RESUME
Background. The study of the parameters of optical coherence tomography with angiography (OCTA) broadens the understanding of the state of hemodynamics for the early detection of vascular disorders of the organ of vision in atherosclerosis (AS).

Purpose. To study the parameters of OCTA with changes in the organ of vision against the background of AS.

Material and methods. 26 patients (41 eyes) with changes in the organ of vision in AS. The age contingent of patients ranged from 32 to 78 years, the average age was 47.5 ± 2.0 g, of which 10 were women, 16 men. Depending on the damage to target organs, all patients were conditionally divided into 2 groups: group I (19 eyes) included patients without damage, and group II (22 eyes) consisted of patients with target organs damage.

Results. The registration of OCTA in patients of group I, a decrease in the density of capillaries of the superficial vascular network was 15% and amounted to 45.21 ± 2.62% (p <0.05), of the deep vascular plexus by 19%, which amounted to 45.89 ± 2.71% (p <0.05). In the macular region, the area of the hypoperfused retina was 1.07 ± 0.14 mm² (p <0.05). In the region of the optic nerve disc, areas of hypoperfusion were noted in the superficial layers in 7 eyes and in the deep layers in 4 eyes. Analysis of OCTA in patients of group II revealed a sharp decrease (by 48%) in the density of capillaries in both the superficial and deep vascular plexuses of the retina, which amounted to 33.91 ± 3.01% (p <0.05); 33.65 ± 2.89% (p <0.05), respectively. In the macular region, the area of the non-perfused retina was 2.19 ± 0.21 mm² (p <0.05). In the area of the optic nerve disc, areas of nonperfusion were noted both in the surface layers and in the deep layers in 4 eyes.

Conclusion. The use of OCTA allows to detect changes in hemoperfusion in all layers of the retina and optic nerve in the early stages of AS development, which will allow early diagnosis and monitoring of the disease.

KEY WORDS: optical coherence tomography with angiography, ischemic diseases, organ of vision, atherosclerosis, hemoperfusion, vascular plexuses, retina and optic nerve.

INTRODUCTION
In recent years, atherosclerosis (AS) is considered to be a pathological process that most often affects the elderly and senile, but there is a tendency to “rejuvenate” the disease [1, 2].

Disruption of blood patency along the aperture and venous vascular bed leads to ischemic changes not only in the posterior, but also in the anterior segment of the eyeball with the development of secondary dystrophies [4, 5, 6]. At the same time, ophthalmic manifestations may be the only predictors of the development of acute circulatory disorders of the brain and heart. Therefore, early detection of disturbances in the hemocirculation of acute respiratory infections is an important task that will prevent the development of formidable diseases that threaten the patient's life.

In ophthalmology, methods for evaluating the hemodynamics of the eyeball have been widely used in recent years. One of the highly informative, easily accessible and non-invasive methods is optical coherence tomography with angiography mode (OCT-angiography (OCTA)). This method is characterized by calculating changes in the amplitude...
of optical rays reflected from tissues. The method is based on measuring the degree of amplitude decorrelation at a certain point in the optical B-scan when performing several consecutive b-scans (split-spectrum amplitude-decorrelation angiography-SSADA), which is the result of changes in the characteristics of scattering and absorption of the beam at a particular scanning point over time.

The study of OCTA parameters expands the understanding of the state of the vascular network of the retina, optic nerve and choroid, which contributes to a detailed study of hemodynamics for early detection of vascular disorders of the organ of vision at AS without the introduction of dye [1-3].

**Purpose of research.** To study the parameters of optical coherence tomography with angiography for changes in the visual organ against the background of atherosclerosis.

**MATERIAL AND METHODS**

A total of 26 patients (41 eyes) with changes in organ of vision at AS were examined. The age group of patients ranged from 32 to 78 years, while the average age was 47.5±2.0 g, of which 10 were women and 16 were men. The criterion for inclusion of patients in this study, according to the recommendations of WHO experts, was: the presence of dyslipidemia (increased levels of total cholesterol, triglycerides, lipoproteins), increased body mass index, smoking index, the ratio of the waist and hip circumferences, as well as AS (echographically, angiographically or coronographically proven) damage to the vessels of the target organs. The exclusion criteria from this study were: the presence of diabetes mellitus, diseases of the organ of vision, acute disturbance of cerebral circulation, malignant and autoimmune diseases.

The diagnosis, as well as damage to target organs in atherosclerosis, was established by cardiologists, neurologists and angiosurgeons.

For scientific research, the approval of the Ethical Commission for Medical Research of the Ethical and Pharmaceutical Committee of the Republic of Uzbekistan was received in accordance with the Helsinki Declaration of the World Medical Association. Also, for inclusion in the research work, voluntary informed consent of the patients was obtained.

Depending on the damage to the target organs (brain and heart), all patients were conditionally divided into 2 groups: the first group (19 eyes) included patients without target organ damage, and the second group (22 eyes) consisted of patients with organ damage - targets.

All patients underwent a comprehensive examination, including a study of central visual acuity, kinetic and computer static perimetry, tonometry, gonioscopy, biomicroscopy, fundus ophthalmoscopy, ultrasound dopplerography of the vessels of the eye and brachiocephalic trunk.

For multimodal assessment of the (morphological and hemodynamic) parameters of optic nerve head and the retina, all patients were examined on the optic nerve head region (ONH protocol) and the macular region (RNFL, GCC) on an optical coherent tomograph with the TOPCON Triton plus angiography function (Ver. 10.13) (Swept Source OCT).

Scanning was carried out at a speed of 100,000 scans per 1 second. This mode allows you to receive OKTA-grams in the following sizes: 3 × 3, 4.5 × 4.5, 6 × 6 and 7.5 × 7.5 mm with a resolution of 304 × 304 pixels. The retina scans were automatically segmented into “superficial”, “deep” layers of the inner retina; outer retina and choriocapillary layer.

A statistical analysis of the data was carried out using the software package Statistica 6.0. The mean value (M), standard deviation (s) were determined. To compare the variational series, the Mann – Whitney, Wilcoxon, and Z-criteria were used. The critical significance level was 5% (p <0.05).

**RESULTS AND DISCUSSION**

In the study of visual acuity, the indicators were within normal values and amounted to a maximum correction of 0.87 ± 0.18 (p <0.05) with an average correction, intraocular pressure within 17.41 ± 0.21 mm Hg (p <0.05). When examining the visual fields in 6 eyes, relative scotomas were determined, in 5 eyes a concentric narrowing, 8 eyes without pathological changes in the visual fields.

When recording computer perimetric data, a decrease in retinal photosensitivity was noted - MD - 2.51 ± 0.11 dB, PSD 3.59 ± 0.09 dB (p <0.05), relative scotomas were observed, an increase in the blind spot area while maintaining high acuity view.

A study on an optical coherence tomograph revealed a thickening of the layer of retinal nerve fibers (RNFL) of the upper and lower segments in 11 eyes, a thinning of the neuroretinal girdle (NRG) in 7 eyes, and a thinning of the para- and perifocal region in 8 eyes.

When registering OCTA in patients of the first group, there was a decrease in the density of capillaries of the superficial layer - the superficial vascular network by 15% and amounted to 45.21 ± 2.62% (p <0.05), of the deep layer - of the deep vascular network by 19%, which 45.89 ± 2.71% (p <0.05). In the macular region, the area of the hypoperfused retina was 1.07 ± 0.14 mm² (p <0.05).

In area optic nerve head, hypoperfusion sites were noted in the superficial layers on 7 eyes, in the deep layers on 4 eyes (Fig. 1-see Appendix).

During ophthalmodopplerography, hemodynamically insignificant asymmetry of blood circulation was registered spasm of the ophthalmic artery (OA), Central retinal artery (CRA) and posterior short ciliary arteries (PSCA), the resistivity...
index (RI) was within normal values and amounted to (OA, CRA, PSCA) – 0.69; 0.65; 0.60 (respectively) (p<0.05). The condition of collateral blood circulation in the superficial temporal artery (STA) was within normal values.

In the study of patients of the second group, indicators of visual acuity with maximum correction were within 0.07 ± 0.002 (p <0.05), intraocular pressure within 21.31 ± 0.09 mm Hg (p <0.05). With kinetic perimetry, absolute scotomas were determined on 7 eyes, eccentric narrowing on 7 eyes, and sectoral loss of visual fields on 8 eyes. The category of these patients showed a steady decrease in both central, peripheral and peripheral vision.

A study of the photosensitivity of the retina on computer perimetry recorded its decrease and amounted to - MD -13.11 ± 0.42 dB, PSD 7.81 ± 0.21 dB (p <0.05). Also, a decrease in the photosensitivity of the paired eye was observed in patients of this group while maintaining high visual acuity.

The next category of patients showed changes in the parameters of OCT in the form of an increase in the area of the NRG (14 eyes) and a thickening of the RNFL in the peripapillary zone. The presence of areas of high neuroretinal edema (12 eyes) was also recorded here. High cystic edema of the macular area was registered in 9 eyes, which were subsequently recommended anti-VEGF therapy.

The analysis of OCTA in patients of the second group with damage to target organs revealed a sharp decrease (by 48%) in the density of capillaries in both the superficial –S and deep –D vascular plexuses of the retina, which amounted to 33.91 ± 3.01% (p <0.05); 33.65 ± 2.89% (p <0.05), respectively. In the macular region, the area of the non-perfused retina was 2.19 ± 0.21 mm2 (p <0.05) (Fig. 2 see Appendix). In the area of the optic disc, areas of nonperfusion were noted both in the surface layers and in the deep layers in 4 eyes.

During dopplerography, hemodynamically significant asymmetry of blood circulation parameters in the main vessels of the eye and extranial parts of brachiocephalic material was registered. Thus, the stability index of eye vessels was increased and amounted to RI (OA, CRA, PSCA) - 0.74; 0.71; 0.69 (respectively) (p<0.05). When studying the consistency of collateral blood circulation in STA, a decrease in hemodynamic parameters was registered (39.14 2, 2.19 cm/S (p<0.05)) and an increase in the stability index (RI STA-0.72), which predicted an unfavorable course of the ischemic process [5].

In addition, in patients with target organ damage, a concomitant pathology was revealed in the form of grade I - II arterial hypertension (9 patients), chronic brain ischemia (7 patients), coronary heart disease (5 patients), which was not observed in patients without organ damage - targets.

To date, there are few works in the literature on the use of OCTA in vascular pathology of organ of vision [2, 9, 12, 13]. Thus, the authors used the OCTA method for occlusion of the retinal veins, where they revealed the least perfusion in the ischemic type of occlusion of the retinal veins. There was a difference in perfusion indices with ischemic and non-ischemic types only with a scan area of 3 × 3 mm. The authors, in addition to hypoperfusion in both the superficial and deep vascular network, observed the presence of microaneurysms and telangiectasias in the examined patients [12]. This proves that OCTA allows detecting perfusion disorders in all vascular layers of the central zone of the retina, as well as microvascular abnormalities in patients with retinal vein occlusion.

Gendelman I. and co-authors found an increase in blood flow deficit in choriocapillaries with its increase closer to the macular area in patients with diabetic retinopathy [13].

The authors of [16] note the high sensitivity (89.2%) and specificity (93.3%) of OCTA in detecting types of neovascularization of age-related macular degeneration, where the newly formed vessels are located under the pigment epithelium with a latent form of chronic neovascularization and classical with localization of the neovascular complex above pigmented epithelium.

CONCLUSION

This study revealed hemoperfusion disorders in all layers of the retina and optic nerve head in the early stages of the development of the AS process, when the target organs were not yet involved. This condition demonstrates the possibility of using the OCTA method for early identification of atherosclerosis in the early stages of the disease, which will prevent the disability of the population and prevent deaths.

With the generalization of atherosclerosis and damage to target organs, the use of OCTA allows monitoring of the ischemic process, which contributes to a more adequate management of patients with hemodynamic impairment of organ of vision in AS.
