One of the most crucial domains of interdisciplinary research is the relationship between the dynamics and structural characteristics. In this paper, we introduce a family of small-world networks, parameterized through a variable controlling the scale of graph completeness or of network clustering. We study the Laplacian eigenvalues of these networks, which are determined through analytic recursive equations. This allows us to analyze the spectra in depth and to determine the corresponding spectral dimension. Based on these results, we consider the networks in the framework of generalized Gaussian structures, whose physical behavior is exemplified on the relaxation dynamics and on the fluorescence depolarization under quasiresonant energy transfer. Although the networks have the same number of nodes (beads) and edges (springs) as the dual Sierpinski gaskets, they display rather different dynamic behavior.

One of the most major problems in the study of networks is to understand the relations between their topology and the dynamics. For instance, in the framework of generalized Gaussian structures (GGSs), the dynamics of polymer networks is fully described through the Laplacian eigenvectors and eigenvalues. In the field of GGSs and dynamical processes, the investigation of Laplacian eigenmodes has a paramount importance for the relaxation dynamics, the fluorescence depolarization by quasiresonant energy transfer, the mean first-passage time problems, and community structure. Laplacian eigenvalues and eigenvectors play an irreplaceable role and they are also relevant to multi-aspects of complex network structures, like spanning trees, resistance distance, and community structure. However, it is a challenging task to derive exact Laplacian eigenvalues or eigenvectors for a complex system and based on them to describe its dynamics. We remark that for this the use of deterministic structures is of much help. Although the structural disorder leads in case of many real networks like hyperbranched polymers to smoothing-out and averaging, the topological features are still reflected in the typical scaling behaviors. Furthermore, recently a striking development of chemistry made possible the synthesis of the hierarchical, fractal Sierpinski-type compounds. Undoubtedly, this new achievement will keep the interest of the theorists on the regular structures, especially on those with loops.

The study of Laplacian eigenvalues has exhibited its activity during the past few decades, among extensive subjects and researches. The works from last century had solved the Laplacian eigenvalues for considerable amount of famous networks, like dual Sierpinski gaskets (in 2 or higher dimensions), dendrimers, and Vicsek fractals. Another type of model structures, which often arise in the complex systems or polymer networks, are the so-called small-world networks (SWNs). Recent studies have also suggested that SWNs play a notable role in real life.

In this report we introduce a new kind of SWNs. Their construction is based on complete graphs consisting of nodes and they have the same number of nodes and of edges as the dual Sierpinski gaskets embedded in (d − 1)-dimension. A complete graph is a simple undirected graph in which every pair of distinct vertices is connected by a unique edge. It has been widely used in quantum walks, tensor networks, social networks, and explosive percolation problem. While the SWNs introduced here are based on complete graph, their clustering coefficient shows that the SWNs are similar to complete graphs only in the limit \( d \to \infty \). As we proceed to show, also in this limit they have similar behavior as the dual Sierpinski gaskets embedded in to \( d \to \infty \) dimensions. On the other hand, for finite \( d \), the SWNs display a macroscopically distinguishable behavior.

The report is organized as follows: First, we present the construction of SWNs, analyze their properties and their Laplacian spectra (the derivation of the recursive equations for the eigenvalues is given in Methods). Then,
based on the spectra we consider the dynamics of networks, namely, the structural average of the mean monomer displacement under applied constant force and the mechanical relaxation moduli, and the dynamics on networks, exemplified through the fluorescence depolarization. Finally, we summarize and discuss our results.

**Results**

**Model structures.** We start with a brief introduction to a family of small-world networks (SWNs) $\Omega^d_g$ characterized by two parameters $d$ and $g$, where $d$ stands for the number of nodes of complete graph and $g$ for the current generation. Figure 1 shows a construction process from $\Omega^1_g$ to $\Omega^2_g$. At first, $\Omega^1_g$ is a simple triangle, that is, a complete graph with 3 nodes. At the next stage, each node in $\Omega^2_g$ is replaced by a new complete graph. Thus each of the newly appeared complete graphs contains exactly one node of $\Omega^1_g$ and we get the network at second generation $\Omega^3_g$. The growth process to the next generation continues in a similar way: Connecting a complete graph to each of the node of $\Omega^3_g$ one gets $\Omega^3_g$. In general, we have $d^{1}\text{ nodes at generation } g-1$. By attaching $d-1$ nodes to each existing node, increases their total number from $d^{1}$ to $d^{2}$. In this way, we get immediately the number of nodes in this network, $N^d_g = d^g$, and the number of edges, $E^g = \frac{1}{2}(d^{g+1} - d)$. It has to be mentioned that the dual Sierpinski gaskets embedded in $(d - 1)$-dimension have exactly the same number of nodes and of edges.\(^5\)

To give evidence of the small-world property, we consider another characteristics, the diameter of the network. For a network, the diameter of the network increases by 2 at most. Then the diameter of the network increases by 2 at most. Finally, we summarize and discuss our results.

**Results**

**Model structures.** We start with a brief introduction to a family of small-world networks (SWNs) $\Omega^d_g$ characterized by two parameters $d$ and $g$, where $d$ stands for the number of nodes of complete graph and $g$ for the current generation. Figure 1 shows a construction process from $\Omega^1_g$ to $\Omega^2_g$. At first, $\Omega^1_g$ is a simple triangle, that is, a complete graph with 3 nodes. At the next stage, each node in $\Omega^2_g$ is replaced by a new complete graph. Thus each of the newly appeared complete graphs contains exactly one node of $\Omega^1_g$ and we get the network at second generation $\Omega^3_g$. The growth process to the next generation continues in a similar way: Connecting a complete graph to each of the node of $\Omega^3_g$ one gets $\Omega^3_g$. In general, we have $d^{1}\text{ nodes at generation } g-1$. By attaching $d-1$ nodes to each existing node, increases their total number from $d^{1}$ to $d^{2}$. In this way, we get immediately the number of nodes in this network, $N^d_g = d^g$, and the number of edges, $E^g = \frac{1}{2}(d^{g+1} - d)$. It has to be mentioned that the dual Sierpinski gaskets embedded in $(d - 1)$-dimension have exactly the same number of nodes and of edges.\(^5\)

To give evidence of the small-world property, we consider another characteristics, the diameter of the network. For a network, the diameter of the network increases by 2 at most. Then the diameter of the network increases by 2 at most. Finally, we summarize and discuss our results.

**Recursion formulae for the Laplacian spectrum.** Let $A^d_g = [A_{ij}]_{d \times d}$ denote the adjacency matrix of $\Omega^d_g$, where $A_{ij} = 1$ if nodes $i$ and $j$ are adjacent, $A_{ij} = 0$ otherwise, then the degree of node $i$ is $d_i = \sum_{j \neq i} A_{ij}$. Let $D^d_g = \text{diag}(d_1, d_2, \ldots, d_d)$ denote the diagonal degree matrix of $\Omega^d_g$, then the Laplacian matrix of $\Omega^d_g$ is defined by $L^d_g = D^d_g - A^d_g$.

To get a solution for the eigenvalues of $L(\Omega^d_g)$, we have to concentrate our attention on its characteristic polynomial, $P^d(\lambda)$. Here we just give a result and put off the proof and details in Methods:

$$P^d(\lambda) = \det(\lambda I - L(\Omega^d_g)) = (\lambda - 1)^{d-1}(\lambda - d)^{(d-2)^{d-1}} P^d_{d-1} \left( \frac{\lambda - d}{\lambda - 1} \right).$$

The recursion relation provided in equation (4) determines the eigenvalues of Laplacian matrix for $\Omega^d_g$. Note that $P^d_d$ has a factor

Figure 1 | Construction of $\Omega^d_g$ for $d = 3$ and $g = 1$ (blue beads), $g = 2$ (blue and green beads), $g = 3$ (all beads).

Figure 2 | Clustering coefficients of $\Omega^d_g$ for the parameters $d$ from 3 to 6, when $g$ varies from 1 to 100.

$$C_x = \frac{2c_x}{k_x(k_x - 1)} = \frac{d - 2}{h(d - 1) - 1}. \quad (1)$$

Based on equation (1) we can list the correspondence between each kind of clustering coefficient and the corresponding amount of nodes:

$$C_i = \begin{cases} 
1 & \text{for (d - 1)^{d-1} nodes,} 
\frac{d - 2}{2(d - 1) - 1} & \text{for (d - 1)^{d-2} nodes,} 
\vdots & \vdots 
\frac{d - 2}{g(d - 1) - 1} & \text{for (d - 1)^{d-2} nodes,} 
\end{cases} \quad (2)$$

where the last situation represents the center of the whole network. Then we can obtain the average clustering coefficient of all the nodes, $\langle C \rangle = \frac{1}{N^d_g} \sum_{i = 1}^{N^d_g} C_i$.

Based on the spectra we consider the dynamics of networks, namely, the structural average of the mean monomer displacement under applied constant force and the mechanical relaxation moduli, and the dynamics on networks, exemplified through the fluorescence depolarization. Finally, we summarize and discuss our results.
It is evident that \( \Omega^d_{\lambda} \) has \( \lambda \) Laplacian eigenvalues, denoted by \( \lambda_1^\ell, \lambda_2^\ell, \ldots, \lambda_{d^\lambda}\), where \( \ell = 1, 2, \ldots, d^\lambda \), and \( \lambda^\ell \) is the \( \ell \)th eigenvalue in the interval \([0, \lambda]\). Hence, the density of states (modes) \( \rho(\lambda) \) for \( \lambda \ll 1 \) obeys

\[
N \rho(\lambda) \Delta \lambda = dN \rho(\lambda/d) \Delta \lambda/d, \quad \text{i.e. } \rho(\lambda) = \rho(\lambda/d).
\]

Using now the relation between \( \rho(\lambda) \) and the spectral dimension \( d_s \),

\[
\rho(\lambda) \sim \lambda^{d_s/2-1}
\]

leads to

\[
d_s/2-1 = 1.
\]

This means that the spectral dimension of the networks \( \Omega^d_{\lambda} \) is \( d_s = 2 \) and \( d_s \) is independent on \( d \). We note that for the dual Sierpinski gasket embedded in \((d-1)\)-dimension the spectral dimension is \( d = 2 \ln(d)/\ln(d+2) \), see e.g. Refs. 37, 38, i.e. it is similar to that of \( \Omega^d_{\lambda} \) only in the limit \( d \to \infty \).

Dynamics of polymer networks under external forces. We are going to study the networks \( \Omega^d_{\lambda} \) under the framework of generalized Gaussian structures (GGS)\(^{5,6}\), an extension of the classical Rouse beads-springs models\(^{2,39-41}\). Here we let all \( N \) beads of the GGS to be assigned to the same friction constant, \( \zeta \). The beads are connected to each other by elastic springs with spring constant \( K \).

The Langevin equation of motion for the nth bead in a system reads

\[
\zeta \frac{dR_m(t)}{dt} + K \sum_{i=1}^{N} L_{m,i} R_i(t) = f_m(t) + F_m(t),
\]

where \( R_m(t) = (X_m(t), Y_m(t), Z_m(t)) \) is the position vector of the nth bead at time \( t \), \( L \) describing the Laplacian matrix of the \( \Omega^d_{\lambda} \). Moreover, \( f_m(t) \) is the thermal noise that is assumed to be Gaussian with zero mean value \( \langle f_m(t) \rangle = 0 \) and \( \langle f_m(t) f_m(t') \rangle = 2k_B T \delta(t-t') \), where \( k_B \) is the Boltzmann constant, \( T \) is the temperature, \( x, y, z \) represent the coordinates, \( X_m(t) \) and \( Y_m(t) \) are the external forces on the bead \( m \).

First, we consider a quantity which is related to the micromotions with the polymer networks\(^{42}\). We put a constant external force \( F\Theta(t) = F\Theta(0) \delta(t) \delta_{m,m'} (\delta(x-\zeta)) \), which started to act at \( t = 0 \) (the Heaviside step function) on a single bead \( m \) of the \( \Omega^d_{\lambda} \) in the \( y \) direction. After averaging over all possibilities of choosing this monomer randomly, the displacement reads\(^{43,49}\)

\[
\langle Y(t) \rangle = \frac{F t}{N \zeta} + \frac{F}{\sigma \zeta^2} \sum_{i=1}^{N} \frac{1 - \exp(-\sigma \lambda_i t)}{\lambda_i},
\]

where \( \sigma = K/\zeta \) is the bond rate constant, and \( \lambda_i \) is the eigenvalues of matrix \( L \) with \( \lambda_i \) being the unique smallest eigenvalue 0.

Another example is the response to harmonically applied forces (strain fields), i.e. \( F_m(t) = v_0 \cos(\omega t) e_i \). The related response function is the so-called complex dynamic modulus \( G^*(\omega) \), or equivalently, its real \( G'(\omega) \) and imaginary \( G''(\omega) \) components (the storage and the loss moduli\(^{40,41}\)). In the GGS model (for very dilute theta-solutions) the \( G'(\omega) \) and \( G''(\omega) \) are given by

\[
G'''(\omega) = \frac{v k_B T}{N} \sum_{i=1}^{N} \frac{\langle (\omega/2\sigma \lambda_i)^2 \rangle}{1 + \langle (\omega/2\sigma \lambda_i)^2 \rangle^2}
\]

and

\[
\lambda - d \text{ with exponent } (d-2) \lambda^{d-1}, \text{i.e. equation (4) has the root } \lambda = d \text{ with multiplicity at least } (d-2) \lambda^{d-1}.
\]
\[ G'(\omega) = \frac{v k_B T}{N} \sum_{i=1}^{N} \frac{\omega / 2 \sigma \lambda_i}{1 + (\omega / 2 \sigma \lambda_i)^2}, \]  

(18)

where \( v \) denotes the number of polymer segments (beads) per unit volume.

We start by focusing on the averaged displacement \( \langle Y(t) \rangle \) equation (16), where we set \( \sigma = 1 \) and \( \varepsilon = 1 \). Figure 3 displays in double logarithmic scales the \( \langle Y(t) \rangle \) for the networks \( \Omega^d \) consisting of \( 4^d \) up to \( 4^{10} \) beads. As is known \(^{5,39}\), the \( \langle Y(t) \rangle \) in such GGS at very long times reaches the domain \( \langle Y(t) \rangle \sim \tilde{t}/(N\varepsilon) \) and at very short times obeying \( \langle Y(t) \rangle \sim \tilde{t}/\varepsilon^2 \). However, in intermediate regime the network’s beads move for several decades of time very slowly (logarithmic behavior), up to the times \( t \sim N \) related to the diffusive motion of the whole structure. This differs from the corresponding patterns for the dual Sierpinski gaskets (embedded into 3-dimensional space (there one gets \( \sigma > \mathcal{O}(4) \)) where \( \langle Y(t) \rangle \) reach the domain \( \langle Y(t) \rangle \sim \tilde{t}^{\varepsilon - 1} \) in double-logarithmic scales the slopes around 1. This result is \(^{57,38}\) which show a slow subdiffusive behavior \( \langle Y(t) \rangle \sim t^\xi \) where \( \xi \approx 0.23 \) for \( d = 4 \).

While the \( \langle Y(t) \rangle \) of \( \Omega^d \) do not scale in the intermediate domain, the mechanical relaxation functions show in the related frequency domain a scaling behavior, see the results for storage moduli \( G'(\omega) \) presented in Fig. 4. Here we plot them in dimensionless units by setting \( \sigma = 1 \) and \( \frac{v k_B T}{N} = 1 \). The networks are the same as for \( \langle Y(t) \rangle \) of Fig. 3. The \( G'(\omega) \) behaves commonly at very small and very high frequencies as \( \omega^2 \) and \( \omega^4 \), respectively. The in-between region of \( G'(\omega) \) (related to the intermediate time domain of \( \langle Y(t) \rangle \)) the curves give in double-logarithmic scales the slopes around 1. This result is bigger than that in the same region of the corresponding dual Sierpinski gaskets embedded into 3-dimensional space (there one has slopes near 0.77)\(^{39}\). For a better visualization, we plot in the inset of Fig. 4 the effective slopes \( \zeta = \frac{d(\log_{10} G')}{d(\log_{10} \omega)} \) for the same curves of Fig. 4. As expected, the limiting behaviors for very low and very high frequencies hold for slope 2 and slope 0. But in the intermediate frequency region, all of the four curves become wavy. Such a waviness reflects typically\(^{39-58}\) a very symmetric, hierarchical character of the structures. In case of real polymer systems, the inherent structural disorder smooths out such wavy patterns, while keeping the characteristic intermediate scaling\(^{39}\). Finally, the curves cross each other at the slope 1, keeping a short stable period and then falling into a value of 0.5.

**Fluorescence depolarization.** We are now embarking on the dynamics of energy transfer over a system of chromophores\(^8\). As a usual way, we assume that the nodes (beads) only transfer their energy with their nearest neighbors. Under these conditions the dipolar quasiresonant energy transfer among the chromophores obeys the following equation\(^6-8\):

\[
\frac{dP_i(t)}{dt} = \sum_{j \neq i} T_{ij} P_j(t) - \sum_{j \neq i} T_{ji} P_i(t),
\]

(19)

where \( P_i(t) \) represents the probability that node \( i \) is excited at time \( t \) and \( T_{ij} \) is the transfer rate from node \( j \) to node \( i \). Following the framework of Refs. 6–8, we separate the radiative decay (equal for all chromophores) from the transfer problem, which can be included by the multiplication of all the \( P_i(t) \) by \( \exp(-t/\tau_R) \), where \( 1/\tau_R \) corresponds to the radiative decay rate. Under the assumption that all microscopic rates are equal to each other, fixed on a value \( \tilde{k} \), equation (19) becomes

\[
\frac{dP_i(t)}{dt} = -\tilde{k} \sum_{j \neq i} L_{ij} P_j(t) - \left( \tilde{k} L_{ii} \right) P_i(t),
\]

(20)

where \( L_{ij} \) is the \( i \)th entry of Laplacian matrix \( L \). In equation (20) we used that for \( L \) the relation \( L_{ii} = -\sum_{j \neq i} L_{ij} \) holds.

The solution of equation (20) requires diagonalization of \( L \). The result for a given \( P_i(t) \) depends both on the eigenvalues and on the eigenvectors of \( L^d \). However, by averaging over all sites (a procedure fully justified when the dipolar orientations are independent of the beads’ position in the system), the probability of finding the excitation at time \( t \) on the originally excited chromophore depends only on the eigenvalues of \( L \) and is given by\(^8\):

\[
\langle P(t) \rangle = \frac{1}{N_g} \sum_{i=1}^{N_g} \exp\left( -\tilde{k} \lambda_i^2 t \right).
\]

(21)

Measuring the time in units of \( 1/\tilde{k} \), we can obtain the \( \langle P(t) \rangle \) with \( \tilde{k} = 1 \). In Fig. 5 we display in double logarithmic scales the average probability \( \langle P(t) \rangle \) that an initially excited chromophore of the network \( \Omega^d \) is still or again excited at time \( t \). As for the previous figures, we choose \( d = 4 \) and change the generation \( g \) from 7 to 10, which means that the number of beads varies from \( 4^7 \) to \( 4^{10} \). From Fig. 5 a waviness superimposed at early times can be observed immediately. Such waviness has been predicted in the regular hyperbranched...
fractals and it is related to high symmetry (regularity) of the network, i.e. the averaging due to possible disorder will smooth out the curves. Besides, in the intermediate time domain the decays show a power-law behavior, i.e. $\langle P(t) \rangle \sim t^{-\alpha}$. In Fig. 5 the $\alpha$ float around 0.98 for all four generations, a very high value among similar kinds of networks.

For the sake of comparison, in Fig. 6 we display the $\langle P(t) \rangle$ for dual Sierpinski gaskets embedded into 3-dimensional space for generations $g$ as those in Fig. 5. What is clear from the figure, the curves also scale in the intermediate time domain, but have a smaller scaling exponent $\alpha = 0.78$ compared to that of the networks introduced in this paper. Moreover, the four curves saturate to a constant value later than those of Fig. 5, while the plateau values $\langle P(\infty) \rangle$ are exactly the same for both figures and equal to $1/N_g^{\delta/2}$. This indicates that the equipartition of the energy over all beads is reached faster for the dual Sierpinski gaskets than for the dual Sierpinski networks.

Discussion
In summary, we have introduced a class of small-world networks constructed based on complete graphs. First, we have calculated the full Laplacian spectrum obtained from recursion formulae and proved its completeness. The corresponding analytic expressions allowed us to analyze the eigenvalues in detail and to calculate the related spectral dimension $\tilde{d}$. Using the eigenvalues, we have discussed the dynamics of such polymer networks in the GGSs framework, as well as the energy transfer through fluorescence depolarization. The ensuing spectral dimension $\tilde{d} = 2$ leaves its fingerprints in all quantities considered in the paper. In the intermediate time or frequency domain they follow the asymptotic relations $7,35,36$.

$$\langle Y(t) \rangle \sim \ln t,$$

$$G'(\omega) \sim G'(\omega) \sim \omega^{\delta/2} = \omega^1,$$

$$\langle P(t) \rangle \sim t^{-\tilde{d}/2} = t^{-1},$$

which were proven here by the numerical calculations. The networks introduced here are deterministic and highly structured, however, in case of a possible weak disorder leading to smoothing out of the curves the conclusions will still hold.

We believe that recent advances in the synthesis of fractal supramacromolecular polymers$^{37}$ will open new perspectives for the compounds constructed based on the symmetric small-world networks presented in the report. Finally, we remark that we expect to find more applications of the networks considered here; in particular, the analytic expressions for the Laplacian eigenvalues determined here will be of much help.

Methods
Characteristic polynomial for the Laplacian eigenvalues of $\Omega_g^d$. Following from the construction of $\Omega_g^d$, the adjacency matrix $A(\Omega_g^d)$, the degree matrix $D(\Omega_g^d)$, and the Laplacian matrix $L(\Omega_g^d)$ can be expressed as:

$$A(\Omega_g^d) = \begin{pmatrix} A(\Omega_{g-1}^d) & 1 & 1 & \cdots & 1 \\ I & 0 & 1 & \cdots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ I & I & I & \cdots & 0 \end{pmatrix}_{d \times d}$$

$$D(\Omega_g^d) = \text{diag}(D(\Omega_{g-1}^d) + (d-1)I, (d-1)I, \ldots, (d-1)I)_{d \times d}$$

and

$$L(\Omega_g^d) = D(\Omega_g^d) - A(\Omega_g^d)$$

$$L(\Omega_g^d) = \begin{pmatrix} L(\Omega_{g-1}^d) + (d-1)I & -I & -I & \cdots & -I \\ -I & (d-1)I & -I & \cdots & -I \\ -I & -I & (d-1)I & \cdots & -I \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -I & -I & -I & \cdots & (d-1)I \end{pmatrix}_{d \times d}$$

The characteristic polynomial of the $L(\Omega_g^d)$ is determined as:

$$P_g^L(\lambda) = \det(\lambda I - L(\Omega_g^d)).$$

The matrix $\lambda I - L(\Omega_g^d)$ can be rewritten as:

$$\lambda I - L(\Omega_g^d) = \text{diag}(\lambda - dI, L(\Omega_{g-1}^d), \lambda - dI, \ldots, \lambda - dI)_{d \times d}$$

$$+ \begin{pmatrix} I \\ \vdots \\ I \end{pmatrix} (1, \ldots, 1)_{1 \times d}.$$
The following form of the determinant can also be derived directly from those of $L_1$ and $L_2$, which will be separately treated as follows.

For the case of $\lambda = d$, equation $(\lambda J - L_1(\Omega_y^d))v = 0$ becomes

$$(\begin{array}{cccc}
L_{d-1} - I(\Omega_y^d) & L_{d-2} & \cdots & L_{d-1} \\
L_{d-2} & L_{d-3} & \cdots & L_{d-2} \\
\vdots & \vdots & \ddots & \vdots \\
L_{d-1} & L_{d-2} & \cdots & L_{d-1}
\end{array})
\begin{array}{c}
v_1 \\
v_2 \\
\vdots \\
v_d
\end{array} = 0,$$

where $v_1, v_2, \ldots, v_d$ are components of $v$. Equation (34) leads to the following equations:

$$\begin{align*}
v_1 + v_2 + v_3 + \cdots + v_d &= L(\Omega_y^d)v_1, \\
v_1 + v_2 + v_3 + \cdots + v_d &= 0.
\end{align*}$$

Then we know that $v_1$ is the eigenvector corresponding to the eigenvalue 0 in $L(\Omega_y^d)$, that is, $v_1 = (1, 1, \ldots, 1)^T$. Let $v_i = (v_{i1}, v_{i2}, \ldots, v_{id})^T$, then, Eq. (35) is equivalent to the following equations:

$$\sum_{i=2}^d v_{ij} = -v_{1j}, (j = 1, 2, \ldots, d^{-1}).$$

The set of all solutions to any of the above equations consists of vectors of the following form

$$(\begin{array}{c}
v_{1j} \\
v_{2j} \\
v_{3j} \\
\vdots \\
v_{dj}
\end{array}) = (\begin{array}{c}
-v_{1j} \\
0 \\
+k_{1j} \\
\vdots \\
0
\end{array}),$$

where $k_{1j}, k_{2j}, \ldots, k_{dj}$ are arbitrary real numbers. In Eq. (37), the solutions for all the vectors $v_i (2 \leq i \leq d)$ can be rewritten as

$$(\begin{array}{c}
v_{1j} \\
v_{2j} \\
v_{3j} \\
\vdots \\
v_{dj}
\end{array}) = (\begin{array}{c}
-v_{1j} \\
0 \\
+k_{1j} \\
\vdots \\
0
\end{array}),$$

where $k_{1j}, k_{2j}, \ldots, k_{dj}$ are arbitrary real numbers. Using Eq. (38), we can obtain the eigenvector $v$ associated with the eigenvalue $d$. Furthermore, we can easily check that the dimension of the eigenspace of matrix $L(\Omega_y^d)$ corresponding to eigenvalue $d$ is $(d - 2)d^{-1}$. We proceed to address the case of $\lambda \neq \lambda_y$. For this case, equation $(\lambda J - L(\Omega_y^d))v = 0$ can be rewritten as

$$(\begin{array}{cccc}
\lambda - d & L_{d-1} & \cdots & L_{d-1} \\
L_{d-2} & \lambda - d & \cdots & L_{d-2} \\
\vdots & \vdots & \ddots & \vdots \\
L_{d-1} & L_{d-2} & \cdots & \lambda - d
\end{array})
\begin{array}{c}
v_1 \\
v_2 \\
\vdots \\
v_d
\end{array} = 0,

where $v_1, v_2, \ldots, v_d$ are components of $v$. Eq (39) leads to the following equations:

$$\begin{align*}
v_1 + v_2 + v_3 + \cdots + v_d &= 0, \\
v_1 + v_2 + v_3 + \cdots + v_d &= 1,
\end{align*}$$

Resolving Eq. (40) yields

$$\begin{align*}
\begin{pmatrix}
\lambda - \lambda_x \\
\lambda - \lambda_y
\end{pmatrix}
\begin{pmatrix}
1 \\
0
\end{pmatrix} = 0,
\end{align*}$$

As demonstrated in the first subsection of Methods, we have that $\lambda$ is an eigenvalue of $L(\Omega_y^d)$, then $v(y) = \frac{\lambda - d}{\lambda - 1}$ is an eigenvalue of $L(\Omega_y^d)$. When $d \leq d^*-1$, we have $\lambda \leq \frac{\lambda - d}{\lambda - 1} = \lambda_y$, while in the situation $d^{*-1} < d \leq 2d^*-1$, $\lambda \geq \frac{\lambda - d}{\lambda - 1} = \lambda_x$. From Eq. (41), vector $v_1$ is the eigenvector of $L(\Omega_y^d)$ corresponding to the eigenvalue $\lambda_x$. Applying the $v_1$ into Eq. (41), we will get all of the $v_i (2 \leq i \leq d)$ and finally the eigenvector of $L(\Omega_y^d)$ corresponding to $\lambda_y$. In this way, we have completely determined all eigenvalues and their corresponding eigenvectors of $L(\Omega_y^d)$.
