A POSTERIORI ERROR ESTIMATES FOR NON-STATIONARY NON-LINEAR CONVECTION-DIFFUSION EQUATIONS

R. VERFÜRTH

Abstract. Motivated by stochastic convection-diffusion problems we derive a posteriori error estimates for non-stationary non-linear convection-diffusion equations acting as a deterministic paradigm. The problem considered here neither fits into the standard linear framework due to its non-linearity nor into the standard non-linear framework due to the lacking differentiability of the non-linearity. Particular attention is paid to the interplay of the various parameters controlling the relative sizes of diffusion, convection, reaction, and non-linearity (noise).

1. Introduction

Recently stochastic convection-diffusion problems have attracted considerable interest \cite{2, 6, 7, 8, 17, 19, 26}. To obtain efficient numerical discretizations adaptivity is mandatory. Yet, for these problems, adaptivity in general and a posteriori error estimates in particular are still in their infancy. As a first step to close this gap we consider in this article deterministic non-stationary convection-diffusion equations with a non-linearity of the form $\nu \varphi(u)g$ modelling the noise (cf. equation (2.1) below). They neither fit into the framework of \cite[§3]{21} and \cite[§6.2]{25} due to the non-linearity, nor into the framework of \cite{1, 12, 24, 23}, and \cite[§6.6]{25} due to the lacking differentiability of the non-linearity or its lacking strong monotonicity. Therefore, in what follows, we will carefully adapt the arguments of \cite[§3]{21} and \cite[§6.2]{25} to catch the interplay of the various parameters controlling the relative size of diffusion, convection, reaction, and non-linearity.

The article is organized as follows. In Section 2 we present the differential equation and its variational formulation. Section 3 gives the discretization which is a stabilized $\theta$-scheme with a possibly explicit treatment of the non-linearity. In Section 4 we then derive the a posteriori error estimates (cf. Theorem 4.14).

2. Variational Problem

As a deterministic paradigm for stochastic convection-diffusion problems, we consider the following non-stationary non-linear convection-diffusion equations:

\begin{equation}
\begin{aligned}
&\partial_t u - \varepsilon \Delta u + a \cdot \nabla u + bu = \nu \varphi(u)g & \text{in } \Omega \times (0, T], \\
&u = 0 & \text{on } \Gamma \times (0, T], \\
&u(\cdot, 0) = u_0 & \text{in } \Omega.
\end{aligned}
\end{equation}

(2.1)

Here, $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, is a bounded polyhedral domain with Lipschitz boundary $\Gamma$. The final time $T$ is arbitrary, but kept fixed in what follows. We assume that the data satisfy the following conditions (compare \cite[§3]{21} and \cite[§6.2]{25}):

(A1) $\varepsilon > 0$, $\nu \geq 0$,
(A2) \( g \in L^\infty(\Omega \times (0, T]), a \in C(0, T; W^{1, \infty}(\Omega)^d), b \in L^\infty(\Omega \times (0, T]), u_0 \in L^2(\Omega), \)

(A3) there are two constants \( \beta \geq 0 \) and \( c_b \geq 0 \), which do not depend on \( \epsilon \), such that \(- \frac{1}{\epsilon} \text{div} a + b \geq \beta \) in \( \Omega \times (0, T] \) and \( \| b \|_{L^\infty(\Omega \times (0, T])} \leq c_b \beta \),

(A4) the function \( \varphi \), modelling the noise, is Lipschitz continuous, i.e.

\[ |\varphi(s_1) - \varphi(s_2)| \leq L |s_1 - s_2| \] for all \( s_1, s_2 \in \mathbb{R} \).

Examples of functions satisfying assumption (A4) with \( L = 1 \) are \( \varphi(s) = 1 + |s| \) and \( \varphi(s) = \sqrt{1 + s^2} \).

We will be particularly interested in the convection-dominated regime \( \epsilon \ll 1 \). At the expense of more technical arguments and additional data oscillations, the second assumption can be replaced by slightly weaker conditions concerning the temporal regularity. The third assumption allows us to simultaneously handle the case of a non-vanishing reaction term and the one of absent reaction. If \( b \neq 0 \) we may assume without loss of generality that \( c_b \geq 1 \); if \( b = 0 \) we set \( \beta = 0 \) and \( c_b = 1 \).

We denote by \( L^p(\Omega) \) and \( W^{k,p}(\Omega) \), \( 1 \leq p \leq \infty, k \geq 1 \), the standard Lebesgue and Sobolev spaces equipped with their standard norms \( \| \cdot \|_{L^p(\Omega)} \) and \( \| \cdot \|_{W^{k,p}(\Omega)} \) respectively, by \( H^1_0(\Omega) \) the space of all functions in \( W^{1,2}(\Omega) \) with vanishing trace, and by \( H^{-1}(\Omega) \) the dual space of \( H^1_0(\Omega) \). The norms of \( H^1_0(\Omega) \) and \( H^{-1}(\Omega) \) depend on \( \epsilon \) and \( \beta \) and are specified in (4.1) and (4.2) below. Further, we define a bilinear form \( B : H^1_0(\Omega) \times H^1_0(\Omega) \to \mathbb{R} \) and a non-linear map \( N : H^1_0(\Omega) \to H^{-1}(\Omega) \) by setting for all \( u, v \in H^1_0(\Omega) \)

\[
B(u, v) = \int_\Omega (\epsilon \nabla u \cdot \nabla v + a \cdot \nabla u v + b u v), \\
\langle N(u), v \rangle = \int_\Omega \nu \varphi(u) g v.
\] (2.2)

Remind that \( B \) and \( N \) depend on time \( t \) due to the functions \( a \), \( b \), and \( g \).

The variational formulation of problem (2.1) then is to find a function \( u \) in \( L^2(0, T; H^1_0(\Omega)) \) with its weak temporal derivative \( \partial_t u \) in \( L^2(0, T; H^{-1}(\Omega)) \) such that \( u(\cdot, 0) = u_0 \) almost everywhere and

\[
(\partial_t u, v) + B(u, v) = \langle N(u), v \rangle 
\] (2.3)

for all \( v \in H^1_0(\Omega) \) and almost all \( t \in (0, T) \).

In what follows we assume that problem (2.3) admits at least one solution.

3. DISCRETE PROBLEM

For the space-time discretization of problem (2.1), we consider partitions \( \mathcal{I} = \{[t_{n-1}, t_n] : 1 \leq n \leq N_T \} \) of the time-interval \( [0, T] \) into sub-intervals satisfying \( 0 = t_0 < \ldots < t_{N_T} = T \). For every \( n \) with \( 1 \leq n \leq N_T \), we denote by \( I_n = [t_{n-1}, t_n] \) the \( n \)-th sub-interval and by \( \tau_n = t_n - t_{n-1} \) its length. With every intermediate time \( t_n \), \( 0 \leq n \leq N_T \), we associate a partition \( \mathcal{T}_n \) of \( \Omega \) and a corresponding finite element space \( V(T_n) \). The partitions \( \mathcal{I} \) and \( \mathcal{T}_n \) and the spaces \( V(T_n) \) must satisfy the following assumptions (compare [24 §3] and [24 §6.2]):

- The closure of \( \Omega \) is the union of all elements in \( \mathcal{T}_n \).
- Every element has at least one vertex in \( \Omega \).
- Every element in \( \mathcal{T}_n \) is either a simplex or a parallelepiped, i.e. it is the image of the \( d \)-dimensional reference simplex \( \tilde{K}_d = \{ x \in \mathbb{R}^d : x_1 \geq 0, \ldots, x_d \geq 0, x_1 + \ldots + x_d \leq 1 \} \) or of the \( d \)-dimensional reference cube \( \tilde{K}_d = [0, 1]^d \) under an affine mapping (affine-equivalence).
- Any two elements in \( \mathcal{T}_n \) are either disjoint or share a complete lower dimensional face of their boundaries (admissibility).
• Denoting by $h_K$ the diameter of any element $K$ and by $\rho_K$ the diameter of the largest ball inscribed into $K$, the shape parameter

$$C_T = \max_{1 \leq n \leq N_T} \max_{K \in T_n} \frac{h_K}{\rho_K}$$

is of moderate size independently of $\varepsilon$, $\beta$, and $\nu$ (shape-regularity).

• For every $n$ with $1 \leq n \leq N_T$ there is an affine-equivalent, admissible, and shape-regular partition $\widetilde{T_n}$ such that it is a refinement of both $T_n$ and $T_{n-1}$ and such that

$$C_{\widetilde{T}, T} = \max_{1 \leq n \leq N_T} \max_{K \in T_n} \max_{K' \in \mathcal{T}_n : K \subset K'} \frac{h_K}{h}$$

is of moderate size independently of $\varepsilon$, $\beta$, and $\nu$ (transition condition).

• Each $V(T_n)$ consists of continuous functions which are piecewise polynomials, the degrees being at least one and being bounded uniformly with respect to all partitions $T_n$ and $\mathcal{T}$ (degree condition).

The transition condition is due to the simultaneous presence of finite element functions defined on different grids. Usually the partition $T_n$ is obtained from $T_{n-1}$ by a combination of refinement and of coarsening. In this case the transition condition only restricts the coarsening: it should not be too abrupt nor too strong.

The lower bound on the polynomial degrees is needed for the construction of suitable quasi-interpolation operators. The upper bound ensures that the constants in inverse estimates are uniformly bounded.

Notice that we do not impose any shape-condition of the form $\max_n \tau_n \leq c \min_n \tau_n$.

For any parameter $\Theta \in [0, 1]$ we set for abbreviation

$$g^{n\Theta} = \Theta g(\cdot, t_n) + (1 - \Theta) g(\cdot, t_{n-1}),$$

$$a^{n\Theta} = \Theta a(\cdot, t_n) + (1 - \Theta) a(\cdot, t_{n-1}),$$

$$b^{n\Theta} = \Theta b(\cdot, t_n) + (1 - \Theta) b(\cdot, t_{n-1})$$

and

$$B^{n\Theta}(u, v) = \int_\Omega \{\varepsilon \nabla u \cdot \nabla v + a^{n\Theta} \cdot \nabla uv + b^{n\Theta} uv\},$$

$$\langle N^{n\Theta}(u), v \rangle = \int_\Omega \nu \varphi(u) g^{n\Theta} v.$$
A Posteriori Error Estimates

In what follows we assume that problem (3.2) admits at least one solution. To this end we proceed as in [21] and [25 §6.2]:

- We introduce the residual associated with the error and prove that a suitable norm of the error is bounded from below and above by a suitable dual norm of the residual.
We additively split the residual into three contributions called data residual, temporal residual, and spatial residual.

We separately bound the dual norms of the data, temporal, and spatial residuals.

In following this path, we must pay particular attention to the non-linearity. Its Lipschitz-continuity will be crucial.

4.1. Norms. We equip $H^1_0(\Omega)$ with the energy norm
\begin{equation}
\|v\| = \left\{ \epsilon \|\nabla v\|^2 + \beta \|v\|^2 \right\}^{\frac{1}{2}}
\end{equation}
and $H^{-1}(\Omega)$ by the corresponding dual norm
\begin{equation}
\|\ell\|_* = \sup_{v \in H^1_0(\Omega) \setminus \{0\}} \frac{\langle \ell, v \rangle}{\|v\|},
\end{equation}
where $\|\cdot\|$ is the standard $L^2$-norm on any measurable subset $\omega$ of $\Omega$ and $\|\cdot\| = \|\cdot\|_\omega$.

For abbreviation we set for $0 \leq t_- < t_+ \leq T$
\begin{equation}
X(t_-, t_+) = L^2(t_-, t_+; H^1_0(\Omega)) \cap L^\infty(t_-, t_+; L^2(\Omega)) \cap H^1(t_-, t_+; H^{-1}(\Omega)),
\end{equation}
equip it with the norm
\begin{equation}
\|u\|_{X(t_-, t_+)} = \left\{ \sup_{t_- < t < t_+} \|u(\cdot, t)\|^2 + \int_{t_-}^{t_+} \|u(\cdot, t)\|^2 \right. \\
+ \int_{t_-}^{t_+} \|\partial_t u(\cdot, t) + a \cdot \nabla u(\cdot, t)\|^2 \left. \right\}^{\frac{1}{2}},
\end{equation}
and set
\begin{equation}
X = X(0, T), \quad \|\cdot\|_X = \|\cdot\|_{X(0, T)}.
\end{equation}
Recall that for $0 \leq t_- < t_+ \leq T$ and $\ell : (t_-, t_+) \to H^{-1}(\Omega)$
\begin{equation}
\|\ell\|_{L^2(t_- t_+; H^{-1}(\Omega))} = \left\{ \int_{t_-}^{t_+} \|\ell(t)\|^2 \right\}^{\frac{1}{2}}.
\end{equation}

Denote by
\begin{equation}
c_F = \sup_{v \in H^1_0(\Omega) \setminus \{0\}} \frac{\|v\|}{\|\nabla v\|}
\end{equation}
the best constant in Friedrich’s inequality. Note that $c_F \lesssim \text{diam}(\Omega)$. Setting
\begin{equation}
\lambda = \min \left\{ c_F \epsilon^{-\frac{1}{2}}, \beta^{-\frac{1}{2}} \right\}
\end{equation}
equations (4.1) and (4.3) imply for every $v \in H^1_0(\Omega)$
\begin{equation}
\|v\| \leq \lambda \|v\|.
\end{equation}

For abbreviation we finally set
\begin{equation}
\gamma(t) = \|g(\cdot, t)\|_{L^\infty(\Omega)}, \quad \gamma = \|g\|_{L^\infty(\Omega \times (0, T))}.
\end{equation}
4.2. Lipschitz-continuity of the non-linearity. The non-linearity $N$ is not differentiable, but Lipschitz-continuous.

**Lemma 4.1** (Lipschitz-continuity of $N$). For every $t \in (0, T)$ and $u_1, u_2, v \in H^1(\Omega)$ we have

\[
\langle N(u_1) - N(u_2), v \rangle \leq \nu L \gamma(t) \| u_1 - u_2 \| \| v \|
\]

and

\[
\| N(u_1) - N(u_2) \| \leq \nu L \gamma(t) \| u_1 - u_2 \| \leq \nu L \lambda^2 \gamma(t) \| u_1 - u_2 \|.
\]

**Proof.** For every $v \in H^1(\Omega)$ and $t \in (0, T)$ we have thanks to assumption (A4)

\[
\langle N(u_1) - N(u_2), v \rangle \leq \nu L \int_{\Omega} |g(\cdot, t)| \| u_1 - u_2 \| |v|.
\]

Together with Hölder’s inequality this proves the first inequality. The second and third one, follow from the first one and (4.4).

□

**Remark 4.2.** Using the continuous embedding of $H^1(\Omega)$ into $L^p(\Omega)$ with $p < \infty$ if $d = 2$ and $p = 6$ if $d = 3$, the terms $\nu L \gamma(t)$ and $\nu L \lambda^2 \gamma(t)$ in Lemma 4.1 can be replaced by $\min \{ \nu L \beta^{-1} \gamma(t), \nu L c_p \varepsilon^{-\frac{1}{2}} \| g(\cdot, t) \|_{L^p(\Omega)} \}$ and $\min \{ \nu L \beta^{-1} \gamma(t), \nu L c_p \varepsilon^{-\frac{1}{2}} \| g(\cdot, t) \|_{L^p(\Omega)} \}$, resp. where $q = \frac{2p}{p-2}$, $r = \frac{p}{p-2}$, and $c_p = \sup_{v \in \| v \|_{L^p(\Omega)}}$. 

4.3. Equivalence of residual and error. With the discrete solution $u_\tau$ we associate the residual $R(u_\tau) \in L^2(0, T; H^{-1})$ by setting for all $v \in H^1(\Omega)$

\[
\langle R(u_\tau), v \rangle = \langle N(u_\tau), v \rangle - \langle \partial_t u_\tau, v \rangle - B(u_\tau, v).
\]

Notice, that $B$ and $N$ are given by (2.2) and that $\partial_t u_\tau = \frac{1}{\tau_n} (u^n_{\tau_n} - u^{n-1}_{\tau_{n-1}})$ on $[t_{n-1}, t_n]$. With this notation, we have the following equivalence of error and residual.

**Lemma 4.3** (Equivalence of error and residual). For all $1 \leq n \leq N_T$ the $L^2(t_{n-1}, t_n; H^{-1}(\Omega))$-norm of the residual is bounded from above by the $X(t_{n-1}, t_n)$-norm of the error

\[
\| R(u_{\tau}) \|_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \leq \| u - u_\tau \|_{X(t_{n-1}, t_n)} \sqrt{2} c_b \left\{ 1 + \nu L \lambda \min \{ \lambda, \sqrt{T_n} \} \max_{t_{n-1} \leq t \leq t_n} \gamma(t) \right\}.
\]

Conversely, the $X(0, T)$-norm of the error is bounded from above by the $L^2(0, T; H^{-1}(\Omega))$-norm of the residual

\[
\| u - u_{\tau} \|_{X} \leq \left\{ \| u_0 - u^n_{\tau_n} \|^2 + \| R(u_{\tau}) \|^2_{L^2(0, T; H^{-1}(\Omega))} \right\}^{\frac{1}{2}}.
\]

\[
\left\{ 3 + \left[ 1 + 3 \max \{ c_b^2, \nu L^2 \lambda^2 \gamma \min \{ T, \lambda^2 \} \} \right] e^{2 \nu L \gamma T} \right\}^{\frac{1}{2}}.
\]

If in addition $\kappa = 2\nu L \min \{ T, \lambda^2 \} \gamma < 1$, the upper bound for the norm of the error can be improved to

\[
\| u - u_{\tau} \|_{X} \leq \left\{ \| u_0 - u^n_{\tau_n} \|^2 + \| R(u_{\tau}) \|^2_{L^2(0, T; H^{-1}(\Omega))} \right\}^{\frac{1}{2}}.
\]

\[
\left\{ 3 + \left[ 1 + 3 \max \{ c_b^2, \frac{1}{2} \nu L^2 \gamma \} \right] \frac{1}{1 - \kappa} \right\}^{\frac{1}{2}}.
\]
If $|\kappa| < 1$ and thus together with Lemma 4.1 this implies the left-hand side and obtain the variational formulation (2.3) and the definition of the residual. Proof. The variational formulation (2.3) and the definition of the residual yield
\[
\langle \partial_t (u - u_T), v \rangle + B(u - u_T, v) = \langle N(u) - N(u_T), v \rangle + \langle R(u_T), v \rangle \quad (4.5)
\]
for all $v \in H^1_0(\Omega)$ and almost all $t \in (0, T)$. Therefore, Proposition 6.14] and the assumption $c_b \geq 1$ imply for all $1 \leq n \leq N_T$
\[
\|R(u_T)\|_{L^2(t-n, t_n, H^{-1}(\Omega))} \leq \sqrt{2} c_b \left\{ \|u - u_T\|_{X(t-n, t_n)} + \|N(u) - N(u_T)\|_{L^2(t-n, t_n, H^{-1}(\Omega))} \right\}.
\]
Together with Lemma 4.1 this implies the upper bound for the dual norm of the residual. To prove the upper bounds for the error, we go back to the proof of Proposition 6.14] and first observe that
\[
\langle \partial_t (u - u_T), a \cdot \nabla (u - u_T) \rangle = \int_\Omega [\nabla (u_T - u) \cdot \nabla v + b(u_T - u)v] + \langle N(u) - N(u_T), v \rangle + \langle R(u_T), v \rangle,
\]
Together with Lemma 4.1 this implies
\[
\|\partial_t (u - u_T) + a \cdot \nabla (u - u_T)\|_{n} \leq \|R(u_T)\|_{n} + c_b \|u - u_T\| + \nu L \gamma(t) \|u - u_T\|
\]
and
\[
\int_0^T \|\partial_t (u - u_T) + a \cdot \nabla (u - u_T)\|^2_n \leq 3 \left\{ \int_0^T \|R(u_T)\|^2_n + c_b^2 \int_0^T \|u - u_T\|^2 + \nu^2 L^2 \lambda^2 \gamma \min \left\{ T \sup_{0 < t < T} \|u - u_T\|^2, \lambda^2 \int_0^T \|u - u_T\|^2 \right\} \right\}.
\]
In order to bound $\sup_{0 < t < T} \|u - u_T\|^2$ and $\int_0^T \|u - u_T\|^2$, we now use a standard parabolic energy argument and insert $u - u_T$ as test-function $v$ in (4.5). Thanks to the coercivity of the bilinear form $B$ and Lemma 4.1 this yields
\[
\frac{1}{2} \frac{d}{dt} \|u - u_T\|^2 + \|u - u_T\|^2 \leq \frac{1}{2} \frac{d}{dt} \|u - u_T\|^2 + B(u - u_T, u - u_T)
\]
\[
= \langle N(u) - N(u_T), u - u_T \rangle + \langle R(u_T), u - u_T \rangle
\]
\[
\leq \nu L \gamma(t) \|u - u_T\|^2 + \|R(u_T)\|_n \|u - u_T\|
\]
\[
\leq \nu L \gamma(t) \|u - u_T\|^2 + \frac{1}{2} \|R(u_T)\|^2_n + \frac{1}{2} \|u - u_T\|^2
\]
and thus
\[
\|(u - u_T)(\cdot, t)\|^2 + \frac{d}{dt} \|u - u_T\|^2 \leq 2 \nu L \gamma \int_0^t \|u - u_T\|^2 + \int_0^t \|R(u_T)\|^2_n + \|u_0 - u_{T_0}\|^2.
\]
If $\kappa < 1$ we may absorb the first term on the right-hand side of this estimate by the left-hand side and obtain
\[
\sup_{0 < t < T} \|u - u_T\|^2 + \int_0^T \|u - u_T\|^2 \leq \frac{1}{1 - \kappa} \left\{ \|u_0 - u_{T_0}\|^2 + \|R(u_T)\|^2_{L^2(0, T; H^{-1}(\Omega))} \right\}.
\]
Otherwise, Gronwall’s Lemma yields
\[
\sup_{0 < t < T} \| u - u_T \|^2 + \int_0^T \| u - u_I \|^2 dt \leq e^{2\nu L^2 T} \left\{ \| u_0 - u_0^0 \|^2 + \| R(u_I) \|^2_{L^2(0,T;H^{-1}(\Omega))} \right\}.
\]
Combining these estimates with the bound for \( \int_0^T \| \partial_t (u - u_T) + \mathbf{a} \cdot \nabla (u - u_T) \|^2 dt \) establishes the upper bound for the error.

4.4. Decomposition of the residual. We additively split the residual
\[
R(u_I) = R_r(u_I) + R_h(u_I) + R_D(u_I)
\]
into a temporal residual, a spatial residual, and a data residual which, for all \( v \in H^1_0(\Omega) \), are defined by
\[
\langle R_r(u_I), v \rangle = \langle N^{n\theta}(u_I), v \rangle - \langle N^{n\theta}(U^{n\theta}), v \rangle + B^{n\theta}(U^{n\theta} - u_I, v),
\]
\[
\langle R_h(u_I), v \rangle = \langle N^{n\theta}(U^{n\theta}), v \rangle - \langle \partial_t u_I, v \rangle - B^{n\theta}(U^{n\theta}, v),
\]
\[
\langle R_D(u_I), v \rangle = (N(u_I), v) - \langle N^{n\theta}(u_I), v \rangle - B(u_I, v) + B^{n\theta}(u_I, v).
\]
In addition, we additively split the temporal residual
\[
R_r(u_I) = R_{r,lin}(u_I) + R_{r,nonlin}(u_I)
\]
into a linear and a non-linear part which, for all \( v \in H^1_0(\Omega) \), are defined by
\[
\langle R_{r,lin}(u_I), v \rangle = B^{n\theta}(U^{n\theta} - u_I, v),
\]
\[
\langle R_{r,nonlin}(u_I), v \rangle = (N^{n\theta}(u_I), v) - \langle N^{n\theta}(U^{n\theta}), v \rangle.
\]
In the following subsections we will estimate the three residuals separately. The following Lemma shows that this is permissible. Lemma 4.12 below in addition shows that the temporal residual is dominated by its linear part if \( \nu L^2 \gamma \) is sufficiently small.

**Lemma 4.4** (Decomposition of the residual). For every \( n \in \{1, \ldots, N_I\} \) we have
\[
\| R_r(u_I) + R_h(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \leq \| R_{r,lin}(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} + \| R_{r,nonlin}(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} + \| R_h(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))}
\]
and
\[
\frac{2}{25} \left\{ \| R_{r,lin}(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} + \| R_h(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \right\} ^{\frac{1}{2}}
\]
\[
\leq \| R_r(u_I) + R_h(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} + \| R_{r,nonlin}(u_I) \|^2_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))}.
\]
**Proof.** Since \( \sqrt{\frac{2}{25}} \left( 1 - \frac{\sqrt{2}}{25} \right) > \frac{2}{25} \) and \( R_{r,lin} \) is affine in \( U^{n\theta} - u_I \) and thus proportional to \( (t_{n-1} - t_n) - \theta \), the estimates follow from the triangle inequality and [25, Lemma 6.16].

4.5. Bounding the data residual. Hölder’s inequality and (4.4) yield the following upper bound for the data residual.
Lemma 4.5 (Upper bound for the data residual). For every \( n \in \{1, \ldots, N_T\} \) we have
\[
\| R_D(u_T) \|_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \leq \nu L \left\{ \left\| g - g^{n0} \right\|_{L^2(t_{n-1}, t_n; L^2(\Omega))} + \left( \int_{t_{n-1}}^{t_n} \| u_T \|^2 \right)^{\frac{1}{2}} \right\} + \epsilon^{-\frac{1}{2}} \left\| a - a^{n0} \right\|_{L^\infty(t_{n-1}, t_n; L^\infty(\Omega))} \left( \int_{t_{n-1}}^{t_n} \| u_T \|^2 \right)^{\frac{1}{2}} + \lambda^2 \left\| b - b^{n0} \right\|_{L^\infty(t_{n-1}, t_n; L^\infty(\Omega))} \left( \int_{t_{n-1}}^{t_n} \| u_T \|^2 \right)^{\frac{1}{2}}.
\]

Remark 4.6. Since \( u_T = \frac{t - t_{n-1}}{\tau_n} u^n_T + \frac{t_{n-1}}{\tau_n} u_{n-1}^{n-1} \) for \( t_{n-1} \leq t \leq t_n \), the convexity of \( \| \cdot \|^2 \) and Simpson’s rule yield
\[
\int_{t_{n-1}}^{t_n} \| u_T \|^2 \leq \frac{\tau_n}{2} \left( \| u^n_T \|^2 + \| u_{n-1}^{n-1} \|^2 \right).
\]

4.6. Bounding the temporal residual. We first bound the linear part of the temporal residual. For every time-interval \([t_{n-1}, t_n]\) we have
\[
R_{\tau, \text{lin}}(u_T) = (\theta - \frac{t_t - t_{n-1}}{\tau_n}) r^n
\]
where \( r^n \in H^{-1}(\Omega) \) is defined by
\[
\langle r^n, v \rangle = B^{n0} (u^n_T - u_{n-1}^{n-1}, v)
\]
for \( v \in H^1_0(\Omega) \). The assumption \( c_0 \geq 1 \) and [25] Lemma 6.17 therefore yield the following upper and lower bounds for the linear part of the temporal residual.

Lemma 4.7 (Bounds for the linear part of the temporal residual). For every \( n \in \{1, \ldots, N_T\} \), the linear part of the temporal residual can be bounded from above and from below by
\[
\frac{\sqrt{\tau_n}}{\sqrt{2} (2 + c_b)} \left\{ \left\| u^n_T - u_{n-1}^{n-1} \right\| + \left\| a^{n0} \cdot \nabla (u^n_T - u_{n-1}^{n-1}) \right\| \right\} \leq \left\| R_{\tau, \text{lin}}(u_T) \right\|_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \leq \frac{\sqrt{\tau_n}}{\sqrt{3} c_b} \left\{ \left\| u^n_T - u_{n-1}^{n-1} \right\| + \left\| a^{n0} \cdot \nabla (u^n_T - u_{n-1}^{n-1}) \right\| \right\}.
\]
The term \( \left\| a^{n0} \cdot \nabla (u^n_T - u_{n-1}^{n-1}) \right\| \) is not suited for a posteriori error estimates since it involves the dual norm \( \| \cdot \|_* \). The next two Lemmas bound this term for the case of dominant diffusion, i.e. \( \epsilon \geq 1 \), and of dominant convection, i.e. \( \epsilon \ll 1 \), respectively. The first one follows from Hölder’s inequality and [41,3], the second one from [25] Lemma 6.18.

Lemma 4.8 (Bounding the convective derivative for dominant diffusion). For every \( n \in \{1, \ldots, N_T\} \) we have
\[
\left\| a^{n0} \cdot \nabla (u^n_T - u_{n-1}^{n-1}) \right\| \leq \epsilon^{-\frac{1}{2}} \lambda \left\| a^{n0} \right\|_{L^\infty(\Omega)} \left\| u^n_T - u_{n-1}^{n-1} \right\|.
\]
Lemma 4.9 (Bounding the convective derivative for dominant convection). For every \( n \in \{1, \ldots, N_T\} \) denote by \( S_0^{1,0}(\overline{T}_n) \) the space of continuous, piecewise affine functions vanishing on \( \Gamma \) corresponding to the partition \( \overline{T}_n \) and by \( \tilde{u}_T^n \in S_0^{1,0}(\overline{T}_n) \) the unique solution of the discrete reaction-diffusion problem

\[
\varepsilon \int_{\Omega} \nabla \tilde{u}_T^n \cdot \nabla v_T^n + \beta \int_{\Omega} \tilde{u}_T^n v_T^n = \int_{\Omega} a^{\alpha \theta} \cdot \nabla(\tilde{u}_T^n - u_T^{n-1}) v_T^n
\]

for all \( v_T^n \in S_0^{1,0}(\overline{T}_n) \). Define the error indicator \( \tilde{\eta}_T^n \) by

\[
\tilde{\eta}_T^n = \sum_{K \in \mathcal{T}_n} h_K^2 \left\| a^{\alpha \theta} - a^{\alpha \theta}_{T_n} \right\| \nabla (\tilde{u}_T^n - u_T^{n-1}) ||_K^2
\]

and the data error \( \tilde{\theta}_T^n \) by

\[
\tilde{\theta}_T^n = \sum_{K \in \mathcal{T}_n} h_K^2 \left\| (a^{\alpha \theta} - a^{\alpha \theta}_{T_n}) \cdot \nabla (\tilde{u}_T^n - u_T^{n-1}) ||_K^2
\]

where \( h_K = \min \{ \varepsilon^{-\frac{1}{2}} \text{diam}(\omega), \beta^{-\frac{1}{2}} \} \) and \( a^{\alpha \theta}_{T_n} \) is an approximation of \( a^{\alpha \theta} \) on \( \overline{T}_n \).

Then there are two constants \( c_h \) and \( c_1 \) which only depend on the shape-parameters \( C_{\overline{T}, \mathcal{T}_T} \) such that the following estimates are valid

\[
c_1 \left\{ \left\| \tilde{\eta}_T^n \right\| + \left\| \tilde{\theta}_T^n \right\| \right\} \leq \left\| a^{\alpha \theta} \cdot \nabla (\tilde{u}_T^n - u_T^{n-1}) \right\| \leq c_1 \left\{ \left\| \tilde{\eta}_T^n \right\| + \left\| \tilde{\theta}_T^n \right\| \right\}.
\]

Next we bound the non-linear part of the temporal residual.

Lemma 4.10 (Upper bounds for the non-linear temporal residual). For every \( n \in \{1, \ldots, N_T\} \), the non-linear part of the temporal residual can be bounded from above by

\[
\| R_{\text{nonlin}}(u_T) \|_{L^2(t_{n-1}, t_n; H^{-1}(\Omega))} \leq \sqrt{\frac{T_n}{3}} L_{\lambda T} \| u_T^n - u_T^{n-1} \|
\]

\[
\leq \sqrt{\frac{T_n}{3}} L_{\lambda T}^2 \| u_T^n - u_T^{n-1} \|.
\]

Proof. The assertion follows from (4.4), Lemma 4.1

\[
\int_{t_{n-1}}^{t_n} \| u_T - U^{\alpha \theta} \|^2 \leq \left\| u_T^n - u_T^{n-1} \right\|^2 \int_{t_{n-1}}^{t_n} \left( \theta - \frac{t_n - t_{n-1}}{\tau_n} \right)^2,
\]

and

\[
\int_{t_{n-1}}^{t_n} \left( \theta - \frac{t_n - t_{n-1}}{\tau_n} \right)^2 = \frac{T_n}{6} [2 - 6\nu - (1 + \nu)] \leq \frac{T_n}{3}.
\]

Lemma 4.10 and the estimate

\[
\| u_T^n - u_T^{n-1} \| \leq 2 \sup_{t_{n-1} \leq t \leq t_n} \| u - u_T \| + \sqrt{T_n} \| \partial_t u \|_{L^2(t_{n-1}, t_n)}
\]

yield the following upper bound for the non-linear part of the temporal residual for all parameters \( \varepsilon, \beta, \nu, \) and \( \gamma \).
Lemma 4.11 (Non-linear temporal residual and error). For all parameters \( \varepsilon, \beta, \nu, \) and \( \gamma \) the non-linear part of the temporal residual is bounded from above by the error and the \( L^2 \)-norm of \( \partial_t u \), i.e. for every \( n \in \{1, \ldots, N_T\} \) we have
\[
\| R_{\tau, \text{nonlin}}(u_T) \|_{L^2((t_{n-1}, t_n), H^{-1}(\Omega))} \leq \frac{2\sqrt{T_n}}{3} \nu L \gamma \sup_{t_{n-1} \leq t \leq t_n} \| (u - u_T)(\cdot, t) \| + \frac{T_n}{3} \nu L \gamma \| \partial_t u \|_{L^2((t_{n-1}, t_n))}.
\]

If, on the other hand, \( \nu L \gamma^2 \) is sufficiently small, Lemmas 4.11 and 4.12 imply that the temporal residual is dominated by its linear part.

Lemma 4.12 (Non-linear and linear temporal residual). If \( \bar{\kappa} = 25 (2 + c_{\beta}) \nu L \gamma^2 \) < 1, the temporal residual is dominated by its linear part, i.e. for every \( n \in \{1, \ldots, N_T\} \) we have
\[
\frac{2}{25} (1 - \bar{\kappa}) \left\{ \| R_{\tau, \text{lin}}(u_T) \|_{L^2((t_{n-1}, t_n), H^{-1}(\Omega))} + \| R_{\tau}(u_T) \|_{L^2((t_{n-1}, t_n), H^{-1}(\Omega))} \right\}^2 
\leq \| R_{\tau}(u_T) + R_{\tau}(u_T) \|_{L^2((t_{n-1}, t_n), H^{-1}(\Omega))}.
\]

4.7. Bounding the spatial residual. Replacing in [21, Lemma 3.5] the right-hand side \( f^{n\theta} \) by \( \nu \varphi(U^{n\theta}) g^{n\theta} \) yields the following bounds for the spatial residual.

Lemma 4.13 (Bounds for the spatial residual). For every \( n \in \{1, \ldots, N_T\} \) define a spatial error indicator by
\[
\eta_{T_n}^n = \left\{ \sum_{K \in T_n} h_K^2 \left\| \nu \varphi(U^{n\theta}) g^{n\theta} - \frac{1}{T_n} (u^{n\theta}_{T_n} - u^{n-1\theta}_{T_n}) \right\|^2_K + \frac{1}{2} \sum_{E \in \mathcal{E}_{T_n}} \varepsilon \frac{1}{2} h_E \left\| \int_E (\varepsilon n_E \cdot \nabla U^{n\theta}) \right\|^2_E \right\}^{\frac{1}{2}},
\]
and spatial data errors by
\[
\theta_{T_n}^n = \left\{ \sum_{K \in T_n} h_K^2 \left( \nu \varphi(U^{n\theta}) (g^{n\theta}_{T_n} - g^{n\theta}) + \nu (\varphi(U^{n\theta}) - \varphi(U^{n\theta}_{T_n})) g^{n\theta}_{T_n} \right)^2_K + (a^{n\theta}_{T_n} - a^{n\theta}) \cdot \nabla U^{n\theta} + (b^{n\theta}_{T_n} - b^{n\theta}) U^{n\theta} \right\}_{K}^{\frac{1}{2}},
\]
\[
\Theta_{c\theta, T_n}^n = \left\{ \sum_{K \in T_n} h_K^2 \left( (a^{n\theta} - a^{n\theta}_{T_n}) \cdot \nabla U^{n\theta} \right)^2_K + h_K^2 \left\| \nabla a^{n\theta} \right\|_{L^\infty(K)} \left\| \nabla U^{n\theta} \right\|^2_K \right\}^{\frac{1}{2}}.
\]
Here, \( U^{n\theta} = \theta n^{n\theta}_T + (1 - \theta) u^{n-1\theta}_{T_{n-1}} \) is as in (3.2), \( U^{n\theta}_{T_n} \) is a piecewise constant approximation of \( U^{n\theta} \) on \( T_n \), \( g^{n\theta}, a^{n\theta}, \) and \( b^{n\theta} \) are as in (3.1), and \( g^{n\theta}_{T_n}, a^{n\theta}_{T_n}, \) and \( b^{n\theta}_{T_n} \) are approximations of \( g^{n\theta}, a^{n\theta}, \) and \( b^{n\theta} \) on \( T_n \). Then, on every interval \( (t_{n-1}, t_n) \), the dual norm of the spatial residual can be bounded from above by
\[
\| R_{\tau}(u_T) \| \leq c \left\{ (\eta_{T_n}^n)^2 + (\theta_{T_n}^n)^2 + \sigma_{c\theta} (\Theta_{c\theta, T_n}^n)^2 \right\}^{\frac{1}{2}}
\]
and from below by
\[
\eta_{T_n}^n \leq c \left[ \| R_{\tau}(u_T) \| + \theta_{T_n}^n \right].
\]
Here, the parameter \(\sigma_{c\text{-cip}}\) equals 1 for the continuous interior penalty method and vanishes for the other stabilizations. The above error estimates are robust in the sense that the constants \(c^*\) and \(c_0\) are independent of the parameters \(\varepsilon, \beta, \) and \(\nu\).

### 4.8 A posteriori error estimates

Lemmas 1.4.1, 1.5.1, 1.6, 1.8, 1.10, 1.11, 1.12, and 1.13 yield the following a posteriori error estimates.

**Theorem 4.14 (A posteriori error estimates).** The error between the solution \(u\) of problem (2.3) and the solution \(u_I\) of problem (3.2) is bounded from above by

\[
\begin{align*}
\sup_{0 < t < T} \|u - u_I\|_{L^\infty(\Omega)}^2 + \int_0^T \|u - u_I\|^2 + \int_0^T \|\partial_t(u - u_I) + a \cdot \nabla(u - u_I)\|^2 & \\
\leq c^* \left\{ \|u_0 - \pi_0 u_0\|^2 & \\
+ \sum_{n=1}^{N_T} \tau_n \left[ (\eta_{n,cip}^n)^2 + \|u_{n,cip}^n - u_{n-1,cip}^n\|^2 + (\tilde{\eta}_{n,cip}^n)^2 + \|\tilde{u}_{n,cip}^n\|^2 \right] & \\
+ \sum_{n=1}^{N_T} \tau_n \left[ (\phi_{n,cip}^n)^2 + \sigma_{c\text{-cip}} (\Theta_{n,cip,T_n}^n)^2 \right] & \\
+ \|g - g^{n,q}\|_{L^\infty(0,T;L^\infty(\Omega))} \left( 1 + \int_0^T \|u_I\|^2 \right) & \\
+ \left( \|a - a^{n,q}\|_{L^\infty(0,T;L^\infty(\Omega))} + |b - b^{n,q}|_{L^\infty(0,T;L^\infty(\Omega))} \right) \int_0^T \|u_I\|^2 \right\}^{\frac{1}{2}}
\end{align*}
\]

and on each interval \((t_{n-1}, t_n), 1 \leq n \leq N_T,\) from below by

\[
\tau_n \left[ (\eta_{n,cip}^n)^2 + \|u_{n,cip}^n - u_{n-1,cip}^n\|^2 + (\tilde{\eta}_{n,cip}^n)^2 + \|\tilde{u}_{n,cip}^n\|^2 \right]^{\frac{1}{2}} \\
\leq c^*_n \left\{ \sup_{t - \frac{\tau_n}{2} \leq t \leq t_n} \|u - u_I\|^2 + \int_{t_{n-1}}^{t_n} \|u - u_I\|^2 & \\
+ \int_{t_{n-1}}^{t_n} \|\partial_t(u - u_I) + a \cdot \nabla(u - u_I)\|^2 & \\
+ \tau_n (\phi_{n,cip}^n)^2 & \\
+ \|g - g^{n,q}\|_{L^\infty(t_{n-1}, t_n;L^\infty(\Omega))} \left( 1 + \int_{t_{n-1}}^{t_n} \|u_I\|^2 \right) & \\
+ \left( \|a - a^{n,q}\|_{L^\infty(t_{n-1}, t_n;L^\infty(\Omega))} \right. & \\
\left. \|b - b^{n,q}\|_{L^\infty(t_{n-1}, t_n;L^\infty(\Omega))} \right) \int_{t_{n-1}}^{t_n} \|u_I\|^2 \right\}^{\frac{1}{2}} & \\
+ c_n^* \left\{ \tau_n \sup_{t - \frac{\tau_n}{2} \leq t \leq t_n} \|u - u_I\| + \tau_n \|\partial_t|_{\Omega \times (t_{n-1}, t_n)}\right\}
\]

Here, the functions \(\tilde{u}_{n,cip}^n,\) and the indicators \(\tilde{\eta}_{n,cip}^n,\) and \(\tilde{\theta}_{n,cip}^n,\) are defined in Lemma 4.7, and the quantities \(\eta_{n,cip}^n,\) \(\phi_{n,cip}^n,\) and \(\Theta_{n,cip,T_n}^n,\) are as in Lemma 4.13. The functions \(\tilde{u}_{n,cip}^n,\) and the indicators \(\tilde{\eta}_{n,cip}^n,\) and \(\tilde{\theta}_{n,cip}^n,\) may be dropped if \(\varepsilon \geq 1.\) The parameter \(\sigma_{c\text{-cip}}\) equals 1 for the continuous interior penalty scheme and vanishes for the other stabilizations. For arbitrary parameters \(\varepsilon, \beta, \nu,\) and \(\gamma,\) the constant \(c^*\) is proportional to
\( \nu L \lambda^2 \gamma \) and \( \nu L \gamma T \) with factors depending on the shape parameters \( C_T \) and \( C_{T,T} \), the constant \( c_0 \) is proportional to \( \nu L \lambda^2 \gamma \) with factors depending on the shape parameters \( C_T \) and \( C_{T,T} \) and the polynomial degrees of the finite element functions, and the constant \( c_{**} \) is proportional to \( \nu L \gamma \). If \( \kappa = 2 \nu L \min\{T, \lambda^2\} \gamma < 1 \), the constant \( c_0 \) only depends on \( \kappa \) and the shape parameters \( C_T \) and \( C_{T,T} \). If in addition \( \kappa = 25 (2 + c_0) \nu L \lambda^2 \gamma < 1 \), the constant \( c_0 \) only depends on \( \kappa \), the shape parameters \( C_T \) and \( C_{T,T} \) and the polynomial degrees of the finite element functions and the constant \( c_{**} \) vanishes.
