Abstract
Application of nanoscience in phytopathology has shown a rapid progress in recent days. Nanoparticles applied through seed treatment improves seed germination, growth and seedling vigour along with its properties of antimicrobial effect. In the present study, influence of four nanoformulations viz. chitosan based zinc, *Pseudomonas fluorescens* based zinc, pomegranate aril based sulphur and pomegranate aril based silver nanoformulation was assessed on soybean seed quality parameters. All four nanoformulation promoted germination per cent, seedling length, seedling vigour and dry weight. Pomegranate aril based silver nanoformulation @500 ppm was found best because, it suppressed fungal infection (97.33%) during germination effectively in addition to positive influence on seedling growth (seedling vigour index- 2831), which is on par with Carboxin 37.5% + Thiram 37.5% DS (2 g/Kg of seed) fungicide. A trend of decreasing germination per cent and seedling vigour index of soybean JS 335 seeds were observed while using higher concentration (above 1000 ppm) of pomegranate aril based sulphur nanoformulation due to its toxicity. Further, these results can be efficiently utilized in choosing nanoformulation for management of diseases.

Keywords: Nanoformulation, seed quality parameters, soybean, fungal infection

Introduction
Nanotechnology, in recent days has been widely adapted in different fields of science. One such extensively explored field is agriculture. The agricultural sector has set in motion research on this technology to develop agricultural inputs and resources. Nanotechnology studies in phytopathology have developed exponentially over last decade. The topic of nanotechnology deals with synthesis, analysis and manipulation of nano-scale matter within the size range of 1-100 nm, which is called as nanoparticle (Rajan, 2004) [6]. Application of nanotechnology in Plant Pathology is a state of art and science that are used for treatment and control of plant diseases and their causal organisms by avoiding disease epidemics. Soybean (*Glycine max* (L.)), a legume species is a cheap and rich protein source. It is also an important oilseed crop grown in diverse climatic conditions of India. The main approach for management of different diseases of soybean is use of chemicals. The environmental hazardous nature of chemicals always led to the search of alternative management strategies. Nanofungicide is such one alternative which is a leading strategy in recent days. In addition to disease controlling ability, nanofungicides should not have negative impact on growth of seedlings. It is said be best if it positively contributes to the seedling growth. In this regard, synthesized nanoformulation along with the base materials used for synthesis was used in soybean seed treatment to study the impact of the formulation on germination, reduction in fungal infection and seedling vigour. The results are discussed in this paper.

Material and methods
Chitosan and *Pseudomonas fluorescens* based zinc nanoparticles synthesized by following procedure of Vinay et al. (2016) [10] and Vinay et al. (2018) [11] respectively along with pomegranate aril based silver and sulphur nanoparticles synthesized by following Srikanth (2018) were tested for its efficacy on germination of JS 335 variety of soybean seed and control of fungal infection. In addition effect of nanoparticles on seedling vigour was assessed.
The effect of seed treatment with four nanoparticles along with base materials and standard check fungicide on soybean seed germination and seedling vigour index was studied by adopting the procedure of ‘Between Paper’ (Rolled towel paper) as described by ISTA rules (Anon., 1999) [2]. The soybean seeds were soaked in various concentration of different nanoparticle (as detailed in table 1) for 5 minutes and dried on a blotter paper. Randomly selected 400 seeds from the treatment were placed in between four pairs of moist germination paper and rolled with a plastic cover. This was placed in germination chamber at 26 ⁰C and 95 per cent Relative humidity. Germination percentage, fungal infection, shoot and root length was recorded for three replication of each treatment after 8 days. Seedling vigour index was calculated by the following formula, given by Abdul Baki and Anderson (1973) [1]

Seedling Vigour Index = Seed germination (%) × Seedling length (Shoot + Root length (cm))

Further 10 seedlings were taken from each treatment, dried in hot air oven at 75 ⁰C for 2-3 days and weight was recorded. Three replications were maintained.

Results and discussion
The seed treatment effect of Chitosan based zinc, Pseudomonas fluorescens based zinc, Pomegranate aril based sulphur and silver nanoformulations on soybean seed quality parameters viz. germination, fungal infection (Table 1), seedling vigour and dry weight (Table 2) has discussed below in detail.

Effect of nanoformulations on germination and fungal infection
Germination of JS 335 seeds of soybean among different tested concentration of nanoformulation varied from 94 to 99.67 per cent. Carboxin 37.5% + Thiram 37.5% DS (2 g/Kg of seed), a chemical fungicide resulted in 99.67 per cent germination which was on par with all four nanoformulation and lowest was observed in control. Pomegranate aril based silver nanoformulation at 500 ppm concentration suppressed fungal infection (Aspergillus spp.) effectively to the extent of 97.33 per cent against 77 per cent in control. This treatment is on par with Carboxin 37.5% + Thiram 37.5% DS (2 g/Kg of seed) treatment with 98.33 percent reduction. These two treatments significantly differed from all other treatments. Nanoformulations treatments among them are, chitosan and Pseudomonas fluorescens based zinc nanoformulations at 1000, 1250 and 1500 ppm, pomegranate aril based sulphur nanoformulation at 1500 and 2000 ppm, and pomegranate aril based silver nanoformulation at all four concentration. A lowest seedling vigour index of 2123.33 was recorded in control. Seedling dry weigh varied from 0.64g (Pomegranate aril based silver nanoformulation @ 50 ppm) to 0.87g (Pseudomonas fluorescens based zinc nanoformulation @1500 ppm). Similar observations were recorded by Hojjat (2015) [4] and Supriya (2019) [9] where seed treatment with silver nanoparticles resulted in improvement of seed germination per cent, seedling vigour index and dry weight in fenugreek and soybean respectively. The result is also in agreement with the experimental result of Hao et al. (2016) [3] who reported the significant promotion of root and shoot length with the treatment of iron and titanium nanoparticles in rice seeds and also observed non obvious effect on weight. A decrease in seedling vigour index was observed in pomegranate aril based nanoformulation after 1000 ppm concentration. This result was in accordance with the observation found by Salem et al. (2016) [7], who observed an inhibitory effect of sulphur nanoparticle on tomato seeds beyond 300 ppm concentration.

Table 1: Effect of seed treatment of nanoformulation on germination per cent and fungal infection rate in soybean

| Treatments | Concentration | Germination percentage (%) | Fungal infection (%) |
|------------|---------------|-----------------------------|-----------------------|

*Values are mean of three replication
Figures in parenthesis are square root transformed value

**Plate 1:** Effect of different nanoformulation on seedling growth

**Conclusion**
Nanotechnology application in phytopathology has been widely spreading globally. In this view, an attempt was made to analyze the effect of chitosan and *Pseudomonas* based zinc nanoformulation and pomegranate aril based sulphur and silver nanoformulation on soybean seed quality parameters. All four nanoformulation, promoted germination shoot length, root length, seedling vigour. Pomegranate aril based silver nanoformulation, not only showed positive effect on seedling vigour, but also suppressed fungal pathogens effectively. Thus, this treatment was found to be best. These nanoformulations can be further effectively used for management of various phytopathogens as they promote and strengthen the seedling in addition to pathogen suppression.
