} A$ and $\bar{y}^\delta = n^{-\frac{1}{2}} y^\delta$. This is exactly the classical Landweber method (1.3) (but with diminishing stepsizes) applied to the rescaled linear system $\bar{A} \bar{x} = \bar{y}^\delta$. For the Landweber method, the discrepancy principle (1.3), e.g., regularizing property and optimal convergence rates, has been thoroughly studied for both linear and nonlinear inverse problems (see, e.g., [3, Chapter 6] and [11]). The key insight for the analysis below is the following empirical observation: for a suitably large $k$, typically the variance component $E[\| A(x_k^\delta - E[x_k^\delta])\|^2] \ll \delta^2$, as confirmed by the numerical experiments in Section 5.2. This fact allows us to transfer the results for the Landweber method to SGD.

The proof of Theorem 1.1 employs two preliminary results, whose lengthy proofs are deferred to Section 3 below. The first result gives an upper bound of the following stopping index $k^*(\delta)$, for any $\tau^* > 1$, defined by

$$k^*(\delta) := \min\{k \in \mathbb{N} : \| \bar{A} E[x_k^\delta] - y^\delta \| \leq \tau^* \delta \}. $$

(2.2)

Clearly, $k^*(\delta)$ is the stopping index by the classical discrepancy principle, when applied to the sequence $(E[x_k^\delta])_{k \in \mathbb{N}}$, which is exactly the Landweber method, in view of the relation (2.1).

**Proposition 2.1.** Let Assumption 1.1 be fulfilled. Then for $k^*(\delta)$ defined in (2.2), there holds

$$k^*(\delta) \leq \left( \frac{\tau^* - 1}{\sqrt{\eta_0}} \right) \left( \frac{\eta_0}{\eta_0 + \eta_0(1 - \alpha)} \right)^{p+\frac{1}{2}} \| w \| + 2,$$

(2.3)

with $c_p = \left( \frac{\eta_0}{\eta_0 + \eta_0(1 - \alpha)} \right)^{p+\frac{1}{2}} \| w \|$.

The second result gives an upper bound on the variance $E[\| A(x_{k^*(\delta)}^\delta - \bar{E}[x_{k^*(\delta)}^\delta])\|^2]$ of the residual $E[\| A x_k^\delta - y^\delta \|^2]$. It indicates that the variance $E[\| A(x_{k^*(\delta)}^\delta - \bar{E}[x_{k^*(\delta)}^\delta])\|^2]$ contributes only marginally to the mean squared residual $E[\| A x_k^\delta - y^\delta \|^2]$, and consequently the squared residual $\| A x_k^\delta - y^\delta \|^2$ of individual realizations of SGD may be used instead for determining an appropriate stopping index.
Proposition 2.2. Under Assumption 1.1 with \( \kappa(\delta) \geq \delta^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \) and \( 0 < r < 1 \), there holds
\[
E[\|A(x^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}])\|^2] = o(\delta^2), \quad \text{as } \delta \to 0^+.
\]

Now we can present the proof of Theorem 1.1.

Proof. Set \( 1 < \tau^* < \tau \) and \( \tilde{k}(\delta) = \lceil c\delta^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \rceil + 2 \) (where \( \lceil \cdot \rceil \) denotes taking the integral part of a real number), with \( c = (\frac{\tau^* - 1}{\sqrt{\log p}})^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \). By the definition of \( k(\delta) \) in (1.3), the event \( \mathcal{E} = \{ k(\delta) \leq \tilde{k}(\delta) \} \) is given by
\[
\mathcal{E} = \{ \exists i \in \{1, \ldots, \tilde{k}(\delta)\} \text{ such that } \|Ax^\delta_i - y^\delta\| \leq \tau \delta \}.
\]
Thus, \( \mathcal{E} \supset \{ \|Ax^\delta_{k(\delta)} - y^\delta\| \leq \tau \delta \} \). Consequently,
\[
\mathbb{P}(k(\delta) \leq \tilde{k}(\delta)) \geq \mathbb{P}(\|Ax^\delta_{k(\delta)} - y^\delta\| \leq \tau \delta) \\
\geq \mathbb{P}(\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\| \leq (\tau - \tau^*)\delta, \|AE[x^\delta_{k(\delta)}] - y^\delta\| \leq \tau^*\delta).
\]
By the choice of \( \tilde{k}(\delta) \), Proposition 2.1 implies
\[
\|AE[x^\delta_{k(\delta)}] - y^\delta\| \leq \tau^*\delta.
\]
Consequently,
\[
\mathbb{P}(k(\delta) \leq \tilde{k}(\delta)) \geq \mathbb{P}(\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\| \leq (\tau - \tau^*)\delta) \\
= 1 - \mathbb{P}(\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\| > (\tau - \tau^*)\delta).
\]
Meanwhile, by Chebyshev’s inequality [4, p. 233], we have
\[
\mathbb{P}(\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\| > (\tau - \tau^*)\delta) \leq \frac{E\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\|^2}{(\tau - \tau^*)^2\delta^2}.
\]
Therefore,
\[
\mathbb{P}(k(\delta) \leq \tilde{k}(\delta)) \geq 1 - \frac{E\|Ax^\delta_{k(\delta)} - E[x^\delta_{k(\delta)}]\|^2}{(\tau - \tau^*)^2\delta^2},
\]
which together with Proposition 2.2 directly implies
\[
\mathbb{P}(k(\delta) \leq \tilde{k}(\delta)) \to 1 \quad \text{as } \delta \to 0^+.
\]
This completes the proof of the theorem. \( \square \)

Remark 2.1. The condition \( r < 1 \) is related to an apparent saturation phenomenon with SGD: for any \( p > \frac{1}{2} \), the SGD iterate \( x^\delta_k \) with a priori stopping can only achieve a convergence rate comparable with that for \( p = \frac{1}{2} \), at least for the current analysis [8]. It remains unclear whether this is an intrinsic drawback of SGD or due to limitations of the proof technique.

Remark 2.2. In practice, we prefer computing the residual with a frequency \( \omega n \in \mathbb{N} \):
\[
k_\omega(\delta) := \min\{\omega n : k \in \mathbb{N}, \|Ax^\delta_{\omega n k} - y^\delta\| \leq \tau \delta\}.
\]
Since one of the numbers \( \lceil c\delta^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \rceil + 2, \ldots, \lceil c\delta^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \rceil + \omega n + 1 \) is of the form \( \omega n k \), with \( k \in \mathbb{N} \), there holds
\[
\mathbb{P}\left(k_\omega(\delta) \leq \lceil c\delta^{-\frac{1}{(r-\alpha)(\min(2p,r)+1)}} \rceil + \omega n + 1 \right) \to 1 \quad \text{as } \delta \to 0^+.
\]
That is, the upper bound on the stopping index remains largely valid for the variant of the discrepancy principle [1.3] evaluated with a frequency.
3 The proof of Theorem 1.2

In this section, we prove Theorem 1.2. It employs the following proposition, which states that potential early stopping actually does not cause any problem.

**Proposition 3.1.** For all \( \varepsilon > 0 \), there is a sequence \( (k_\delta)_{\delta} \) with \( k_\delta \rightarrow \infty \) for \( \delta \rightarrow 0^+ \), such that

\[
\|x^\delta_{k(\delta)} - x^\dagger\| \chi\{k(\delta) \leq k_\delta\} \leq \varepsilon
\]

for \( \delta > 0 \) small enough.

**Proof.** It suffices to show that for all \( K \in \mathbb{N} \)

\[
\|x_{k(\delta)} - x^\dagger\| \chi\{k(\delta) \leq K\} \rightarrow 0 \quad \text{as} \quad \delta \rightarrow 0^+.
\]

(3.1)

In order to show this, we need the following two estimates for the iterated noise:

\[
\|A(x^\delta_k - x_k) - (y^\delta - y^\dagger)\| \leq \delta \prod_{j=1}^{k-1} (1 + \eta_j \|A\|^2),
\]

(3.2)

\[
\|x^\delta_k - x_k\| \leq \delta \|A\| \sum_{j=1}^{k-1} \eta_j \prod_{i=1}^{j-1} (1 + \eta_i \|A\|^2).
\]

(3.3)

with the conventions \( \sum_{j=1}^{0} = 0 \) and \( \prod_{j=1}^{0} = 1 \). We prove the estimates (3.2) and (3.3) by mathematical induction. Note that \( a_i = A^i e_i \). For the estimate (3.2), by the triangle inequality and the defining relation (1.2) of SGD iteration,

\[
\|A(x^\delta_{k+1} - x_{k+1}) - (y^\delta - y^\dagger)\|
\leq \|A(x^\delta_k - x_k) - (y^\delta - y^\dagger)\| + \eta_k \|A(x^\delta_k - x_k) - (y^\delta - y^\dagger), e_{ik}\| AA^i e_{ik}\|
\leq \|A(x^\delta_k - x_k) - (y^\delta - y^\dagger)\| (1 + \eta_k \|A\|^2),
\]

and since \( x_1 = x^\delta_1 \), \( \|A(x^\delta_1 - x_1) - (y^\delta - y^\dagger)\| = \|y^\delta - y^\dagger\| \leq \delta \). For the estimate (3.3), we have \( \|x^\dagger_1 - x_1\| = 0 \) and

\[
\|x^\delta_{k+1} - x_{k+1}\| \leq \|x^\delta_k - x_k\| + \eta_k \|A\| \|A(x^\delta_k - x_k) - (y^\delta - y^\dagger)\|,
\]

so the claim follows using the estimate (3.2). Now, for each fixed \( K \), since there are only finitely many different realisations of the first \( K \) SGD-iterates, there is a (deterministic) \( \eta > 0 \), which depends on \( K \), such that

\[
\min_{k=1,\ldots,K} \left( \|Ax_k - y^\dagger\| - \eta \right) \chi\{\|Ax_k - y^\dagger\| > 0\} \geq 0,
\]

(3.4)

where without loss of generality, we have assumed \( y^\dagger \neq 0 \). Therefore, using estimates (3.2) and (3.4),

\[
\|Ax^\delta_k - y^\delta\|_\infty \chi\{\|Ax_k - y^\dagger\| > 0\}
\geq \|Ax_k - y^\dagger\|_\infty \chi\{\|Ax_k - y^\dagger\| > 0\} - \|A(x_k - x^\delta_k) - (y^\dagger - y^\delta)\|_\infty \chi\{\|Ax_k - y^\dagger\| > 0\}
\geq \left( \eta - \delta \prod_{j=1}^{k-1} (1 + \eta_j \|A\|^2) \right) \chi\{\|Ax_k - y^\dagger\| > 0\} > \tau \delta \chi\{\|Ax_k - y^\dagger\| > 0\}
\]

for any \( \delta < \frac{\eta}{\tau \prod_{j=1}^{k-1} (1 + \eta_j \|A\|^2)} \). Then by the definition of the discrepancy principle in (1.3), this implies

\[
\{k(\delta) \leq K\} \subset \{\|Ax_k(\delta) - y^\dagger\| = 0\}
\]
for \( \delta > 0 \) small enough. Meanwhile, since by construction \( x_{k(\delta)} \in R(A') = N(A)^\perp, \|Ax_{k(\delta)} - y^\dagger\| = 0 \) implies \( x_{k(\delta)} = x^\dagger \), the minimum norm solution. The proof of (3.1) is concluded by

\[
\|x^\delta_{k(\delta)} - x^\dagger\| \chi\{k(\delta) \leq K\} = \|x^\delta_{k(\delta)} - x_{k(\delta)}\| \chi\{k(\delta) \leq K\} \\
\leq \delta \|A\| \sum_{j=1}^{K-1} \eta_j \prod_{i=1}^{j-1} (1 + \eta_i \|A\|^2) \to 0
\]

for \( \delta \to 0^+ \), where we have used estimate (3.3). This completes the proof of the proposition.

Now we can state the proof of Theorem 1.2

**Proof of Theorem 1.2** Fix \( \varepsilon > 0 \). Proposition 3.1 and Theorem 1.1 guarantee the existence of two sequences \((k^-_\delta)\), \((k^+_\delta)\), with \( k^-_\delta \leq k^+_\delta \leq c\delta^{-\frac{1}{2}+\min\{2p,\gamma\}+\gamma} \), \( k^-_\delta \to \infty \) for \( \delta \to 0^+ \) and

\[
\|x^\delta_{k(\delta)} - x^\dagger\| \chi\{k(\delta) \leq k^-_\delta\} \leq \varepsilon \quad \text{for } \delta \text{ small enough}
\]

and

\[
\mathbb{P}(k(\delta) \leq k^+_\delta) \to 1 \quad \text{for } \delta \to 0^+.
\]

Consequently, for \( \delta > 0 \) small enough, there holds

\[
\mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon) \\
= \mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k(\delta) \leq k^-_\delta) + \mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k(\delta) > k^-_\delta) \\
= \mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k(\delta) < k^-_\delta) + \mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k(\delta) > k^+_\delta) \\
\leq \mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k^-_\delta < k(\delta) \leq k^+_\delta) + \mathbb{P}(k(\delta) > k^+_\delta).
\]

In view of Theorem 1.1 it remains to show that

\[
\mathbb{P}(\|x^\delta_{k(\delta)} - x^\dagger\| > \varepsilon, k^-_\delta < k(\delta) \leq k^+_\delta) \to 0 \quad \text{for } \delta \to 0^+.
\]

To this end, let \( \Omega_\delta := \{k^-_\delta \leq k(\delta) \leq k^+_\delta\} \) and we split the error into three parts in a customary way: approximation error, data propagation error and stochastic error. Specifically, by the triangle inequality, there are constants \( c_1 \) and \( c_2 \) such that

\[
\|x^\delta_{k(\delta)} - x^\dagger\| \chi_\Omega_\delta = \sum_{k=k^-_\delta}^{k^+_\delta} \|x^\delta_k - x^\dagger\| \chi\{k(\delta) = k\} \\
\leq \sum_{k=k^-_\delta}^{k^+_\delta} \left( \|\mathbb{E}[x_k] - x^\dagger\| + \|\mathbb{E}[x_k] - \mathbb{E}[x^\delta_k]\| + \|x^\delta_k - \mathbb{E}[x^\delta_k]\| \right) \chi\{k(\delta) = k\} \\
\leq \sum_{k=k^-_\delta}^{k^+_\delta} \left( c_1 (k-1)^{-\frac{1}{2}+\min\{2p,\gamma\}+\gamma} + \|x^\delta_k - \mathbb{E}[x^\delta_k]\| \right) \chi\{k(\delta) = k\} \\
\leq c_1 (k^-_\delta - 1)^{-\frac{1}{2}+\min\{2p,\gamma\}+\gamma} + c_2 \delta (k^-_\delta - 1)^{-\frac{1}{2}+\min\{2p,\gamma\}+\gamma} + \sum_{k=k^-_\delta}^{k^+_\delta} \|x^\delta_k - \mathbb{E}[x^\delta_k]\| \chi\{k(\delta) = k\},
\]

where we have used [3] Theorem 3.2 and Lemma 4.1 below in the third line. The first two terms clearly tend to 0 for \( \delta \to 0^+ \) (since \( k^-_\delta \to \infty \), and \( \delta(k^-_\delta)^{-\frac{1}{2}+\min\{2p,\gamma\}+\gamma} \to 0 \), in view of Theorem 1.1. By Markov’s inequality [3] p. 242 and
the independence assumption between \(k(\delta)\) and \(x^\delta_{k(\delta)}\),
\[
P\left(\sum_{k=k_\delta^+}^{k_\delta^-} \|x^\delta_k - E[x^\delta_k]\| \chi(k(\delta) = k) > \epsilon'\right) \leq \frac{\sum_{k=k_\delta^+}^{k_\delta^-} E[\|x_k - E[x_k]\| \chi(k(\delta) = k)]}{\epsilon'} = \frac{\sum_{k=k_\delta^+}^{k_\delta^-} E[\|x_k - E[x_k]\|] P(k(\delta) = k)}{\epsilon'}.
\]

Now Jensen’s inequality and Proposition 4.1 below (with \(s = 0\), \(\gamma < \min(\alpha, 1 - \alpha)\) and \(\beta < 1 - \alpha\) gives
\[
P\left(\sum_{k=k_\delta^+}^{k_\delta^-} \|x^\delta_k - E[x^\delta_k]\| \chi(k(\delta) = k) > \epsilon'\right) \leq \frac{\sum_{k=k_\delta^+}^{k_\delta^-} \sqrt{E[\|x_k - E[x_k]\|^2]} P(k(\delta) = k)}{\epsilon'} \leq \frac{\sqrt{c(k^-_\delta)^{-\beta} + \delta^2(\delta^-_\delta)^{-\gamma}}}{} \leq \frac{\sqrt{c(k^-_\delta)^{-\beta} + \delta(\delta^-_\delta)^{-\gamma}} \cdot (\Omega_\delta)}{\epsilon'} \to 0
\]
as \(\delta \to 0^+\). Thus it follows that
\[
P\left(\|x_k(\delta) - x^\dagger\| > \epsilon, k^-_\delta < k(\delta) \leq k^+_\delta\right) \to 0
\]
as \(\delta \to 0^+\). This completes the proof of the theorem.

**Remark 3.1.** Clearly, with \(k_\omega(\delta)\) given as in Remark 2.2, there holds \(P(\|x_{k_\omega}(\delta) - x^\dagger\| \geq \epsilon) \to 0\) for \(\delta \to 0^+\). That is, the convergence remains valid for the variant of the discrepancy principle (1.3) evaluated with a frequency.

### 4 The proofs of Propositions 2.1 and 2.2

In this part, we prove Propositions 2.1 and 2.2 which are used in the proof of the Theorems 1.1 and 1.2. We shall use the following result from [8, Theorem 3.1] frequently. Note that \(\|B^\frac{1}{2}(x_k - x^\dagger)\| = \|Ax_k - y^\dagger\|/\sqrt{n}\).

**Lemma 4.1.** Let Assumption 1.1 be fulfilled, then for \(s \in \{0, 1/2\}\) and \(c_{p,s} := \left(\frac{E^s}{c_{0\epsilon}(2^{s-1}-1)}\right)^{p+s} \|u\|\), there holds
\[
\|B^s(x_{k+1} - x^\dagger)\| \leq c_{p,s} k^{-(p+s)(1-\alpha)}.
\]

#### 4.1 The proof of Proposition 2.1

**Proof.** We may assume \(k^* > 2\). By the definition of \(k^*(\delta)\) and the triangle inequality
\[
\tau^* \delta \leq \|AE[x^\delta_{k^*-1} - y^\delta]\| \leq \|AE[x_{k^*-1} - y^\dagger]\| + \|AE[x^\delta_{k^*-1} - x_{k^*-1}] + (y^\dagger - y^\delta)\|.
\]
By Lemma 4.1 the term \(\|AE[x_{k^*-1} - y^\dagger]\|\) is bounded by
\[
\|AE[x_{k^*-1} - y^\dagger]\| \leq c_p(k^* - 2)^{-(p+\frac{1}{2})(1-\alpha)} \quad \text{with} \quad c_p = \sqrt{n}c_{p,1/2}.
\]
Next we claim
\[
\|AE[x^\delta_{k^*-1} - x_{k^*-1}] + (y^\dagger - y^\delta)\| \leq \delta.
\]
Combining (4.1) with (4.2) immediately implies the desired assertion. It remains to show the claim (4.2). To this end, we employ the filter of the Landweber method. The relation (2.1) implies that $E[x_{k}^\delta]$ satisfies the following recursion

$$AE[x_{k+1}^\delta] - y^\delta = \left(I - \frac{n}{n} AA^t\right) \left(AE[x_k^\delta] - y^\delta\right).$$

Using this yields

$$AE[x_k^\delta] - y^\delta = \prod_{j=1}^{k-1} \left(I - \frac{n}{n} AA^t\right) \left(Ax_1 - y^\delta\right),$$

and consequently, by the choice of $c_0$,

$$||AE[x_{k^*+1}^\delta - x_{k^*+1}] + (y^\delta - y^\delta)|| = \left|\prod_{j=1}^{k^*} \left(I - \frac{n}{n} AA^t\right) \left(y^\delta - y^\delta\right)\right| \leq \delta. \quad (4.3)$$

This completes the proof of the proposition.

\[
\begin{proof}
\end{proof}
\]

4.2 Proof of Proposition 2.2

The proof of Proposition 2.2 employs several technical estimates [8].

Lemma 4.2. For any $j < k$, and any symmetric and positive semidefinite operator $S$ and stepsizes $\eta_j \in (0, ||S||^{-1})$ and $p \geq 0$, there holds

$$\left|\prod_{i=j}^{k} (I - \eta_i S)^p\right| \leq \frac{\eta^p}{e^p(\sum_{i=j}^{k} \eta_i)^p}. \quad (4.5)$$

Next we recall two useful estimates taken from [8].

Lemma 4.3. For $\eta_j = \eta_0 j^{-\alpha}$ with $\alpha \in (0, 1)$, $\beta \in [0, 1]$ and $p \geq 0$, there hold

$$\sum_{j=1}^{\lfloor \frac{k}{2} \rfloor} \frac{\eta_j^2}{(\sum_{i=j}^{\lfloor \frac{k}{2} \rfloor} \eta_i)^r} \leq c_{\alpha, \beta, r} k^{-r(1-\alpha) + \max(0,1 - 2\alpha - \beta)},$$

$$\sum_{j=\lfloor \frac{k}{2} \rfloor + 1}^{k-1} \frac{\eta_j^2}{(\sum_{i=j}^{k} \eta_i)^r} \leq c'_{\alpha, \beta, r} k^{-(2-r)\alpha + \max(0,1 - r)},$$

where we slightly abuse the notation $k^{-\max(0,0)}$ for $\ln k$, and $c_{\alpha, \beta, r}$ and $c'_{\alpha, \beta, r}$ are given by

$$c_{\alpha, \beta, r} = \begin{cases} 2 r \eta_0^{2-r} & \frac{2\alpha + \beta}{2\alpha + \beta - 1}, \quad 2 \alpha + \beta > 1, \\ 2, & 2 \alpha + \beta = 1, \quad 2, & 2 \alpha + \beta < 1, \end{cases} \quad \text{and} \quad c'_{\alpha, \beta, r} = \begin{cases} 2^{2\alpha + \beta} \eta_0^{2-r} & \frac{r}{r-1}, \quad r > 1, \\ \frac{2r-1}{1-r}, & r = 1, \quad \frac{2r-1}{1-r}, & r < 1. \end{cases}$$

The next result gives an important recursion between the variance estimate.

Lemma 4.4. Let Assumption 1.1 be fulfilled. Then for the SGD iterate $x_k^\delta$, with $\delta_j^\phi = ||B^\delta x_j^\phi||$, there holds

$$E[\|B^\delta (x_{k+1}^\delta - E[x_{k+1}^\delta])\|^2] \leq \sum_{j=1}^{k} \eta_j^2 (\delta_j^\phi)^2 \left(c_s E[\|B^\delta (x_j^\phi - E[x_j^\phi])\|^2] + 2c_p j^{-2(1-\alpha)(p+\frac{1}{2}) + 2\delta^2}\right),$$

with $s \in \{0, \frac{1}{2}\}$ and $c_s, c_p$ given below.
Proposition 4.1. \(c\) which completes the proof of the lemma with \(j\).

Proof. By [S Theorem 3.3] and the bias variance decomposition, the left hand side (LHS) is bounded by

\[
\text{LHS} \leq \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 \mathbb{E}[\|Ax_j^\delta - y^\delta\|^2]
\]

\[
= \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 \left( \mathbb{E}[\|A(x_j^\delta - \mathbb{E}[x_j^\delta])\|^2] + \|AE[x_j^\delta] - y^\delta\|^2 \right).
\]

Now by the triangle inequality and (4.3),

\[
\text{LHS} \leq \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 \left( \mathbb{E}[\|A(x_j^\delta - \mathbb{E}[x_j^\delta])\|^2] + (\|AE[x_j] - y^\delta\| + \|A(\mathbb{E}[x_j^\delta] - \mathbb{E}[x_j]) - (y^\delta - y^\delta)\|)^2 \right)
\]

Since \(\|AE[x_1] - y^\delta\| = \|y^\delta\|\), and

\[
\|AE[x_j] - y^\delta\| \leq \sqrt{n\alpha_p} \frac{1}{2} (j - 1)^{-\left(p + \frac{1}{2}\right)(1 - \alpha)} \leq \sqrt{n\alpha_p} \frac{1}{2} 2^{(p + \frac{1}{2})(1 - \alpha)} - \left(p + \frac{1}{2}\right)(1 - \alpha)
\]

for \(j \geq 2\) by Lemma 4.1. Thus, with \(c_p := \left(\max\{\|y^\delta\|, \sqrt{n\alpha_p} \frac{1}{2} 2^{(p + \frac{1}{2})(1 - \alpha)}\}\right)^2\),

\[
\text{LHS} \leq \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 \left( n^{2s}\|A\|_4^{-1} \max\{\|y^\delta\|, \sqrt{n\alpha_p} \frac{1}{2} 2^{(p + \frac{1}{2})(1 - \alpha)}\} + 2c_p \right. + 2\delta^2
\]

which completes the proof of the lemma with \(c_s = n^{2s}\|A\|_4^{4(\frac{1}{2} - s)}\).

The next result gives a sharp estimate on \(\mathbb{E}[\|B^*(x_k^\delta - \mathbb{E}[x_k^\delta])\|^2]\).

Proposition 4.1. Let Assumption I.1 be fulfilled. Then for the SGD iterate \(x_k^\delta\), the mean squared error \(\mathbb{E}[\|B^*(x_k^\delta - \mathbb{E}[x_k^\delta])\|^2]\) with \(s \in \{0, \frac{1}{2}\}\) satisfies

\[
\mathbb{E}[\|B^*(x_k^\delta - \mathbb{E}[x_k^\delta])\|^2] \leq c(\alpha, p, n, s, \beta, \gamma)(k^{-\beta} + \delta^2k^{-\gamma})
\]

for \(\beta < \min((1 + 2s)(1 - \alpha), (1 + 2p)(1 - \alpha) + \beta)\) and \(\gamma < \min(\alpha, 1 - \alpha)\).

Proof. Lemma 4.4 implies that the weighted mean squares error \(d_j^s = \mathbb{E}[\|B^*(x_k^\delta - x_1^\delta)\|^2]\) satisfies the following recursion

\[
d_{k+1}^s \leq \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 \left( c_s d_j^s + 2c_p j^{-2(1 - \alpha)}(p + \frac{1}{2}) +2\delta^2 \right)
\]

(4.4)

Now we prove the desired assertion by mathematical induction (with \(\beta = (2p + 1)(1 - \alpha)\)):

\[
d_k^s \leq c(k^{-\beta} + \delta^2k^{-\gamma}),
\]

where the constant \(c \geq 1\) is to be determined. This assertion holds trivially for all finite \(k\), up to \(k^\ast\), provided that \(c\) is sufficiently large. Now suppose the assertion holds for \(k \geq k^\ast\), and we prove the assertion for \(k + 1\). Indeed, it follows from the recursion (4.4), the induction hypothesis and since \(\beta < 2(1 - \alpha)(p + \frac{1}{2})\), that

\[
d_{k+1}^s \leq \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 (c_s j^{-\beta} + j^{-\gamma} \delta^2) + 2c_p \eta_j^2(\phi_j^*)^2 (p + \frac{1}{2}) + 2\delta^2
\]

\[
\leq c_s \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 j^{-\beta} + (c_s c + 2)\delta^2 \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 + 2c_p \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 j^{-2(1 - \alpha)(p + \frac{1}{2})}
\]

\[
\leq (c_s c + 2c_p) \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2 j^{-\beta} + (c_s c + 2)\delta^2 \sum_{j=1}^{k} \eta_j^2(\phi_j^*)^2.
\]
with \( \beta' = \min(\beta, (1 + 2p)(1 - \alpha)) \). Without loss of generality, we may assume that \( \beta' \geq 1 - 2\alpha \). By Lemmas 4.2 and 4.3, the first sum is bounded by

\[
\sum_{j=1}^{k} \eta_j^2 d_j^2 \leq e^{-2c\alpha,\beta',1+2s}e^{-(1+2s)(1-\alpha)+\max(0,1-2\alpha-\beta')} + e^{-1}c'_{\alpha,\beta',1}\|B\|k^{-\alpha+\beta'} \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}.
\]

(4.5)

Since \( \beta' + \alpha > \beta \) and \( \max(0,1-2\alpha-\beta') = 0 \), thus,

\[
\sum_{j=1}^{k} \eta_j^2 d_j^2 \leq (e^{-2c\alpha,\beta',1+2s}e^{-(1+2s)(1-\alpha)+\beta'} \ln k + e^{-1}c'_{\alpha,\beta',1}\|B\|k^{-\alpha+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}) k^{-\beta'}.
\]

Meanwhile, with \(- (1+2s)(1-\alpha) + \max(0,1-2\alpha) = - \min((1+2s)(1-\alpha), \alpha + 2s(1-\alpha)) \), we obtain

\[
\sum_{j=1}^{k} \eta_j^2 d_j^2 \leq e^{-2c\alpha,0,2s}e^{-(1+2s)(1-\alpha)+\beta'} \ln k + e^{-1}c'_{\alpha,0,1}\|B\|k^{-\alpha+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'} k^{-\beta'}.
\]

Combining the preceding estimates yields

\[
d_{k+1} \leq (cc_s + 2cp) (e^{-2c\alpha,\beta',1+2s}e^{-(1+2s)(1-\alpha)+\beta'} \ln k + e^{-1}c'_{\alpha,\beta',1}\|B\|k^{-\alpha+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}) k^{-\beta'} + (cc_s + 2c) \delta^2 (e^{-2c\alpha,0,1+2s}e^{-(1+2s)(1-\alpha)+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}) k^{-\beta'}.
\]

Since by assumption, \( \beta < (1+2s)(1-\alpha), \beta < \alpha + \beta' \) and \( \gamma < \min(\alpha,1-\alpha) \), there exists \( k^* \) such that for all \( k \geq k^* \)

\[
(c_s + 2cp) (e^{-2c\alpha,\beta',1+2s}e^{-(1+2s)(1-\alpha)+\beta'} \ln k + e^{-1}c'_{\alpha,\beta',1}\|B\|k^{-\alpha+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}) < \frac{1}{4},
\]

\[
(c_s + 2c) \delta^2 (e^{-2c\alpha,0,1+2s}e^{-(1+2s)(1-\alpha)+\beta'} + \beta' \ln k + c_0^2\|B\|^2k^{-2\alpha+\beta'}) < \frac{1}{4}.
\]

Thus, with this choice of \( k^* \) and \( k \geq k^* \),

\[
d_{k+1} \leq \frac{c}{4} (k^{-\beta'} + \delta^2k^{-\gamma}) \leq c\left\{(k + 1)^{-\beta'} + \delta^2(k + 1)^{-\gamma}\right\} < c\left\{((k + 1)^{-\beta'} + \delta^2(k + 1)^{-\gamma}\right\}
\]

and we obtain the desired assertion.

\[\square\]

**Remark 4.1.** The \( n \) factor in the estimate is due to the variance inflation of using stochastic gradients in place of gradient in SGD. This factor can be reduced by suitable variance reduction technique, e.g., mini-batching and stochastic variance reduced gradient [17]. Note that with [8, Theorems 3.1 and 3.2] and \( s = 0 \), Proposition 4.7 gives an improved (regarding the exponents) a priori bound for the mean squared error \( E[\|x_k - x^*\|^2] \).

Last, using Lemma 4.4 and Proposition 4.1 we can prove Proposition 2.2.

**Proof of Proposition 2.2.** Using Lemma 4.4 and Proposition 4.1 with \( s = \frac{1}{2} \) and \( c = c(\alpha, p, n, s, \beta, \gamma) \), we deduce

\[
E[\|A(x^{(\delta)}_{\kappa(\delta)}) - E[x^{(\delta)}_{\kappa(\delta)}]\|^2] \leq nc(\kappa(\delta) - \beta' + \delta^2\kappa(\delta) - \gamma).
\]

We choose \( \gamma > 0 \). If \( p < \frac{1}{2} \) and \( r > 2p \), then we can choose \( \beta > (1 - \alpha)(2p + 1) \), so with the choice \( \kappa(\delta) = \delta^{-\frac{(1-\alpha)(2p+1)}{r+1}} \), the claim follows. Otherwise, if \( p \geq \frac{1}{2} \), then we can choose \( \beta > (1 - \alpha)(r + 1) \), so with the choice \( \kappa(\delta) = \delta^{-\frac{(1-\alpha)(r+1)}{r+1}} \) the claim again follows. This completes the proof of the proposition.

\[\square\]
5 Numerical experiments and discussions

Now we provide numerical experiments to complement the theoretical analysis. Three model examples, i.e., phillips (mildly ill-posed, smooth), gravity (severely ill-posed, medium smooth) and shaw (severely ill-posed, nonsmooth), are taken from the open source MATLAB package Regutools [6], available at http://people.compute.dtu.dk/pcha/Regutools/ (last accessed on April 14, 2020). The problems cover a variety of setting, e.g., different solution smoothness and degree of ill-posedness. These examples are discretizations of Fredholm/Volterra integral equations of the first kind, by means of either the Galerkin approximation with piecewise constant basis functions or quadrature rules. All the examples are discretized into a linear system of size \( n = m = 1000 \). In addition, we generate a synthetic example, termed smoothed-phillips, whose exact solution \( x^\dagger \) is first generated by \( \tilde{x}^\dagger = A^\dagger A A^\dagger \tilde{y}^\dagger \) and then normalized to have maximum unit, i.e., \( x^\dagger = \tilde{x}^\dagger / \|\tilde{x}^\dagger\|_{\infty} \), where \( A \) is the system matrix and \( \tilde{y}^\dagger \) the exact data from phillips, and the corresponding exact data is formed by \( y^\dagger = A x^\dagger \). By its very construction, the solution \( x^\dagger \) satisfies Assumption 1.1(ii) with an exponent \( p > \frac{3}{2} \), and thus it is very smooth in some sense. Throughout, the noisy data \( y^\delta \) is generated according to

\[
y^\delta_i := y_i^\dagger + \delta \max_j |y_j^\dagger| \xi_i, \quad i = 1, \ldots, n,
\]

where the i.i.d. random variables \( \xi_i \) follow the standard Gaussian distribution (with zero mean and unit variance), and \( \delta > 0 \) denotes the relative noise level (by slightly abusing the notation). The parameter \( \eta_0 \) in the stepsize schedule in Assumption 1.1(i) is set to \((\max_i |a_i|^2)^{-1}\), the exponent \( \alpha \) is taken from the set \( \{0.1, 0.3, 0.5\} \), and unless otherwise stated, the stopping criterion is tested every 100 SGD iterations (see Remarks 2.2 and 3.1). SGD is always initialized with \( x_1 = 0 \), and the maximum number of epochs is fixed at 5000, where one epoch refers to \( n \) SGD iterations. The parameter \( \tau \) in the discrepancy principle (1.3) is fixed at \( \tau = 1.2 \). All the statistical quantities presented below are computed from 100 independent runs.

5.1 Optimality

First, we compare SGD with the classical Landweber method to illustrate the performance of SGD equipped with the discrepancy principle (1.3). The Landweber method is known to be an order optimal regularization method with infinite qualification [3, Theorem 6.5, p. 159], when terminated by the discrepancy principle (2.2), and thus the discrepancy principle (1.3) is fixed at \( \tau = 1.2 \). We also study the Landweber method, terminated with the discrepancy principle (2.2) with \( \tau^* = 1.2 \) (i.e., the same as for SGD) with the maximum number of iterations being fixed at 5000. The numerical results for the examples are summarized in Tables 1–4. In the tables, \( e_{\text{sgd}} \) and \( \text{std}(e_{\text{sgd}}) \) denote the (sample) mean and the (sample) standard deviation of the (squared) error \( \|x_k^\dagger - x^\dagger\|^2 \), respectively, i.e.,

\[
e_{\text{sgd}} = \mathbb{E}[\|x_k^\dagger - x^\dagger\|^2] \quad \text{and} \quad \text{std}(e_{\text{sgd}}) = \mathbb{E}[\|x_k^\dagger - x^\dagger\|^2 - e_{\text{sgd}}^2]^\frac{1}{2},
\]

and \( k_{\text{sgd}} = \mathbb{E}[k_j^\dagger] \) is the mean stopping index for SGD, in terms of the number of epochs. Likewise \( e_{\text{lm}} \) and \( k_{\text{lm}} \) denote the squared reconstruction error and stopping index, respectively, of the Landweber method, terminated according to the discrepancy principle (2.2).

| Table 1: Comparison between SGD and LM for phillips. |
|---|---|---|---|---|
| | \( \delta \) | \( \alpha = 0.1 \) | \( \alpha = 0.3 \) | \( \alpha = 0.5 \) | LM |
| \( 1e-3 \) | 7.44e-3 | 4.40e-3 | 2.568 | 6.48e-3 | 3.79e-3 | 12.64 | 6.23e-3 | 2.69e-3 | 336.1 | 5.72e-3 | 361.0 |
| \( 5e-3 \) | 1.61e-2 | 8.77e-3 | 0.576 | 1.87e-2 | 8.42e-3 | 1.390 | 2.03e-2 | 8.17e-3 | 10.08 | 2.26e-2 | 128.0 |
| \( 1e-2 \) | 2.51e-2 | 1.39e-2 | 0.287 | 3.57e-2 | 1.68e-2 | 0.487 | 3.93e-2 | 1.69e-2 | 2.150 | 5.76e-2 | 51.0 |
| \( 5e-2 \) | 1.14e-1 | 7.47e-2 | 0.150 | 1.42e-1 | 7.88e-2 | 0.118 | 1.79e-1 | 9.55e-2 | 0.161 | 2.19e-1 | 15.0 |

11
The numerical results allow drawing a number of interesting observations. First, the exponent $\alpha$ in the stepsize schedule exerts a strong influence on the (expected) stopping index $k_{\text{sgd}}$. At low noise levels (i.e., small $\delta$), $k_{\text{sgd}}$ increases dramatically with the value of $\alpha$. Meanwhile, for any fixed $\alpha$, the error $\epsilon_{\text{sgd}}$ increases steadily with the noise level $\delta$, exhibiting the convergence behavior indicated in Theorem 1.2. Further, for each fixed $\delta$, the error $\epsilon_{\text{sgd}}$ is largely comparable for all different $\alpha$ values, although $k_{\text{sgd}}$ increases with $\alpha$. This behavior is qualitatively in good agreement with Theorem 1.1: the upper bound scales as $O(\delta^{-\alpha/(\alpha+2)})$. Thus, in practice, in order to obtain relatively efficient SGD, one prefers small $\alpha$ values. Second, in terms of accuracy (measured by the mean squared error), SGD is competitive with the classical Landweber method for phillips, gravity and shaw: $\epsilon_{\text{sgd}}$ and $\epsilon_{\text{lm}}$ are fairly close to each other in most cases, and $\epsilon_{\text{sgd}}$ can be smaller than $\epsilon_{\text{lm}}$, which fully confirms the order-optimality of the discrepancy principle (1.3) for SGD for low regularity solutions, and also confirming the convergence in Theorem 1.2. In fact, empirically, the error seems to converge not only in probability, but also in $L^2$. A close inspection on the stopping index $k_{\text{sgd}}$ is very telling: when the noise level $\delta$ is medium to large, the stopping index $k_{\text{sgd}}$ of SGD, determined by (1.3), is ten-fold smaller than that for the Landweber method in terms of epoch count. In particular, when the noise level $\delta$ is relatively high, SGD can actually deliver an accurate solution within less than one epoch, i.e., going through only a small fraction of all the available data points. Thus, in this regime, SGD is much more efficient than the Landweber method. These observations are valid for all the examples, despite their dramatic difference in degree of ill-posedness and solution smoothness. However, for smoothed-phillips, the achieved accuracy by SGD is far below that by the Landweber method for all three exponents $\alpha$. This suboptimality in convergence rate is attributed to the saturation phenomenon for SGD, due to the dominance of the computational variance, when the true solution $x^\dagger$ is very smooth. The effect of the variance component will be examined more closely below in Section 5.2.

The example shaw is challenging for numerical recovery, since the solution is far less smooth, and at low noise level $\delta = 1e-3$, the discrepancy principle (2.2) cannot be reached even after 5000 Landweber iterations, see Table 3.

The example shaw is challenging for numerical recovery, since the solution is far less smooth, and at low noise level $\delta = 1e-3$, the discrepancy principle (2.2) cannot be reached even after 5000 Landweber iterations, see Table 3.
A similar behavior is also observed for SGD with \( \alpha = 0.3 \) and \( \alpha = 0.5 \). Nonetheless, with \( \alpha = 0.1 \), the discrepancy principle \([1, 3]\) can be reached by SGD after a few hundred epochs, clearly showing the surprisingly beneficial effect of SGD noise for low-regularity solutions.

Next we examine more closely the behavior of individual samples. The boxplots are shown in Fig. 1 for the examples at two different scenarios, i.e., fixed \( \alpha \) and fixed \( \delta \). On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively: The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol. It is observed that for a fixed \( \alpha \), on average the error \( \|x_k^\delta - x^\dagger\|_2^2 \) increases with the noise level \( \delta \) smoothly, and also its distribution broadens accordingly. However, the required number of iterations to fulfill the discrepancy principle \([1, 3]\) decreases dramatically, as the noise level \( \delta \) increases, concuring with the preceding observation that SGD is especially efficient for data with high noise levels. Meanwhile, with the noise level \( \delta \) fixed, the value of \( \alpha \) does not change the results much overall. However, a larger \( \alpha \) can potentially make the percentile box larger and also more outliers, as shown by the results for gravity in Fig. 3 and thus give less accurate results. This observation is counter-intuitive in that smaller variance does not immediately lead to better accuracy. This might be related to the delicacy of the interplay between the total error and various problem / algorithmic parameters, e.g., \( \alpha \) and \( \rho \). Further, the outliers in the boxplots mostly lie above the box. These observations are typical for all the examples.

5.2 How influential is the variance?

Now we examine more closely the dynamics of the SGD iteration via the bias-variance decomposition of the error \( \mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2] \) and residual \( \mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2] \):

\[
\mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2] = \mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2 + \mathbb{E}[\|x_k^\delta - \mathbb{E}[x_k^\delta]\|_2^2],
\]

\[
\mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2] = \mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2 + \mathbb{E}[\|A(x_k^\delta - \mathbb{E}[x_k^\delta])\|_2^2].
\]

In Fig. 2 we display the dynamics of mean squared error \( \mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2] \) and the mean squared residual \( \mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2] \) together with their variance components for the examples at two different relative noise levels, i.e., \( \delta = 5 \times 10^{-3} \) and \( \delta = 5 \times 10^{-2} \). At each time, SGD is run for 100 epochs (i.e., \( 15 \) SGD iterations), and the results are recorded every 50 SGD iterations, starting from the 50th SGD iteration.

In the plots, we have indicated the true noise \( \|y^\delta - y^\dagger\|_2 \), also denoted by \( \delta^2 \). It is observed that both \( \mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2] \) and \( \mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2] \) decay steadily at an algebraic rate up to a value comparable to the stopping index \( k^*(\delta) \) for the Landweber method (by the discrepancy principle \([2, 2]\)). Beyond the critical threshold \( k^*(\delta) \), the error \( \mathbb{E}[\|x_k^\delta - x^\dagger\|_2^2] \) exhibits a semiconvergence behavior in that it starts to increase, whereas the residual \( \mathbb{E}[\|Ax_k^\delta - y^\delta\|_2^2] \) nearly levels off at a value comparable to the stopping value \( \delta^2 \) (actually it oscillates slightly, since the SGD iterate is only descent for the residual on average). This is typical for iterative regularization methods for inverse problems, since for the later iterates, the noise becomes the dominating driving force. Proposition 4.1 with \( \alpha = \frac{1}{3} \) indicates that a similar behavior holds also for their variance components (up to slightly beyond \( k^*(\delta) \)). Actually, the residual variance \( \mathbb{E}[[\|A(x_k^\delta - \mathbb{E}[x_k^\delta])\|_2^2] \) first decays as \( O(k^{-2(1-\alpha)}) \) (upon ignoring the \( \delta \) term), which matches well the empirical rate in the plot. For the later iterates, as suggested by the \( \delta \) term in Proposition 4.1, the decay is roughly \( O(k^{-\alpha}) \). Likewise, the error variance \( \mathbb{E}[[\|x_k^\delta - \mathbb{E}[x_k^\delta]\|_2^2] \) decays slower at a rate \( O(k^{-(1-\alpha)}) \). Interestingly, the decay rates of \( \mathbb{E}[[\|A(x_k^\delta - \mathbb{E}[x_k^\delta])\|_2^2] \) and \( \mathbb{E}[[\|x_k^\delta - \mathbb{E}[x_k^\delta]\|_2^2] \) in the first and last columns are largely comparable, despite their drastic difference in the smoothness of the exact solution \( x^\dagger \). Thus, the decay estimate in Proposition 4.1 is actually quite sharp, partially explaining the saturation phenomenon observed earlier. This behavior is consistently observed for all three \( \alpha \) values. It is worth noting that for smoothed-phillips, the curves for \( \mathbb{E}[[\|x_k^\delta - \mathbb{E}[x_k^\delta]\|_2^2] \) and \( \mathbb{E}[[\|x_k^\delta - x^\dagger\|_2^2] \) nearly overlay each other, i.e., the bias component is negligible after the initial 50 iterations, due to high smoothness of the true solution, clearly indicating the saturation. For the other three examples, empirically, the variance components are of smaller order right after the initial 50 iterations. In particular, as stated in Proposition 2.2, \( \mathbb{E}[[\|A(x_k^\delta - \mathbb{E}[x_k^\delta])\|_2^2] \) contributes very little to the mean squared residual \( \mathbb{E}[[Ax_k^\delta - y^\delta]\|_2^2] \) in the neighborhood of \( k^*(\delta) \). This occurs for all three values of the exponent \( \alpha \) in the stepsize schedule. The observations hold also for individual realizations; see Fig. 3 for the corresponding plots. The overall behavior of the curves in Fig. 3 is fairly similar to that in Fig. 2 except that the residual and error curves exhibit pronounced oscillations due to the randomness of the row index selection. Nonetheless, in the neighborhood of
Figure 1: Box plots for the error $\|x_{k_\delta}^\delta - x^\delta\|^2$ and the stopping index $k_\delta$ by SGD. The first two columns are obtained by SGD with $\alpha = 0.3$, whereas the last two columns are for the noise level $\delta = 1e-2$. The rows from top to bottom refer to phillips, gravity, shaw and smoothed-phillips, respectively.

$k^*(\delta)$, the variance components remain much smaller in magnitude. This observation provides the key insight for the analysis in Section 2.

5.3 Independent run

The convergence analysis in Theorem 1.2 requires a SGD iterate $x_{k_\delta}^\delta$ independent of the stopping index $k(\delta)$ determined by the discrepancy principle (1.3). In practice this can be achieved by an independent run of SGD, at the expense of slightly increasing the computational effort. Now we examine the impact of this choice, and we denote by DP and i-DP the SGD iterate used in (1.3) and that by an independent SGD run, respectively. The relevant numerical results are presented in Tables 5–7, where the numbers outside and inside the bracket denote
Figure 2: The decay of the mean squared error $E[\|x_k^\delta - x^\dagger\|^2]$ and residual $E[\|Ax_k^\delta - y^\delta\|^2]$ and their variance components $E[\|x_k^\delta - E[x_k^\delta]\|^2]$ and $E[\|A(x_k^\delta - E[x_k^\delta])\|^2]$ versus the SGD iteration number $k$. The solid and dashed curves denote the mean squared quantity and the variance component, respectively, and the black curve indicates the discrepancy $\delta^2 = \|y^\delta - y^\dagger\|^2$. The first two columns are for the noise level $\delta = 5e-3$ and the last two columns are for the noise level $\delta = 5e-2$. The rows from top to bottom refer to phillips, gravity, shaw and smoothed-phillips, respectively.
Figure 3: The decay of the squared error $\|x^*_k - x^\dagger\|^2$ and residual $\|Ax^*_k - y^\dagger\|^2$ and their variance components $E[\|x^*_k - E[x^*_k]\|^2]$ and $E[\|A(x^*_k - E[x^*_k])\|^2]$ versus the SGD iteration number $k$. The solid and dashed curves denote the squared quantity and the variance components, respectively, and the black curve indicates the discrepancy $\delta^2 = \|y^\dagger - y^\delta\|^2$. The first two columns are for the noise level $\delta = 5e-3$ and the last two columns are for the noise level $\delta = 5e-2$. The rows from top to bottom refer to phillips, gravity, shaw and smoothed-phillips, respectively.
It is observed that DP gives only slightly better results in terms of the mean, but its standard deviation \( \text{std}(\varepsilon_{\text{sgd}}) \) is generally much smaller than that by i-DP. Nonetheless, both the mean \( \varepsilon_{\text{sgd}} \) and the standard deviation \( \text{std}(\varepsilon_{\text{sgd}}) \) of i-DP are decreasing steadily as the noise level \( \delta \) decreases to 0, confirming the convergence result in Theorem 1.2.

The difference is more clearly visualised in the boxplots in Fig. 4 (for phillips with two noise levels). A close look shows that the mean and percentile are fairly close to each other, but the i-DP result tends to have far more outliers lying above the box (marked by red cross in the plots). This is attributed to the fact that \( k(\delta) \) determined by the discrepancy principle (1.3) is occasionally too small for an independent SGD run, and thus the corresponding residual is far above the target noise level in the discrepancy principle (1.3); see the boxplots in the last column of Fig. 4. That is, the outliers are due to stopping too early. This agrees with the observation that one iteration step of SGD has only a small effect on the high frequency components (because of the scaling with the corresponding small singular values). Thus, small \( \|Ax_k^\delta - y^\dagger\| \) for \( k \ll k^*(\delta) \) implies that also \( \|x_k^\delta - x^\dagger\| \) is small. Although not presented, we note that this behavior is observed for all the examples at different noise levels. Thus, in practice, using the SGD iterate directly from the path for (1.3) is preferred, taking into account both accuracy and computational efficiency. It is an interesting theoretical question to analyze the convergence (and convergence rates) of the SGD iterate by (1.3).

### Table 5: Comparison between DP and i-DP for phillips.

| \( \delta \) | \( \alpha = 0.1 \) | \( \alpha = 0.3 \) | \( \alpha = 0.5 \) |
|---|---|---|---|
| DP | i-DP | DP | i-DP | DP | i-DP |
| 1e-3 | 7.44e-3 (4.40e-3) | 9.10e-3 (9.49e-3) | 6.48e-3 (3.79e-3) | 9.68e-3 (1.13e-2) | 6.23e-3 (2.69e-3) | 1.11e-2 (3.33e-2) |
| 5e-3 | 1.61e-2 (8.77e-3) | 2.34e-2 (2.29e-2) | 1.87e-2 (8.42e-3) | 2.79e-2 (2.47e-2) | 2.03e-2 (8.17e-3) | 3.68e-2 (1.06e-1) |
| 1e-2 | 2.51e-2 (1.39e-2) | 4.44e-2 (5.39e-2) | 3.57e-2 (1.68e-2) | 5.17e-2 (4.63e-2) | 3.93e-2 (1.69e-2) | 7.05e-2 (9.16e-2) |
| 5e-2 | 1.14e-1 (7.47e-2) | 1.51e-1 (8.35e-2) | 1.42e-1 (7.88e-2) | 1.80e-1 (1.15e-1) | 1.79e-1 (9.55e-2) | 2.48e-1 (1.71e-1) |

### Table 6: Comparison between DP and i-DP for gravity.

| \( \delta \) | \( \alpha = 0.1 \) | \( \alpha = 0.3 \) | \( \alpha = 0.5 \) |
|---|---|---|---|
| DP | i-DP | DP | i-DP | DP | i-DP |
| 1e-3 | 9.22e-1 (1.46e-1) | 1.02e0 (3.38e-1) | 9.23e-1 (1.52e-1) | 1.00e0 (4.23e-1) | 1.09e0 (1.68e-1) | 1.11e0 (2.21e-1) |
| 5e-3 | 2.58e0 (7.45e-1) | 3.15e0 (1.66e0) | 2.85e0 (6.29e-1) | 3.33e0 (1.95e0) | 2.84e0 (6.36e-1) | 3.40e0 (1.76e0) |
| 1e-2 | 4.01e0 (1.37e0) | 5.06e0 (3.83e0) | 5.04e0 (1.44e0) | 7.80e0 (7.49e0) | 4.91e0 (1.49e0) | 6.55e0 (4.36e0) |
| 5e-2 | 1.23e1 (6.78e0) | 1.31e1 (7.61e0) | 1.35e1 (6.26e0) | 1.45e1 (9.85e0) | 1.65e1 (6.22e0) | 1.58e1 (9.30e0) |

### Table 7: Comparison between DP and i-DP for shaw.

| \( \delta \) | \( \alpha = 0.1 \) | \( \alpha = 0.3 \) | \( \alpha = 0.5 \) |
|---|---|---|---|
| DP | i-DP | DP | i-DP | DP | i-DP |
| 1e-3 | 8.22e0 (6.11e-2) | 8.21e0 (2.13e-1) | 1.52e1 (2.19e-1) | 1.52e1 (1.85e-1) | 2.87e1 (4.99e-1) | 2.87e1 (4.41e-1) |
| 5e-3 | 3.30e1 (1.29e0) | 3.29e1 (1.31e0) | 3.31e1 (1.09e0) | 3.32e1 (1.14e0) | 3.21e1 (8.85e-1) | 3.21e1 (9.98e-1) |
| 1e-2 | 3.45e1 (1.55e0) | 3.45e1 (2.08e0) | 3.52e1 (1.24e0) | 3.55e1 (1.49e0) | 3.51e1 (8.58e-1) | 3.54e1 (1.33e0) |
| 5e-2 | 6.55e1 (1.21e1) | 6.90e1 (2.12e1) | 7.75e1 (8.72e0) | 8.20e1 (1.84e1) | 8.24e1 (6.27e0) | 8.53e1 (1.57e1) |
