Fenretinide Inhibits Neutrophil Recruitment and IL-1β Production in Aspergillus fumigatus Keratitis

**Wenyi Zhao, MD,* Chengye Che, MD, PhD,* Kuixiang Liu, MD, PhD,† Jie Zhang, MD, PhD,* Nan Jiang, MD, PhD,* Kelan Yuan, MD,* and Guiqiu Zhao, MD, PhD**

**Purpose:** Fungal keratitis is a major cause of corneal ulcers, resulting in significant visual impairment and blindness. Fenretinide, a derivative of vitamin A, has been shown to suppress inflammation in a multitude of diseases. In this study, we aimed to characterize the effect of fenretinide in Aspergillus fumigatus keratitis of the eye in a mouse model.

**Methods:** In vivo and in vitro experiments were performed in mouse models and THP-1 macrophage cell cultures infected with *A. fumigatus*, respectively. Experimental subjects were first pretreated with fenretinide, and then the effect of the compound was assessed with clinical evaluation, neutrophil staining, myeloperoxidase assay, quantitative polymerase chain reaction (qRT-PCR), and western blot.

**Results:** We confirmed that fenretinide contributed to protection of corneal transparency during early mouse *A. fumigatus* keratitis by reducing neutrophil recruitment, decreasing myeloperoxidase (MPO) levels and increasing apoptosis. Compared with controls, fenretinide impaired proinflammatory cytokine interleukin 1 beta (IL-1β) production in response to *A. fumigatus* exposure with contributions by lectin-type oxidized LDL receptor 1 (LOX-1) and c-Jun N-terminal kinase (JNK).

**Conclusions:** Together, these findings demonstrate that fenretinide may suppress inflammation through reduced neutrophil recruitment and inflammatory cytokine production in *A. fumigatus* keratitis.

**Key Words:** keratitis, *Aspergillus fumigatus*, fenretinide, neutrophils, IL-1β

*(Cornea 2018;37:1579–1585)*

Fungal keratitis, which is mostly caused by *Fusarium solani* and *Aspergillus fumigatus*, may be caused by ocular trauma with vegetative matter.1 Fungal keratitis has a large negative effect on visual health, with up to 60% of corneal ulcers being attributable to fungal infection in developing countries.1,2 Pattern recognition receptors (PRRs) in the cornea are activated by *Aspergillus fumigatus* infection; pattern recognition receptors are responsible for chemokine production and neutrophil recruitment into the corneal stroma. Although neutrophils are essential for fungal killing, they also cause tissue damage that can result in loss of corneal clarity.3,4 Transparency is crucial to the function of the cornea; therefore, it is important to eliminate pathogenic fungi in the cornea, while reducing neutrophil infiltration to maintain transparency. Although new therapies for fungal keratitis have been used in clinical settings, this infection remains a challenge for ophthalmologists because of its generally delayed diagnosis and a dearth of effective drugs and treatment methods.5,6

Fenretinide (4-hydroxy (phenyl) retinamide; 4-HPR) is a synthetic vitamin A derivative that inhibits the activation of the proinflammatory transcriptional factor, nuclear factor (NF)-κB, by upregulating ceramide. It is believed that it is through this mechanism that fenretinide has been shown to suppress inflammation. For instance, it was well established that the imbalance of phospholipid-bound fatty acid is corrected by fenretinide in macrophages by modulating inflammatory cytokine expression through ERK1/2 phosphorylation.7 In addition, fenretinide decreased lipopolysaccharide (LPS)-induced proinflammatory cytokine production, including tumor necrosis factor-α, interleukin 6 (IL-6), and monocyte chemoattractant protein 1, nitric oxide synthase expression, and nitrogen oxide production through activating peroxisome proliferator-activated receptor γ in macrophages.8 Moreover, inflammation and airway hyperresponsiveness induced by ovalbumin were protected by fenretinide, which completely blocked inflammatory cell recruitment into the airways and distinctly reduced goblet cell proliferation.9

However, the role of fenretinide in fungal keratitis has not been previously explored. To this end, we designed and executed in vivo and in vitro experiments in a mouse model...
and THP-1 macrophages cell cultures infected with *A. fumigatus* and pretreated with fenretinide, respectively. We demonstrated that fenretinide contributed to protect corneal transparency of early mouse *A. fumigatus* keratitis by reducing neutrophil recruitment, decreasing myeloperoxidase (MPO) levels, and increasing apoptosis. Fenretinide further impaired proinflammatory cytokine interleukin 1 beta (IL-1β) production in response to *A. fumigatus* exposure with the contribution of lectin-type oxidized LDL receptor 1 (LOX-1) and c-Jun N-terminal kinase (JNK). These findings demonstrate that fenretinide may provide a protective effect for cells and organs infected with early fungal keratitis by suppressing inflammation.

**MATERIALS AND METHODS**

**Preparation of *A. fumigatus***

*A. fumigatus* strain 3.0772 was purchased from the China General Microbiological Culture Collection Center (Beijing, China). The strain was cultured for 3 to 4 days on Sabouraud agar, and suspensions of fresh conidia were scraped from the surface of the medium. Samples were quantified using a hemacytometer and adjusted to a final concentration of $5 \times 10^4$ conidia/μL in phosphate-buffered saline.

**In Vivo Experiments**

Eight-week-old C57BL/6 female mice were purchased from the Changzhou Cavens Laboratory (Jiangsu, China). Mice were treated in accordance with the Statement for the Use of Animals in Ophthalmic and Vision Research by the Association for Research in Vision and Ophthalmology (ARVO). Mice were anaesthetized with 8% chloral hydrate, and then 1 eye was randomly selected from each mouse to receive a subconjunctival injection (5 μL) containing 100 μM of fenretinide (MedChemExpress) or dimethyl sulfoxide (DMSO) as a control 1 day and 2 hours before infection. Eyes were injected when *A. fumigatus* conidia (0.5 $\times 10^5$/μL) were injected into the corneal stroma.

Mice were examined daily with a slit-lamp microscope for corneal opacification and ulceration. Ocular disease was graded using clinical scores ranging from 0 to 12 according to the scoring system proposed by Wu et al.10 Corneas were then harvested for myeloperoxidase assay, quantitative polymerase chain reaction (qRT-PCR), and western blot 1 day after establishment of the mouse models, and eyes were removed at 1 day for immunofluorescence staining.

**In Vitro Experiments**

THP-1 macrophages purchased from the China Center for Type Culture Collection (Wuhan, China) were differentiated with 100 nM of Phorbol 12-myristate 13-acetate (PMA) (Sigma, St. Louis, MO) for 48 hours and then allowed to recover for 24 hours before infection. Macrophages were cultured in RPMI-1640 medium at a density of $1 \times 10^6$/mL. THP-1 macrophages were treated with fenretinide at a final concentration of 10 μM 2 hours before treatment with conidia. Finally, THP-1 macrophages were treated with *A. fumigatus* conidia in 12-well and 6-well plates at a multiplicity of infection of 1 for 4 hours (qRT-PCR) and 16 hours (western blot).

**Immunofluorescence Staining**

Neutrophil recruitment in response to *A. fumigatus* keratitis was visualized with immunofluorescence staining. Mouse eyes were embedded in optimum cutting temperature compound (Tissue-Tek) and frozen in liquid nitrogen until used. The immunofluorescence protocol used in this experiment is described in previous publications.11 The primary antibody used was 10 μg/mL rat anti-mouse NIMP-R14 (Santa Cruz), and Alexa Fluor 488-conjugated goat anti-rabit antibody (1:1000; CST) was used as a secondary antibody.

**Myeloperoxidase (MPO) Assay**

Corneas were cut 1 day after infection. The MPO assay protocol used followed those detailed in a previous publication.12 The slope of the line was determined in relation to the assay units of the MPO/cornea.

**RNA Isolation and qRT-PCR**

The mRNA levels of LOX-1 and IL-1β of THP-1 macrophages and mouse corneas, as well as the mRNA levels of Bel-2, BAX, cytochrome C, caspase-8, caspase-9, caspase-3 of corneas were experimentally determined after infection with *A. fumigatus*. The PCR protocol used in this study is described in previous publications.11 The primer pair sequences were as follows: hLOX-1 F-GCT CCT CCT GAG CGC AAG and R-CAT CTG CTG GTC TTA AAG AAT TG, mLOX-1 F-AGG GCC AGC ACA TCA ACA AGA GC and R-ACG CCC CTG GTC TTA AAG AAT TG, mIL-1β F-GCC AGC AGC ACA TCA ACA AGA GC and R-TGT CCT CAT CCT GGA AGG TCC ACG, mBcl-2 F-GGA CTT GAC ATG GAG ACA ACC, hB-actin F-GCT CCT CCT GAG CGC AAG and R-CAT CTG CTG GAA GGT GGA CA, mCaspase-3 F-AGT TCC TTG TCT ACA AGA CTG G and R-AGC CCC CTG GTC TTA AAG AAT TG, mBax F-CGA GCT GAT CAG AAC CAT CA and R-CTC AGC CCA TCT TCT TCC ACA GCT TA, mCyt-c F-GTA CCA TCC GTA TG and R-AGC CCC TCT TCT GCA GCT TA, mCaspase-8 F-CAT GCC GGG ATG GCA CTC AGC AAG AAC ATG GAG AAG AGA and R-CGT GGG ATA GGA TCC ACC ATC, mCaspase-9 F-CAT GCC GGC TTA GAA ATG GAG AAG AGA and R-CGT GGG ATA GGA TCC ACC ATC, mIL-1β F-GGC ACT GAG CAC TG and R-GAC TCA TCG TAC TGC TGC CAT CAC CA, and mB-actin F-GAT TCG TGG CCA AGC ACT TGA CA, mCaspase-3 F-TGG GCC TGA AAT ACC AGA AGA GC and R-AAA TGA CCC CTG CAT CAC CA, and mB-actin F-GAT TAC TGC TCT GCC TCC TAG C and R-GAC TCA TCG TAC TGC TGC TTG C.

**Western Blotting**

The western blotting protocol that is used to assay corneas and cells is described in previous publications.11

Membranes were incubated accordingly using the following antibodies: anti-LOX-1 (ProteinTech, Chicago, IL), anti-JNK (ProteinTech), anti-pJNK (CST), anti-mIL-1β (R&D, Minneapolis, MN), anti-hIL-1β (CST, Danvers, MA), anti-Bcl-2 (ProteinTech), anti-Bax (ProteinTech), anti-cytochrome c (ProteinTech), anti-cleaved-CASP9 (ProteinTech), anti-cleaved-CASP8 (ProteinTech), anti-cleaved-CASP3 (ProteinTech), and anti-β-actin (CST). The HRP-tagged secondary anti-bodies were purchased from CST.

Statistical Analysis

An unpaired 2-tailed Student t-test was used to determine the statistical significance of the clinical score, MPO assays, qRT-PCR, and western blotting results. Data were represented as mean ± SD and analyzed using GraphPad 5.0 software. Data were considered significant at $P < 0.05$.

RESULTS

**Disease Response After Fenretinide Pretreatment in the Mouse A. fumigatus Keratitis Model**

Images captured with the slit lamp at 1 day after infection illustrate the disease response in control versus fenretinide-pretreated mice. The disease response is represented by a clinical score ($n = 7$/group), which was higher at day 1 for control compared with fenretinide-pretreated mice ($P < 0.05$).

**Fenretinide Pretreatment Reduced Neutrophils Recruitment and MPO Activity in the Mouse A. fumigatus Keratitis Model**

NIMP-R14 was stained in the corneas of control and fenretinide-pretreated mice 1 day after infection (Fig. 2A). The disease response is represented by a clinical score, which was higher at day 1 in controls compared with fenretinide-pretreated mice ($P < 0.05$).
The apparent positive staining (green) in the corneas of fenretinide-pretreated mice indicated a decreased amount of neutrophils compared with control mice. Corneas of fenretinide-pretreated mice exhibited a significant decrease ($P < 0.05$) in MPO levels 1 day after infection compared with the controls (Fig. 2B).

**Fenretinide Inhibited A. fumigatus-Induced Production of IL-1β Through Blockade of the LOX-1/JNK Pathway in the Mice Cornea**

After fenretinide pretreatment, expression of LOX-1 (Fig. 3A; $P < 0.01$) and IL-1β (Fig. 3B; $P < 0.05$) in mRNA levels was significantly downregulated in A. fumigatus-infected mouse corneas. Compared with infection controls, LOX-1, phosphorylated JNK, and pro-IL-1β protein levels in corneas were significantly lower ($P < 0.01$, respectively) at 1 day after infection in fenretinide-pretreated mice (Fig. 3C). Interestingly, JNK was not affected by fenretinide pretreatment (Fig. 3C; $P > 0.05$).

**Fenretinide Pretreatment Increased Apoptosis in the Mouse A. fumigatus Keratitis Model**

The levels of Bcl-2 mRNA (Fig. 5A; $P > 0.05$) and protein (Fig. 5G; $P > 0.05$) were not affected by fenretinide pretreatment. As determined by qRT-PCR, compared with infected controls, LOX-1, phosphorylated JNK, and pro-IL-1β protein levels in corneas were significantly lower at 1 day after infection in fenretinide-pretreated mice. JNK protein levels were not affected by fenretinide pretreatment ($P > 0.05$). The mean values and SDs of 2 independent experiments are shown.

**FIGURE 3.** Fenretinide inhibited Aspergillus fumigatus-induced production of IL-1β through blockade of the LOX-1/JNK pathway in the mice cornea. A, After fenretinide pretreatment, mRNA expression of LOX-1 was significantly downregulated in A. fumigatus-infected mouse corneas ($n = 6$/group) at 1 day after infection. B, mRNA expression of IL-1β was also downregulated. C, Compared with infected controls, LOX-1, phosphorylated JNK, and pro-IL-1β protein levels in corneas were significantly lower at 1 day after infection in fenretinide-pretreated mice. JNK protein levels were not affected by fenretinide pretreatment ($P > 0.05$). The mean values and SDs of 2 independent experiments are shown.

Fenretinide Inhibited A. fumigatus-Induced Production of IL-1β Through Blockade of the LOX-1/JNK Pathway in THP-1 Macrophages

After fenretinide pretreatment, expression of LOX-1 (Fig. 4A; $P < 0.05$) and IL-1β (Fig. 4B; $P < 0.05$) mRNA was significantly downregulated in A. fumigatus THP-1 macrophages stimulated with A. fumigatus. Compared with stimulated controls, LOX-1, JNK, phosphorylated JNK, and pro-IL-1β protein levels were significantly lower in fenretinide-pretreated THP-1 macrophages at 16 hours after A. fumigatus stimulation ($P < 0.01$, respectively) (Fig. 4C). Similar to earlier results, JNK was not affected by pretreatment with fenretinide (Fig. 4C; $P > 0.05$).
infection controls, the mRNA levels of BAX (Fig. 5B; \( P < 0.01 \)), cytochrome c (Fig. 5C; \( P < 0.05 \)), cleaved-caspase-8 (Fig. 5D; \( P < 0.05 \)), cleaved-caspase-9 (Fig. 5E; \( P < 0.05 \)), and cleaved-caspase-3 (Fig. 5F; \( P < 0.05 \)) in fenretinide-pretreated mice corneas were significantly increased. Finally, western blot of the protein levels of BAX, cytochrome c, cleaved-caspase-8, cleaved-caspase-9, and cleaved-caspase-3 in fenretinide-pretreated mice corneas showed significantly increased levels (Fig. 5G; \( P < 0.01 \)). The mean values and SDs of 2 independent experiments are shown.

**DISCUSSION**

Our results demonstrate that fenretinide may suppress inflammation through reduced neutrophil recruitment and inflammatory cytokine production in *A. fumigatus* keratitis. Thus, fenretinide pretreatment significantly improved survival of the acute phase in *Streptococcus suis* infection mouse models by reducing the expression of inflammatory mediators. Finally, Haraoui et al.\(^{15} \) suppressed the acute and chronic stages of a streptococcal cell wall-induced arthritis rat model with orally administered fenretinide in a dose- and time-dependent manner. Together, these observations are consistent with our findings that fenretinide may suppress inflammation caused by infectious diseases.

Compared with the normal disease course of C57BL/6 mice, fenretinide pretreatment contributed to remarkable corneal clarity in early fungal keratitis. Decreased corneal neutrophil recruitment and MPO activity are believed to be responsible for this phenomenon.\(^{16} \) Kanagaratham et al.\(^{9} \) identified that fenretinide prevents recruitment of inflammatory cells to the airways after ovalbumin challenge. Similarly, Dong et al.\(^{17} \) demonstrated that fenretinide treatment blocked tumor angiogenesis with fewer M2-like macrophages in tumor tissues. These findings indicate that fenretinide may reduce inflammatory cell recruitment during the course of an immune response.

Similar to cellular infiltration, fenretinide-treated mice corneas exhibited impaired proinflammatory cytokine IL-1\( \beta \)
production compared with controls. As a critical mediator of the host response to microbial infections, IL-1β is involved in a variety of cellular activities, including cell proliferation, apoptosis, and differentiation. Our results are consistent with reports that proinflammatory cytokine IL-1β, IL-6, cyclooxygenase-2, and prostaglandin E2 levels were found to be decreased in response to A. actinomycetemcomitans by treatment with fenretinide in Raw 264.7 cells.

In addition, we observed in vitro that fenretinide inhibited A. fumigatus-induced production of IL-1β through blockade of the LOX-1/JNK pathway in mouse corneas and THP-1 macrophages. In addition to its role as an oxLDL receptor, LOX-1 is a multiligand receptor that binds to activated platelets, apoptotic cells, C-reactive protein, and bacteria. Previous research has found that the expression of IL-1β, IL-6, CXCL1, and tumor necrosis factor-α was regulated by LOX-1 through p38MAPK and that the cross-talk between TLR4 and LOX-1 elevated ROS levels in A. fumigatus keratitis. JNK is one of MAPKs, includes ERK1/2, JNK, and p38, and plays an important role in the cellular response to proinflammatory cytokines. Previous research has found that production of IL-1β induced by A. fumigatus is JNK dependent, and thus, JNK has an essential role in TLR2-induced corneal inflammation. These findings support the conclusion that fenretinide may suppress inflammation through the LOX-1/JNK/IL-1β pathway as part of the antifungal immune response.

Infection and apoptosis act as a combined inflammatory trigger to clear pathogens and repair host tissue damage during infection. Inflammatory immune responses induce necrotic cell death of immunocytes and release damage-associated molecular patterns, amplifying inflammation. Apoptosis during infection has been shown to shape a suppressive, autoreactive, or protective immune response. For this reason, fenretinide has been suggested as a potential treatment for endometriosis because it promotes apoptosis and increases STRA6 expression potentially reversing pathological loss of retinoid availability. Li et al identified that fenretinide induced apoptosis through activation of caspase-9, caspase-8, and caspase-3 inhibiting the growth of multiple myeloma cells. Raguènez et al observed that apoptosis was induced by the addition of fenretinide through upregulation of caspase-8 expression and activation, increasing apoptotic cell death in metastatic neuroblasts. Fenretinide was identified by Ulukaya et al to induce apoptosis by releasing cytochrome c and activating caspase-9 through a p53-independent pathway.
Furthermore, Mohan et al.\textsuperscript{35} demonstrated that a combination of fenretinide and apigenin promotes apoptosis of malignant neuroblastoma cells by upregulating Bax, downregulating Bel-2, and activating caspase-3. Consistent with each of these findings, our results demonstrated that fenretinide promoted apoptosis by upregulating proapoptotic Bax, releasing cytochrome c, activating caspase-9, caspase-8, and caspase-3 in our mouse model of *A. fumigatus* keratitis.

In conclusion, our results demonstrate that fenretinide, a nontoxic vitamin A derivative, may suppress inflammation by reducing neutrophil recruitment, decreasing inflammatory cytokine production and inducing apoptosis during *A. fumigatus* keratitis. These findings were supported with results from a range of experiments using an *A. fumigatus* keratitis mouse model and cellular methods. As a synthetic all-trans retinoic acid molecule, fenretinide may be a potential treatment to control lesion severity in fungal keratitis.\textsuperscript{36}
