(Received 19 February 2020 and accepted in revised form 8 July 2020)

Abstract. We obtain large and moderate deviation estimates for both sequential and random compositions of intermittent maps. We also address the question of whether or not centering is necessary for the quenched central limit theorems obtained by Nicol, Török and Vaienti [Central limit theorems for sequential and random intermittent dynamical systems. Ergod. Th. & Dynam. Sys. 38(3) (2018), 1127–1153] for random dynamical systems comprising intermittent maps. Using recent work of Abdelkader and Aimino [On the quenched central limit theorem for random dynamical systems. J. Phys. A 49(24) (2016), 244002] and Hella and Stenlund [Quenched normal approximation for random sequences of transformations. J. Stat. Phys. 178(1) (2020), 1–37] we extend the results of Nicol, Török and Vaienti on quenched central limit theorems for centered observables over random compositions of intermittent maps: first by enlarging the parameter range over which the quenched central limit theorem holds; and second by showing that the variance in the quenched central limit theorem is almost surely constant (and the same as the variance of the annealed central limit theorem) and that centering is needed to obtain this quenched central limit theorem.

Key words: large deviations, central limit theorems, stationary stochastic processes, random dynamical systems
2020 Mathematics Subject Classification: 37A50, 37D25, 60F10, 37H99 (Primary)
1. Introduction

The theory of limit laws and rates of decay of correlations for uniformly hyperbolic and some non-uniformly hyperbolic sequential and random dynamical systems (RDSs) has recently seen major progress. Results in this area include the following: in [CR07] strong laws of large numbers and centered central limit theorems (CLTs) are proved for sequential expanding maps; in [AHN+15], polynomial decay of correlations for sequential intermittent systems is proved; in [NTV18], sequential and quenched (self-centering) CLTs for intermittent systems are proved; in [ANV15], annealed versions of a CLT, large deviation principle, local limit theorem and an almost sure invariance principle are proved for random expanding dynamical systems, as well as quenched versions of CLTs, dynamical Borel–Cantelli lemmas, Erdős–Rényi laws and concentration inequalities; in [AA16], necessary and sufficient conditions are given for a CLT without random centering for uniformly expanding maps; and in [BB16b], mixing rates and CLTs are given for random intermittent maps using a Tower construction. Recently, the preprint [BBR19] considered quenched decay of correlation for slowly mixing systems and the preprint [AF20] used martingale techniques to obtain large deviations for systems with stretched exponential decay rates.

In this article, we obtain large deviation estimates for both sequential and random compositions of intermittent maps. We also address the question of whether or not centering is necessary for the quenched CLTs obtained in [NTV18] for RDSs comprising intermittent maps. More precisely, we consider, in the first instance, a fixed deterministically chosen sequence of maps \( \ldots T_{\alpha_n}, \ldots, T_{\alpha_1} \) in the sequential case or a randomly drawn sequence \( \ldots T_{\omega_n}, \ldots, T_{\omega_1} \) with respect to a Bernoulli measure \( \nu \) on \( \Sigma := \{ T_1, \ldots, T_k \}^\mathbb{N} \), where each of the maps \( T_j \) is a Liverani–Saussol–Vaiienti [LSV99] intermittent map of form

\[
T_{\alpha_j}(x) = \begin{cases} 
  x + 2^{\alpha_j}x^{1+\alpha_j}, & 0 \leq x \leq \frac{1}{2}, \\
  2x - 1, & \frac{1}{2} \leq x \leq 1,
\end{cases}
\]

for numbers \( 0 < \alpha_j \leq \alpha < 1 \). We consider the asymptotic behavior of the centered (that is, after subtracting their expectation) sums

\[
S_n := \sum_{k=1}^{n} \varphi \circ (T_{\alpha_k} \circ \cdots \circ T_{\alpha_1})
\]

for sufficiently regular observables \( \varphi \).

Denote by \( m \) the Lebesgue measure on \( X := [0, 1] \) and by \( m(\varphi) \) the integral of \( \varphi \) with respect to \( m \). We will also consider the measure \( \tilde{m} \) given by \( d\tilde{m}(x) = x^{-\alpha}dm \), where \( 0 < \alpha_j \leq \alpha < 1 \). The motivation for introduction of this measure is that, in the case of a stationary system, if \( \alpha_k = \alpha \) for each \( k \), then a natural and convenient measure to use is the invariant measure \( \mu_\alpha \) for \( T_\alpha \), which behaves near zero as \( x^{-\alpha} \). In the stationary case, large deviation estimates are given with respect to \( \mu_\alpha \) and \( m \) in [MN08] for \( \alpha < \frac{1}{2} \) and for all \( 0 \leq \alpha < 1 \) in [Mel09].
In the sequential case of a fixed realization, we are interested in the large deviations of the self-centered sums

\[ m \left\{ x : \frac{1}{n} \sum_{k=1}^{n} \varphi \circ (T_{\alpha_k} \circ \cdots \circ T_{\alpha_1}) - \sum_{k=1}^{n} m(\varphi \circ T_{\alpha_k} \circ \cdots \circ T_{\alpha_1}) \right\} > \epsilon \]

for \( \epsilon > 0 \). We also obtain large deviations with respect to \( \tilde{m} \), which are in a sense sharper. In the sequential case, centering is clearly necessary.

In the annealed case we consider the RDS \( F : \Sigma \times [0, 1] \rightarrow \Sigma \times [0, 1] \) given by \( F(\omega, x) = (\tau \omega, T_{\alpha_1}x) \) for \( \omega = (\alpha_1, \alpha_2, \ldots) \in \Sigma \), where \( \tau \) is the left-shift operator on \( \Sigma \). For \( \nu \) a Bernoulli measure on \( \Sigma \), we suppose that \( \mu \) is a stationary measure for the stochastic process on \([0, 1]\): that is, a measure such that \( \nu \otimes \mu \) is \( F \) invariant. This assumption is valid in the setting we consider. If \( \varphi \) is an observable such that \( \mu(\varphi) = 0 \), we estimate

\[ \nu \otimes \mu \left\{ (\omega, x) : \frac{1}{n} \sum_{k=1}^{n} \varphi \circ (T_{\alpha_k} \circ \cdots \circ T_{\alpha_1}) \right\} > \epsilon \}

In the quenched case, once again assuming that \( \mu(\varphi) = 0 \), we give bounds for

\[ m \left\{ x : \frac{1}{n} \sum_{k=1}^{n} \varphi \circ (T_{\alpha_k} \circ \cdots \circ T_{\alpha_1}) \right\} > \epsilon \}

for \( \nu \)-almost every realization \( \omega \in \Sigma \).

Since the maps we are considering are not uniformly hyperbolic, spectral methods used to obtain limits laws are not immediately available. Our techniques to establish large and moderate deviation estimates are based on those developed for stationary systems, in particular, the martingale methods of [MN08, Mel09].

Using recent work of [AA16] and [HS20], we extend the results of [NTV18] on quenched CLTs for centered observables over random compositions of intermittent maps in two ways, first by enlarging the parameter range over which the quenched CLT holds and second by showing, as a consequence of results in [HS20], that the variance in the quenched CLT is almost surely constant and equal to the variance of the annealed CLT.

We also study the necessity of centering to achieve a quenched CLT using ideas of [AA16] and [ANV15]. The work of [ANV15] together with our observations show that centering is necessary ‘generically’ (in a sense made precise later) to obtain the quenched CLT in fairly general hyperbolic situations.

1.1. Improvements of earlier results. In this paper we improve some results of [NTV18].

- We show that the sequential CLT in [NTV18, Theorem 3.1] and [HL20] holds for the sharp \( \alpha < \frac{1}{2} \) (from \( \alpha < \frac{1}{3} \)) if the variance grows at the rate specified.
- We show that the CLT holds not only with respect to Lebesgue measure \( m \) but also for \( d\tilde{m} = x^{-\alpha} \, dm \), which scales at the origin as the invariant measure of \( T_{\alpha} \).
• In the case of quenched CLTs of [NTV18, Theorem 3.1], using results of Hella and Stenlund [HS20] we show that the variance $\sigma_\omega^2$ is almost surely the same for any sequence of maps and equal to the annealed variance $\sigma^2$.

**Remark 1.1.** After we finished this work, we learned about a preprint by Kor epanov and Leppänen [KL20] in which interesting related results are obtained.

2. **Notation and assumptions**

Throughout this article, $m$ denotes the Lebesgue measure on $X := [0, 1]$ and $\mathcal{B}$ is the Borel $\sigma$-algebra on $[0, 1]$. We consider the family of intermittent maps given by

$$T_\alpha(x) = \begin{cases} x + 2^\alpha x^{1+\alpha}, & 0 \leq x \leq \frac{1}{2}, \\ 2x - 1, & \frac{1}{2} \leq x \leq 1, \end{cases}$$

for $\alpha \in (0, 1)$.

For $\beta_k \in (0, 1)$, denote by $P_{\beta_k} = P_k : L^1(m) \to L^1(m)$ the transfer operator (or Ruelle–Perron–Frobenius operator) with respect to $m$ associated to the map $T_{\beta_k} = T_k$, defined as the ‘pre-dual’ of the Koopman operator $f \mapsto f \circ T_k$, acting on $L^\infty(m)$. The duality relation is given by

$$\int_X P_k f \ g \ dm = \int_X f \ g \circ T_k \ dm$$

for all $f \in L^1(m)$ and $g \in L^\infty(m)$ [BG97, Proposition 4.2.6]. For a fixed sequence $\{\beta_k\}$ such that $0 < \beta_k \leq \alpha$ for all $k$, define

$$\mathcal{T}^\infty := \ldots, T_{\beta_n}, \ldots, T_{\beta_1},$$

$$\mathcal{T}^n := T_{\beta_n} \circ \cdots \circ T_{\beta_m}, \quad \mathcal{T} := \mathcal{T}_1^n,$$

$$\mathcal{P}^n_m := P_{\beta_n} \circ \cdots \circ P_{\beta_m}, \quad \mathcal{P} := \mathcal{P}_1^n.$$  

We will often write, for ease of exposition when there is no ambiguity, $T_{\beta_n} \circ \cdots \circ T_{\beta_m}$ as $T_n \circ \cdots \circ T_m$ and $P_{\beta_n} \circ \cdots \circ P_{\beta_m}$ as $P_n \circ \cdots \circ P_m$.

Since $L^1(m)$ is invariant under the action of the transfer operators, the duality relation extends to compositions

$$\int_X \mathcal{P}^n_k f \ g \ dm = \int_X f \ g \circ \mathcal{T}^n_k \ dm.$$

We will write $\mathbb{E}_m[\varphi \mid \mathcal{F}]$ for the conditional expectation of $\varphi$ on a sub-$\sigma$-algebra $\mathcal{F}$ with respect to the measure $m$. To simplify notation, we might write $\mathbb{E}$ for $\mathbb{E}_m$.

**Remark 2.1.** In [CR07, NTV18] it is shown that

$$\mathbb{E}_m[\varphi \circ \mathcal{T}^{\ell} \mid \mathcal{T}^{-k} \mathcal{B}] = \frac{P_k \circ \cdots \circ P_{\ell+1}(\varphi \cdot \mathcal{P}^{\ell}(1))}{\mathcal{P}^k(1)} \circ \mathcal{T}^{k}$$

for $0 \leq \ell \leq k$. 

One of the main tools for studying sequential and random systems of intermittent maps is the use of cones (see [LSV99, AHN+15, NTV18]). Define the cone $C_2$ by

$$C_2 := \{ f \in C^0((0, 1]) \cap L^1(m) \mid f \geq 0, f \text{ non-increasing,}$$

$$X^{a+1} f \text{ increasing, } f(x) \leq ax^{-m(f)},$$

where $X(x) = x$ is the identity function and $m(f)$ is the integral of $f$ with respect to $m$. In [AHN+15], it is proved that, for a fixed value of $\alpha \in (0, 1)$, provided that the constant $a$ is big enough, the cone $C_2$ is invariant under the action of all transfer operators $P_\beta$ with $0 < \beta \leq \alpha$.

**Notation 2.2.** In general, we will denote the transfer operator with respect to a non-singular† measure $\mu$ (not necessarily a Lebesgue measure) by $P_\mu$. Similarly, the (conditional) expectation will be denoted by $E_\mu$.

Denote the centering with respect to $\mu$ of a function $\phi \in L^1(X, \mu)$ by

$$[\phi]^\mu := \phi - \frac{1}{\mu(X)} \int_X \phi \, d\mu.$$  \hspace{2cm} (2.3)

In particular, for $g(x) := x^{-\alpha}$, denote the measure $gm$ by $\hat{m}$, the corresponding transfer operator by $\hat{P} := P_{gm}$ and the (conditional) expectation by $E_{\hat{m}} := E_{gm}$.

2.1. RDSs. Now we introduce a randomized choice of maps: consider a finite family of intermittent maps of the form (2.1), indexed by a set $\Omega = \{\beta_1, \ldots, \beta_m\} \subset (0, \alpha]$. Given a probability distribution $P = (p_1, \ldots, p_m)$ on $\Omega$, define a Bernoulli measure $P^\otimes N$ on $\Sigma := \Omega^N$ by $P^\otimes N(\omega : \omega_j = \beta_{j_1}, \ldots, \omega_{jk} = \beta_{jk}) = \prod_{i=1}^{k} p_{j_i}$, for every finite cylinder, and extend to the sigma-algebra generated by the cylinders of $\Sigma$ by Kolmogorov’s extension theorem. This measure is invariant and ergodic with respect to the shift operator $\tau$ on $\Sigma$, $\tau : \Sigma \to \Sigma$ acting on sequences by $(\tau(\omega))_k = \omega_{k+1}$. We will denote $P^\otimes N$ by $\nu$ from now on.

For $\omega = (\omega_1, \omega_2, \ldots) \in \Sigma$, define $T_\omega^n := T_{(\tau^n \omega_1)} \circ \cdots \circ T_{\omega_1} = T_{\omega_n} \circ \cdots \circ T_{\omega_1}$. The RDS is defined as

$$F : \Sigma \times X \to \Sigma \times X,$$

$$(\omega, x) \mapsto (\tau \omega, T_{\omega_1} x).$$

The iterates of $F$ are given by $F^n(\omega, x) = (\tau^n(\omega), T_{\omega_1}^n(x))$.

We will also use $\Omega$-indexed subscripts for random transfer operators associated to the maps $T_{\omega_i}$, so that $P_{\omega_i} := P_{T_{\omega_i}}$. We will also abuse notation and write $P_\omega$ for $P_{\omega_i}$ if $\omega = (\omega_1, \omega_2, \ldots, \omega_n, \ldots)$.

A probability measure $\mu$ on $X$ is said to be stationary with respect to the RDS $F$ if

$$\mu(A) = \int_\Sigma \mu(T_{\omega_1}^{-1}(A)) \, d\nu(\omega) = \sum_{\beta \in \Omega} p_\beta \mu(T_{\beta}^{-1}(A))$$

for every measurable set $A$, where $p_\beta$ is the $P$-probability of the symbol $\beta$. This is equivalent to the measure $\nu \otimes \mu$ being invariant under the transformation $F : \Sigma \times X \to \Sigma \times X$.

† The measure $\mu$ is non-singular for the transformation $T$ if $\mu(A) > 0 \implies \mu(T(A)) > 0$. 

**Large deviations and CLTs for intermittent maps**
See Remark 4.5 about the existence and ergodicity of such a stationary measure in our setting.

The annealed transfer operator \( P : L^1(m) \to L^1(m) \) is defined by averaging over all the transformations, i.e.

\[
P = \sum_{\beta \in \Omega} p_\beta P_\beta = \int_\Sigma P_\omega \, d\nu(\omega).
\]

This operator is ‘pre-dual’ to the annealed Koopman operator \( U : L^\infty(m) \to L^\infty(m) \) defined by

\[
(U \phi)(x) := \sum_{\beta \in \Omega} p_\beta \phi(T_\beta x) = \int_{\Sigma} \phi(T_\omega x) \, d\nu(\omega) = \int_{\Sigma} (\tilde{\phi} \circ F)(\omega, x) \, d\nu(\omega)
\]

where \( \tilde{\phi}(\omega, x) := \phi(x) \). The annealed operators satisfy the duality relationship

\[
\int_X (U \phi) \cdot \psi \, dm = \int_X \phi \cdot P\psi \, dm
\]

for all observables \( \phi \in L^\infty(m) \) and \( \psi \in L^1(m) \).

3. Background results and the martingale approximation

In this section, we describe the main technique used to prove some of the limit law results: the martingale approximation, introduced by Gordin [Gor69]. Since there is no common invariant measure for the set of maps \( \{T_k\} \), for a given \( C^1 \) observable \( \phi \) we center along the orbit by

\[
[\phi]_k(\omega, x) := \phi(x) - \int_X \phi \circ T_\omega^k \, dm,
\]

with \( T_\omega^k = \text{Id} \) for \( k = 0 \).

This implies that \( \mathbb{E}_m([\phi]_k \circ T^k) = 0 \) and, consequently, the centered Birkhoff sums

\[
\hat{S}_n := \sum_{k=1}^n [\phi]_k \circ T^k
\]

have zero mean with respect to \( m \). Following [NTV18], define

\[
H_1 := 0 \quad \text{and} \quad H_n \circ T^n := \mathbb{E}_m(\hat{S}_{n-1} \mid B_n) \quad \text{for } n \geq 2 \tag{3.1}
\]

and the (reverse) martingale sequence \( \{M_n\} \) by

\[
M_0 := 0 \quad \text{and} \quad \hat{S}_n = M_n + H_{n+1} \circ T^{n+1},
\]

where the filtration here is \( B_n = T^{-n} B \). Define \( \psi_n \in L^1(m) \) by setting

\[
\psi_n = [\phi]_n + H_n - H_{n+1} \circ T_{n+1};
\]

then \( M_n - M_{n-1} = \psi_n \circ T^n \) and we have that \( \mathbb{E}(M_n \mid B_{n+1}) = 0 \). Thus \( \{\psi_n \circ T^n\} \) is a reverse martingale difference scheme. An explicit expression for \( H_n \) is given by
Large deviations and CLTs for intermittent maps

\[ H_n = \frac{1}{P_n} [P_n ([\varphi]_{n-1} P_{n-1} \mathbf{1}) + P_n P_{n-1} ([\varphi]_{n-2} P_{n-2} \mathbf{1}) + \cdots + P_n P_{n-1} \cdots P_1 ([\varphi]_0 P_0 \mathbf{1})]. \] (3.2)

**Remark 3.1.** The formulas derived so far with \( m \) being the Lebesgue measure actually hold for any measure \( \mu \) that is non-singular for the transformations \( T_\beta \) that were considered. The conditional expectations \( \mathbb{E}_\mu \) will be with respect to \( \mu \) and the transfer operator \( P_\mu \) will be with respect to the measure space \((X, \mu)\). In particular, the centering will have the form
\[ [\varphi]_k(\omega, x) := \varphi(x) - \frac{1}{\mu(X)} \int_X \varphi \circ T_\omega^k \, d\mu, \]
but all other equations are the same, with the notational changes just described.

We collect and extend some results from [NTV18] concerning the properties of \( H_n \), as well as the non-stationary decay of correlations for the sequential system.

First, we state a few formulas for changing from a measure \( m \) to the measure \( g(x) \, dm(x) \) with \( g \in L^1(m) \); for simplicity, we denote this new measure as \( gm \) when there is no possibility of confusion.

**Lemma 3.2.** (Change of measure) We state this result only for the situation we need, but it holds also for any measure \( \mu \), non-singular with respect to \( T \), in place of \( m \) the Lebesgue measure and instead of \( g(x) = x - \alpha \) for any \( g \in L^1(\mu), \, g > 0 \).

Note that \( L^1(gm) = g^{-1} L^1(m) \), so all formulas below make sense for \( \phi \) in the appropriate \( L^1 \)-space:

\[
m(\phi) = m(P_m \phi), \]
\[
P_{gm}(\phi) = g^{-1} P_m (g \phi), \tag{3.3}
\]
\[
g[\phi]^{gm} = [g \phi]^m - \frac{m(g \phi)}{m(g)} [g]^m,
\]
\[
\mathbb{E}_{gm}(\phi \mid B) = \mathbb{E}_m(g \phi \mid B)/\mathbb{E}_m(g \mid B).
\]

Therefore,
\[
(P_{gm})^k_\mu ([\phi]^{gm}) = g^{-1} (P_m)^k_\mu \left( [g \phi]^m - \frac{m(g \phi)}{m(g)} [g]^m \right). \tag{3.4}
\]

**Proof.** The first two properties are standard and follow from the definition of the transfer operator. The third is a direct computation using the notation \((2.3)\).

For the fourth, \( \mathbb{E}_{gm}(\phi \mid B) \) is the function \( \Phi \) that is \( B \)-measurable and \( \int \Phi \psi \, d(gm) = \int \phi \psi \, d(gm) \) for each \( \psi \in L^\infty(B) \). Expanding the left-hand side gives
\[
\int \Phi \psi \, d(gm) = \int \Phi \psi g \, dm = \int \Phi \psi \mathbb{E}_m(g \mid B) \, dm
\]
whereas the right-hand side becomes
\[
\int \phi \psi \, d(gm) = \int \phi \psi g \, dm = \int \mathbb{E}_m(g \phi \mid B) \psi \, dm.
\]

Thus \( \Phi \mathbb{E}_m(g \mid B) = \mathbb{E}_m(g \phi \mid B) \), as claimed. \( \square \)
PROPOSITION 3.3. [NTV18] If \( \phi, \psi \) are both in the cone \( C_2 \) and have the same mean \( \int X \phi dm = \int X \psi dm \), then, by [NTV18, Theorem 1.2],

\[
\|P_n(\phi) - P_n(\psi)\|_{L^1(m)} \leq C_\alpha (\|\phi\|_{L^1(m)} + \|\psi\|_{L^1(m)}) n^{1-1/\alpha} (\log n)^{1/\alpha}.
\]

Moreover [NTV18, Remark 2.5 and Corollary 2.6], for \( \phi \in C^1 \), \( h \in C_2 \) and any sequence of maps \( T^\infty \),

\[
\|P_n([h\phi]^m)\|_{L^1(m)} \leq C_\alpha F(\|\phi\|_{C^1} + m(h)) n^{1-1/\alpha} (\log n)^{1/\alpha},
\]

where \( C_\alpha \) depends only on the map \( T_\alpha \), and \( F: \mathbb{R} \to \mathbb{R} \) is an affine function.

The decay result of Proposition 3.3 for products of elements in the cone with \( C^1 \) observables (see also [LSV99, Theorem 4.1]), follows from Lemma 3.4, which was stated in the proof of [LSV99, proof of Theorem 4.1]. The proof of Lemma 3.4 is given in the Appendix; a different (less transparent) proof is given in [NTV18, Lemma 2.4].

LEMMA 3.4. Suppose that \( \varphi \in C^1 \) and \( h \in C_2 \). Then there exist constants \( \lambda, A, B \in \mathbb{R} \) such that \( (\varphi + A + \lambda x)h + B \) and \( (A + \lambda x)h + B \) are both in \( C_2 \) and hence, if \( \int \varphi h dm = 0 \), then \( \|P_j(\varphi h)\|_{L^1(m)} \leq C \rho(j) \|\varphi h\|_{L^1(m)}, \) where \( \rho(j) \) is the \( L^1(m) \)-decay for centered functions from the cone \( C_2 \).

Note that, in our setting, \( \rho(j) = j^{1-1/\alpha} (\log j)^{1/\alpha} \).

A consequence of Proposition 3.3 is the non-stationary decay of correlations ([NTV18, p. 1130])

\[
\left| \int_X \phi \cdot \psi \circ T_{\omega_n} \circ \cdots \circ T_{\omega_1} dm - m(\phi) \cdot m(\psi \circ T_{\omega_n} \circ \cdots \circ T_{\omega_1}) \right| \\
\leq \|\psi\|_\infty \|P_n^\alpha(\phi) - P_n^\alpha (1 \int_X \phi dm)\|_{L^1(m)}.
\]

Next, we derive decay estimates with respect to the measure \( \tilde{m} \), which are better in \( L^p \), \( p > 1 \), than those for \( m \).

PROPOSITION 3.5. For \( \phi : [0, 1] \to \mathbb{R} \) bounded, \( h \in C_2 \) and \( 1 \leq p \leq \infty \),

\[
\|\tilde{P}_n^\alpha(\phi)\|_{L^\infty(\tilde{m})} \leq m(g) \|\phi\|_{L^\infty(\tilde{m})}.
\] (3.5)

For \( \phi \in C^1([0, 1]) \), \( h \in C_2 \),

\[
\|\tilde{P}_n^\alpha([\varphi^{-1}h\phi]^\tilde{m})\|_{L^1(\tilde{m})} \leq C_\alpha F(\|\phi\|_{C^1} + m(h)) n^{1-1/\alpha} (\log n)^{1/\alpha}
\] (3.6)

and therefore, if \( 1 \leq p \leq \infty \),

\[
\|\tilde{P}_n^\alpha([\varphi^{-1}h\phi]^\tilde{m})\|_{L^p(\tilde{m})} \\
\leq C_\alpha^{1/p} (m(g) \|\phi\|_{L^\infty(\tilde{m})})^{1-1/p} \int F^{1/p} (\|\phi\|_{C^1} + m(h)) n^{(1-1/\alpha)/p} (\log n)^{1/(p\alpha)},
\] (3.7)

where \( C_\alpha \) depends only on \( T_\alpha \) and \( F \) is an affine function.

Note that the \( L^1 \) and \( L^p \) bounds are relevant only for \( \phi \in C^1 \).
Proof. The $L^1$ and $L^\infty$ bounds give (3.7), since

$$\|f\|_{L^p} \leq \|f\|_{L^\infty}^{1/p} \|f\|_{L^1}^{1/p}$$

(3.8)

because

$$\int |f|^p \leq \int \|f\|_{L^\infty}^{p-1} |f| = \|f\|_{L^\infty}^{p-1} \|f\|_{L^1}.$$  

To prove the $L^\infty$ estimate (3.5), note that, by the invariance of the cone $C_2$, $\mathcal{P}^n(g) \in C_2$, so $\mathcal{P}^n(g) \leq x^{-\alpha}m(\mathcal{P}^n(g)) = x^{-\alpha}m(g).$ That is, using (3.3),

$$\mathcal{F}^n(1) = g^{-1} \mathcal{P}^n(g) \leq m(g).$$

Since $-\|\phi\|_{L^\infty} \leq \phi \leq \|\phi\|_{L^\infty} 1$ and $\mathcal{F}^n$ are positive operators, we obtain (3.5).

For (3.6), assume that $\phi \in C^1$ (otherwise, it is clearly satisfied). In view of (3.4),

$$\|\mathcal{F}^n\left([\left(g^{-1}h\right)\phi]^{\overline{m}}\right)\|_{L^1(\overline{m})} = \|g^{-1} \mathcal{P}^n([h\phi]^m) - \frac{m(g)\phi}{m(g)} g^{-1} \mathcal{P}^n([g]^{m})\|_{L^1(\overline{m})}$$

$$= \|\mathcal{P}^n([h\phi]^m) - \frac{m(g)\phi}{m(g)} \mathcal{P}^n([g]^{m})\|_{L^1(m)}$$

$$\leq \|\mathcal{P}^n([h\phi]^m)\|_{L^1(m)} + \left|\frac{m(g)\phi}{m(g)}\right| \|\mathcal{P}^n([g]^{m})\|_{L^1(m)}.$$  

(3.9)

By [NTV18, Lemma 2.3], there is an affine function $\mathcal{F}: \mathbb{R} \to \mathbb{R}$ such that, for $\phi \in C^1([0, 1])$ and $h \in C_2$, we can write $[\phi h]^m = \Psi_1 - \Psi_2$ with $\Psi_1, \Psi_2 \in C_2$ and $\|\Psi_{1,2}\|_{L^1(m)} \leq \mathcal{F}(\|\phi\|_{C^1} + m(h))$. By [NTV18, Theorem 1.2], for an observable $\psi$ in the cone $C_2$ and for any sequence of maps $\mathcal{T}$, we have

$$\int_X \mathcal{P}^n([\psi]^m) \ d\overline{m} \leq C_\alpha \|\psi\|_{L^1(m)} n^{-1/\alpha} (\log n)^{1/\alpha},$$

where $C_\alpha$ depends only on $T_a$. Applying these to (3.9), we obtain (3.6).  

\[ \square \]

**Lemma 3.6.** Let $\phi \in C^1$ and $0 < \alpha < 1$. Then

$$\|H_n \circ \mathcal{T}^n\|_{L^p(m)} \leq \begin{cases} 1 & \text{if } 1 \leq p = \frac{1}{\alpha} - 1, \\ \frac{1 - (1/p)(-1 + 1/\alpha)}{C_\alpha \|\phi\|_{C^1} + m(g)} \times n^{1+(1/p)(1-1/\alpha)} (\log n)^{1/(\alpha p)} & \text{if } p > \max\left\{1, \frac{1}{\alpha} - 1\right\}. \end{cases}$$

(3.10)

\[ (the \ first \ case \ is \ valid \ for \ 0 < \alpha \leq \frac{1}{2}) \] and the same bounds hold for $\|\mathcal{F}_n \circ \mathcal{T}^n\|_{L^p(\overline{m})}$.

where

$$H_n \circ \mathcal{T}^n := \mathbb{E}_m([S_{n-1}]^m|B_n), \quad \mathcal{F}_n \circ \mathcal{T}^n := \mathbb{E}_{\overline{m}}([S_{n-1}]^{\overline{m}}|\mathcal{B}_n), \quad B_n := \mathcal{T}^{-n}B.$$  

Note that, if $1 \leq p < -1 + 1/\alpha$ then $\|H_n \circ \mathcal{T}^n\|_{L^p(m)} \leq C_{p,\alpha} \|\phi\|_{C^1} + m(g)$, although this observation does not play a role in our subsequent analysis.

**Proof.** We prove the statement for $\mathcal{F}_n$. The one for $H_n$ is obtained in the same way, using Proposition 3.3 instead of (3.6).
Using the definition of $\tilde{H}_n$,
\[
\|\tilde{H}_n \circ T^n\|_{L^p(\tilde{m})} = \sum_{k=1}^{n-1} \mathbb{E}_{\tilde{m}}((\phi \circ T^k)\tilde{m}\mid B_n) \leq \sum_{k=1}^{n-1} \|\mathbb{E}_{\tilde{m}}((\phi \circ T^k)\tilde{m}\mid B_n)\|_{L^p(\tilde{m})}.
\]
(3.10)

We will bound each term of the above sum in both $L^1$ and $L^\infty$, and then use (3.8) to obtain an $L^p$-bound.

In $L^\infty$, we have
\[
\|\mathbb{E}_{\tilde{m}}((\phi \circ T^k)\tilde{m}\mid B_n)\|_{L^\infty(\tilde{m})} \leq \|\phi \circ T^k\tilde{m}\|_{L^\infty(\tilde{m})} \leq 2\|\phi\|_{L^\infty(\tilde{m})}.
\]

In $L^1$, we use (2.2) to compute the conditional expectation. Since the conditional expectation preserves the expected value, one can check that the centering holds as written below. We can then use (3.6) for the decay, with $h = P^k(g)$, because $\tilde{P}^k(1) = g^{-1} P^k(g)$.

\[
\|\mathbb{E}_{\tilde{m}}((\phi \circ T^k)\tilde{m}\mid B_n)\|_{L^1(\tilde{m})}
= \|\tilde{P}_n \circ \cdots \circ \tilde{P}_{k+1}(\tilde{P} \circ \tilde{P}^k(1))\tilde{m}\|_{L^1(\tilde{m})}
= \|\tilde{P}_n \circ \cdots \circ \tilde{P}_{k+1}(\tilde{P} \circ \tilde{P}^k(g))\tilde{m}\|_{L^1(\tilde{m})}
\leq C_\alpha F_1(\|\phi\|_{C^1(\tilde{m})} + m(\tilde{P}^k(g)))\alpha(n-k)^{1(1/\alpha)}(\log(n-k))^{1/\alpha}.
\]

Note that $m(\tilde{P}^k(g)) = m(g)$, so the coefficient above does not depend on $k$.

Now apply (3.8), noting that $\|f\|_{L^p(\tilde{m})} \leq \max\{1, \|f\|_{\infty}\}$, to obtain, for $1 \leq p \leq \infty$, that
\[
\|\mathbb{E}_{\tilde{m}}((\phi \circ T^k)\tilde{m}\mid B_n)\|_{L^p(\tilde{m})} \leq C_\alpha(\|\phi\|_{C^1(\tilde{m})} + m(g))\alpha(n-k)^{1(1/\alpha)}(\log(n-k))^{1/\alpha}1/p.
\]

If $p = 1 + 1/\alpha \geq 1$, we bound the last sum in (3.10) by $\sum_{k=1}^{n-1} C_\alpha(\|\phi\|_{C^1(\tilde{m})} + m(g))\alpha(n-k)^{1(1/\alpha)}(\log(n-k))^{1/\alpha}$ to obtain
\[
\|\tilde{H}_n \circ T^n\|_{L^p(\tilde{m})} \leq C_\alpha(\|\phi\|_{C^1(\tilde{m})} + m(g))(\log n)^{1(1/\alpha)}.
\]

If $p > \max\{1, 1 + 1/\alpha\}$, we bound the sum in (3.10) by $\sum_{k=1}^{n-1} C_\alpha(\|\phi\|_{C^1(\tilde{m})} + m(g))\alpha(n-k)^{1(1/\alpha)}(\log(n-k))^{1/\alpha}$ to obtain the bound
\[
\|\tilde{H}_n \circ T^n\|_{L^p(\tilde{m})} \leq \frac{1}{1 - (1/p)(-1 + 1/\alpha)} C_\alpha(\|\phi\|_{C^1(\tilde{m})} + m(g))n^{1(1/p)(1(1/\alpha))}(\log n)^{1/(pa)}.
\]

Note that, if $1 \leq p < -1 + 1/\alpha$, the series converges to a constant $C_{p,\alpha}(\|\phi\|_{C^1(\tilde{m})} + m(g))$. 

A useful remark is the following lower bound for functions in the cone $C_2$.

PROPOSITION 3.7. [LSV99, Lemma 2.4]  For every function $f \in C_2$,
\[
\inf_{x \in [0,1]} f(x) = f(1) \geq \min\left\{a, \left[\frac{\alpha(1 + \alpha)}{a^\alpha}\right]^{1(1/\alpha)}\right\} m(f).
\]

Denote the constant in the above expression by $D_\alpha$. Then $D_\alpha 1 \geq D_\alpha > 0$ for all $n \geq 1$.

\[\dagger\] $\tilde{m}(\phi \circ \tilde{P}^k(1)) = \tilde{m}(\phi \circ T^k)$ because, by the definition of the transfer operator, $\int \phi \circ \tilde{P}^k(1) d\tilde{m} = \int \phi \circ T^k \cdot 1 d\tilde{m}$. 

We will also use Rio’s inequality, taken from [MPU06]. This is a concentration inequality that allows us to bound the moments of Birkhoff sums.

**Proposition 3.8.** [MPU06, Rio17] Let \( \{X_i\} \) be a sequence of \( L^2 \) centered random variables with filtration \( F_i = \sigma(X_1, \ldots, X_i) \). Let \( p \geq 1 \) and define

\[
 b_{i,n} = \max_{i \leq u \leq n} \left\| \sum_{k=i}^{u} \mathbb{E}(X_k | F_i) \right\|_{L^p}.
\]

Then

\[
 \mathbb{E}|X_1 + \cdots + X_n|^{2p} \leq \left( 4p \sum_{i=1}^{n} b_{i,n} \right)^p.
\]

4. **Polynomial large and moderate deviation estimates**

4.1. **Sequential dynamical systems.** Recall that we fixed a sequence \( T^\infty = \cdots T_{\alpha_n}, \ldots, T_{\alpha_1} \), where each of the maps is of the form

\[
 T_{\alpha_j}(x) = \begin{cases} 
 x + 2^{\alpha_j} x^{1+\alpha_j}, & 0 \leq x \leq \frac{1}{2}, \\
 2x - 1, & \frac{1}{2} \leq x \leq 1,
\end{cases}
\]

for \( 0 < \alpha_j \leq \alpha < 1 \). In the first part of this section, we prove that, for such a fixed sequence of maps \( T^\infty \), a polynomial large deviation bound holds for the centered sums.

**Theorem 4.1.** (Sequential large deviation) Let \( 0 < \alpha < 1 \) and \( \varphi \in C^1([0, 1]) \). Then the centered sums satisfy the following large deviation upper bound: for any \( \epsilon > 0 \) and \( p > \max\{1, -1 + 1/\alpha\} \),

\[
 m \left\{ x : \left| \sum_{j=1}^{n} [\varphi(T^j)(x) - m(\varphi(T^j))] \right| > n \epsilon \right\} \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_{\alpha,\|\varphi\|_{C^1}} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p},
\]

where \( C = C_{\alpha,\|\varphi\|_{C^1}} \) is a constant depending on \( \alpha \) and the \( C^1 \) norm of \( \varphi \), but not on the sequence \( T^\infty \).

In particular, for \( p > \max\{1, -1 + 1/\alpha\} \), we obtain the moment estimate

\[
 \mathbb{E}_m \left| \sum_{j=1}^{n} [\varphi(T^j)(x) - m(\varphi(T^j))] \right|^{2p} \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_{\alpha,\|\varphi\|_{C^1}} n^{2p+1-1/\alpha} (\log n)^{1/\alpha}. \tag{4.1}
\]

The same estimates (by the same proof) hold for the measure \( \widetilde{m} \). More precisely,

\[
 \widetilde{m} \left\{ x : \left| \sum_{j=1}^{n} [\varphi(T^j)(x) - \widetilde{m}(\varphi(T^j))] \right| > n \epsilon \right\} \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_{\alpha,\|\varphi\|_{C^1}} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}.
\]
Remark 4.2. Our result gives that the dependence on $\epsilon$ is better in the case $\alpha > \frac{1}{2}$, where we may take $p \to 1$ to obtain

$$m \left\{ x : \left| \sum_{j=1}^{n} [\varphi(\mathcal{T}^j)(x) - m(\varphi(\mathcal{T}^j))] \right| > n\epsilon \right\} \leq \tilde{C}_{\alpha,\varphi}_{c_1} n^{1-\alpha} (\log n)^{1/\alpha} \epsilon^{-2},$$

where $\tilde{C}_{\alpha,\varphi}_{c_1} = (4\alpha/(2\alpha - 1)) C_{\alpha,\varphi}_{c_1}$. The worse bound for $\alpha < \frac{1}{2}$ is probably an artefact of our proof, and not an optimal result.

Remark 4.3. In [Mel09, Corollary A.2], improving [MN08], these bounds are shown to be basically optimal if a single map $T_\alpha$, $0 < \alpha < 1$, is being iterated with respect to its absolutely continuous invariant measure $\mu$: there exists an open and dense set of Hölder observables $\varphi$ such that

$$\mu \left\{ x : \sum_{j=1}^{n} [\varphi(\mathcal{T}^j)(x) - \mu(\varphi(\mathcal{T}^j))] > n\epsilon \right\} \geq C_\epsilon n^{1-1/\alpha} \text{ infinitely often.}$$

As a corollary of Theorem 4.1, we obtain moderate deviation estimates.

**Theorem 4.4. (Sequential moderate deviations)** Let $0 < \alpha < 1$, $\beta := -1 + 1/\alpha$, $\varphi \in C^1([0, 1])$ and $\tau \in (\frac{1}{2}, 1]$. Then the centered sums satisfy the following moderate deviation upper bounds, where $C_{\alpha,\varphi}_{c_1}$ is a constant depending on $\alpha$ and the $C^1$ norm of $\varphi$, but not on the sequence $\mathcal{T}^\infty$.

(a) If $\alpha > \frac{1}{2}$, then, for any $t > 0$,

$$m \left\{ x : \sum_{j=1}^{n} [\varphi(\mathcal{T}^j)(x) - m(\varphi(\mathcal{T}^j))] > n^\tau t \right\} \leq \frac{4}{2 - 1/\alpha} C_{\alpha,\varphi}_{c_1} n^{-\beta + 2(1-\tau)} (\log n)^{1/\alpha} t^{-2}.$$

(b) If $\alpha \leq \frac{1}{2}$, then

$$m \left\{ x : \sum_{j=1}^{n} [\varphi(\mathcal{T}^j)(x) - m(\varphi(\mathcal{T}^j))] > n^\tau t \right\} \leq (4\beta)^\beta C_{\alpha,\varphi}_{c_1} n^{1-1/\alpha} n^{-\beta(2\tau - 1)} t^{-2\beta}.$$

The same estimates (by the same proof) hold for the measure $\tilde{m}$.

**Proof of Theorem 4.1.** We prove the estimate for $m$; the one for $\tilde{m}$ is obtained in the same way.

Fix $n$ and, for $i \in \{1, \ldots, n\}$, define the sequence of $\sigma-$algebras $\mathcal{F}_{i,n} = \mathcal{F}_i = \mathcal{T}^{-(n-i)}(\mathcal{B})$. Note that $\mathcal{F}_i \subset \mathcal{F}_{i+1}$ and hence $\{\mathcal{F}_i\}_{i=1}^n$ is an increasing sequence of $\sigma-$algebras. Take $X_i = [\varphi]_{n-i} \circ \mathcal{T}^{n-i}$, so that $X_i$ is $\mathcal{F}_i$ measurable. Recall that $\psi_j = [\varphi]_j + H_j - H_{j+1} \circ T_{j+1}$ for all $j \geq 0$. We define $Y_i = \psi_{n-i} \circ \mathcal{T}^{n-i}$, $h_i = H_{n-i} \circ \mathcal{T}^{n-i}$ for $i \in \{1, \ldots, n\}$. Hence $Y_i = X_i + h_i - h_{i-1}$. 
Note also that \( \mathcal{G}_i := \sigma(X_1, \ldots, X_i) \subset \sigma(\mathcal{F}_1, \ldots, \mathcal{F}_i) = \mathcal{F}_i \), as \( \sigma(X_i) \subset \mathcal{F}_i \) for all \( i \). Since \( \mathbb{E}(\psi \circ \mathcal{T}^i \mid \mathcal{T}^{-i-1} \mathcal{B}) = 0 \), \( \mathbb{E}(Y_i \mid \mathcal{F}_i) = 0 \) for all \( i > j \). Hence \( \mathbb{E}(Y_i \mid \mathcal{G}_j) = \mathbb{E}(\mathbb{E}(Y_i \mid \mathcal{F}_j) \mid \mathcal{G}_j) = 0 \) for \( i > j \).

For \( p \geq 1 \), define \( b_{i,n} \) as in Rio’s inequality, with \( \mathcal{G}_i \), \( X_j \) as described above, so that

\[
b_{i,n} = \max_{i \leq u \leq n} \left\| X_i \sum_{k=i}^u \mathbb{E}(X_k \mid \mathcal{G}_i) \right\|_{L^p(m)}.
\]

Here all the expectations are taken with respect to \( m \).

Recalling the expression we have for the martingale difference, we can write the sum inside the \( p \)-norm as

\[
\sum_{k=i}^u \mathbb{E}(X_k \mid \mathcal{G}_i) = \sum_{k=i}^u [\mathbb{E}(Y_k \mid \mathcal{G}_i) - \mathbb{E}(h_k \mid \mathcal{G}_i) + \mathbb{E}(h_{k-1} \mid \mathcal{G}_i)] = \left[ \sum_{k=i}^u \mathbb{E}(Y_k \mid \mathcal{G}_i) \right] + \mathbb{E}(h_{i-1} \mid \mathcal{G}_i) - \mathbb{E}(h_u \mid \mathcal{G}_i).
\]

If \( k > i \), then \( \mathbb{E}(Y_i \mid \mathcal{G}_i) = 0 \). This reduces the expression above to

\[
\mathbb{E}(Y_i \mid \mathcal{G}_i) + \mathbb{E}(h_{i-1} \mid \mathcal{G}_i) - \mathbb{E}(h_u \mid \mathcal{G}_i).
\]

We note that \( \| E[f \mid \mathcal{G}] \|_p \leq \| f \|_p \) for any \( f \in L^p(m), p \geq 1 \). Therefore, we may bound \( b_{i,n} \) by \( \max_{i \leq u \leq n} \| X_i \|_\infty (\| Y_i \|_p + \| h_{i-1} \|_p + \| h_u \|_p) \).

We now pick \( p > \max\{1, 1 + 1/\alpha\} \). Since \( \| X_i \|_\infty \) is uniformly bounded by \( 2\| \phi \|_\infty \) and \( Y_i = X_i + h_i - h_{i-1} \), we may bound \( \max_{i \leq u \leq n} \| X_i \|_\infty (\| Y_i \|_p + \| h_{i-1} \|_p + \| h_u \|_p) \) by

\[
\frac{1}{1 - (1/p)(-1 + 1/\alpha)} C_{\alpha,\|\phi\|_{c_1}} n^{1+1/(1/p)(1-1/\alpha)} (\log n)^{1/(p\alpha)},
\]

where \( C_{\alpha,\|\phi\|_{c_1}} \) is independent of \( n \). This is a consequence of Proposition 3.6. Therefore

\[
\left( 4p \sum_{i=1}^n b_{i,n} \right)^p \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_{\alpha,\|\phi\|_{c_1}}^p n^{2p+1/(1/p)(1-1/\alpha)} (\log n)^{1/\alpha},
\]

which, by Rio’s inequality (see Proposition 3.8), is an upper bound for \( \mathbb{E}_m |X_1 + X_2 + \cdots + X_n|^2p \); this proves (4.1). Thus, by Markov’s inequality,

\[
m(|X_1 + \cdots + X_n|^{2p} > n^{2p} \epsilon^{2p}) \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_{\alpha,\|\phi\|_{c_1}}^p \times (n^{-2p} \epsilon^{-2p} n^{2p+1/(1/p)(1-1/\alpha)} (\log n)^{1/\alpha})
\]

\[
\times n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p},
\]

which is the claimed large deviation bound. \( \square \)
Proof of Theorem 4.4. Assume the hypotheses of Theorem 4.4 and let \( \tau \in (\frac{1}{2}, 1] \).

(a) Let \( \alpha > \frac{1}{2} \) so that \(-1 + 1/\alpha < 1\). For \( \tau \in (\frac{1}{2}, 1] \), define \( tn^\tau = n\epsilon \) so that \( \epsilon = tn^{\tau - 1} \).

Then, by Theorem 4.1, for any \( t > 0 \) and \( p > 1 \),

\[
m\left\{ x : \sum_{j=1}^{n} \left| \varphi(T^j)(x) - m(\varphi(T^j)) \right| > n^\tau t \right\} \leq \left( \frac{4p}{1 - (1/p)(-1 + 1/\alpha)} \right)^p C_p^n \left( \varphi \right)_{C^1} n^{-1/\alpha} (\log n)^{1/\alpha} n^{2p(1-\tau) - 2p},
\]

where \( C_p^n \left( \varphi \right)_{C^1} \) is a constant depending on \( \alpha \) and the \( C^1 \) norm of \( \varphi \), but not on the sequence \( T^n \) or \( p \). Fix \( t > 0 \) and let \( p \to 1 \) to obtain, where \( \beta := -1 + 1/\alpha \),

\[
m\left\{ x : \sum_{j=1}^{n} \left| \varphi(T^j)(x) - m(\varphi(T^j)) \right| > n^\tau t \right\} \leq \frac{4}{2 - 1/\alpha} C_p^n \left( \varphi \right)_{C^1} n^{-\beta + 2(1-\tau)} (\log n)^{1/\alpha} t^{-2}.
\]

(b) If \( \alpha \leq \frac{1}{2} \), we take \( p = -1 + 1/\alpha \geq 1 \) and have from Lemma 3.6 that \( \|H_n \circ T^n\|_{L^p(m)} \leq C_p^n \left( \varphi \right)_{C^1 + m(g)} (\log n)^{1+1/(1-\alpha)} \). In the proof of Theorem 4.1, we can then bound \( (4p \sum_{i=1}^{n} b_{i,n})^p \leq (4p)^p C_p^n \left( \varphi \right)_{C^1 + m(g)} n^p (\log n)^{p + p/(1-\alpha)} \) and hence, by Rio’s inequality,

\[
\mathbb{E}_m |X_1 + \cdots + X_n|^2 \leq (4p)^p C_p^n \left( \varphi \right)_{C^1 + m(g)} n^p (\log n)^{p + p/(1-\alpha)}.
\]

Markov’s inequality gives

\[
m(\{X_1 + \cdots + X_n > n\epsilon\}) \leq n^{-2p} \epsilon^{-2p} (4p)^p C_p^n \left( \varphi \right)_{C^1 + m(g)} n^p (\log n)^{p + p/(1-\alpha)}
\]

\[
= n^{-p} \epsilon^{-2p} (4p)^p C_p^n \left( \varphi \right)_{C^1 + m(g)} (\log n)^{p + p/(1-\alpha)}.
\]

Taking \( n\epsilon = n^\tau t \) for \( \tau \in (\frac{1}{2}, 1] \) and the choice \( p = \beta = -1 + 1/\alpha \), we obtain

\[
m(\{X_1 + \cdots + X_n > n^\tau t\}) \leq (4\beta)^p C_p^n \left( \varphi \right)_{C^1 + m(g)} (\log n)^{-1+2/\alpha} n^{-\beta(2\tau - 1)} t^{-2\beta},
\]

as claimed. \( \square \)

4.2. RDSs. Now we prove large deviation estimates for the randomized systems. First, we recall some notation. The annealed transfer operator \( P : L^1(m) \to L^1(m) \) is defined by averaging over all the transformations, i.e.

\[
P = \sum_{\beta \in \Omega} p_{\beta} P_{\beta} = \int_{\Sigma} P_\omega \; dv(\omega).
\]

This operator is dual to the annealed Koopman operator \( U : L^\infty(m) \to L^\infty(m) \) defined by

\[
(U \varphi)(x) = \sum_{\beta \in \Omega} p_{\beta} \varphi(T_\beta x) = \int_{\Sigma} \varphi(T_\omega x) \; dv(\omega) = \int_{\Sigma} \tilde{\varphi}(F(\omega, x)) \; dv(\omega),
\]
where $\tilde{\phi}(\omega, x) := \phi(x)$. The annealed operators satisfy the duality relationship

$$\int_X (U \varphi) \cdot \psi \, dm = \int_X \varphi \cdot P \psi \, dm$$

for all observables $\varphi \in L^\infty(m)$ and $\psi \in L^1(m)$.

**Remark 4.5.** It is easy to see that the averaged transfer operator $P$ has no worse rate of decay in $L^1$ than the slowest of the maps (so better than $n^{1-1/\alpha} (\log n)^{1/\alpha}$, by Proposition 3.3). By taking a limit point of $(1/n) \sum_{k=1}^n P^k(1)$, there is an invariant vector $h$ for $P$ in the cone $C_2$ (see [LSV99]). The measure $\mu = hm$ is stationary for the RDS; by Proposition 3.7, $h \geq D_\alpha > 0$.

Moreover, Bahsoun and Bose [BB16b, BB16a] have shown that there exists a unique absolutely continuous (with respect to the Lebesgue measure) stationary measure $\mu$, and $\nu \otimes \mu$ is mixing—so is also ergodic.

Using the same idea as in the proof of Theorem 4.1, we can obtain an annealed result for the RDS. Note that $P_\mu$, the transfer operator with respect to the stationary measure $\mu$, satisfies $P_\mu 1 = 1$ and so $\|P_\mu \phi\|_\infty \leq P_\mu(\|\phi\|_\infty) = \|P_\mu 1\|_\infty = \|\phi\|_\infty$. An easy calculation shows that $P_\mu(\phi) = (1/h) P(h \phi)$, where $h \in C_2$ is the density of the invariant measure $\mu$ and hence $h \geq D_\alpha m(h)$ is bounded below. As before, this observation allows us to bootstrap, in some sense, the $L^1(\mu)$ decay rate to $L^p(\mu)$ for $p \geq 1$, which is a technique used in [MN08, Mel09].

**Theorem 4.6.** (Annealed large deviation) Let $\varphi \in C^1([0, 1])$ with $\mu(\varphi) = 0$ and let $0 < \alpha < 1$. Then the Birkhoff averages have annealed large deviations with respect to the measure $\nu \otimes \mu$ with rate

$$\left\{ (\omega, x) : \left| \sum_{j=1}^n \varphi \circ T^{j}_\omega(x) \right| \geq n \epsilon \right\} \leq C_{\alpha, p, \|\varphi\|_C^1} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}$$

for any $p > \max\{1, -1 + 1/\alpha\}$.

Note that the Birkhoff sums above are not centered for a given realization $\omega$, only on average over $\Sigma$.

**Proof.** To prove this result, we will use the construction used to prove the annealed CLT in [ANV15]: let $\Sigma_X := X^{\mathbb{N}_0}$, endowed with the $\sigma$-algebra $G$ generated by the cylinders, and the left-shift operator $\tau : \Sigma_X \to \Sigma_X$.

Denote by $\pi$ the projection from $\Sigma_X$ onto the 0th coordinate, that is, $\pi(x) = x_0$ for $x = (x_0, x_1, \ldots)$. We can lift any observable $\varphi : X \to \mathbb{R}$ to an observable on $\Sigma_X$ by setting $\varphi_{\pi} := \varphi \circ \pi : \Sigma_X \to \mathbb{R}$.

Following [ANV15, §4], one can introduce a $\tau$-invariant probability measure $\mu_c$ on $\Sigma_X$ such that $E_{\mu}(\varphi) = E_{\mu_c}(\varphi_{\pi})$, and the law of $S_n(\phi)$ on $\Sigma \times X$ under $\nu \otimes \mu$ is the same as the law of the $n$th Birkhoff sum of $\varphi_{\pi}$ on $\Sigma_X$ under $\mu_c$ and $\tau$; thus it suffices to establish large deviations for the latter.
Now, define
\[ H_n := \sum_{k=1}^{n} P_k^\mu(\phi) : X \to \mathbb{R}. \]

From the relation \( P^\mu(\cdot) = (1/h) P(.h) \), we have that \( \|P^n(\phi)\|_{L^1(\mu)} \leq C_{\alpha,\phi} n^{1-1/\alpha} (\log n)^{1/\alpha} \) because \( \mu(\phi) = 0 \). We calculate \( E_{\mu} |P^\mu(\phi)|^p = E_{\mu} [P^\mu(\phi)]^p \leq \|P^\mu(\phi)\|_{L^1(\mu)} \leq C\alpha,\phi \|P^\mu(\phi)\|_{L^1(\mu)} \leq Ck^{(1-1/\alpha)/p}(\log k)^{1/(p\alpha)} \) and thus \( \|H_n\|_{L^p(\mu)} \) satisfies the bounds of Lemma 3.6.

We lift \( \phi \) and \( H_n \) to \( \Sigma_X \) and denote them by \( \phi_\pi \) and \( H_{n,\pi} \), respectively, and define
\[ \chi_n := \phi_\pi + H_{n,\pi} - H_{n,\pi} \circ \tau : \Sigma_X \to \mathbb{R}. \]

We now continue as in the proof of Theorem 4.1, applying Rio’s inequality. For \( i = 1, \ldots, n \), take the sequences \( \{X_i = \phi_\pi \circ \tau^{n-i}\} \), \( \{Y_i = \chi_{n-i} \circ \tau^{n-i}\} \), and \( G_i = \tau^{-(n-i)}G \). We have \( E_{\mu_c}[Y_i | G_i] = 0 \) for \( i > k \) and so, for \( p > \max\{1, -1 + 1/\alpha\} \),
\[ b_{1,n} = \max_{i \leq n} \left\| X_i \sum_{k=1}^{n} \mathbb{E}_{\mu_c}(X_k | G_i) \right\|_{L^p(\mu_c)} \leq Cn^{1+(1/p)(-1/\alpha)}(\log n)^{1/(p\alpha)}, \]
which gives, as in Theorem 4.1,
\[ \mu_c([X_1 + \cdots + X_n]^{2p} > n^{2p} \epsilon^{2p}) \leq C_{\alpha,\phi,p} n^{1-1/\alpha}(\log n)^{1/(p\alpha)} \epsilon^{-2p}. \]

Using similar ideas, it is possible to obtain an annealed CLT. This has been established already by Young tower techniques in [BB16a, Theorem 3.2]. We include the statement of the annealed central limit and an alternative proof for completeness and to give an expression for the annealed variance.

**Proposition 4.7. (Annealed CLT)** If \( \alpha < \frac{1}{2} \) and \( \phi \in C^1 \) with \( \mu(\phi) = 0 \), then a CLT holds for \( S_n\phi \) on \( \Sigma \times X \) with respect to the measure \( \nu \otimes \mu \): that is, \( (1/\sqrt{n})S_n\phi \) converges in distribution to \( N(0, \sigma^2) \), with variance \( \sigma^2 \) given by
\[ \sigma^2 = -\mu(\phi^2) + 2 \sum_{k=0}^{\infty} \mu(\phi^k U\phi). \]

**Proof.** We will use the results of [ANV15, §4] and [Liv96, Theorem 1.1] (see Theorem 6.3 in the Appendix). We proceed as in Theorem 4.6, using the averaged operators \( U \) and \( P \). As in [ANV15, §4], to \( U \) there corresponds a transition probability on \( X \) given by \( U(x, A) = \sum_{\beta} \mathbb{P}(\beta : T_\beta x \in A) \). The stationary measure \( \mu \) is invariant under \( U \). Extend \( \mu \) to the unique probability measure \( \mu_c \) on \( \Sigma_X := X^{\mathbb{N}_0} = \{x = (x_0, x_1, x_2, \ldots, x_n, \ldots)\} \), endowed with the \( \sigma \)-algebra \( G \) given by cylinder sets, corresponding to \( \mu \) such that \( \{x_n\}_{n \geq 0} \) is a Markov chain on \( (\Sigma_X, G, \mu_c) \) (where \( x_n \) is the \( n \)-th coordinate of \( x \)) induced by the RDS. The left shift \( \tau \) on \( \Sigma_X \) preserves \( \mu_c \). Given \( \phi : X \to \mathbb{R}, \mu(\phi) = 0 \), we define \( \phi_\pi \) on \( \Sigma_X \) by \( \phi_\pi(x_0, x_1, x_2, \ldots, x_n, \ldots) := \phi(x_0) \). As in [ANV15, §4], to prove the CLT for
$S_n(\varphi)$ with respect to $\nu \otimes \mu$ on $\Sigma \times X$, it suffices to prove the CLT for the Birkhoff sum $\sum_{j=0}^{n} \varphi_\tau \circ \tau^k$ with respect to $\mu_c$ on $\Sigma_X$.

We introduce the Koopman operator $\tilde{U}$ and transfer operator $\tilde{P}$ for the map $\tau$ on the probability space $(\Sigma_X, \mathcal{G}, \mu_c)$. We define the decreasing sequence of $\sigma$-algebras $\mathcal{G}_k = \tau^{-k} \mathcal{G}$, and note that $\tilde{P}, \tilde{U}$ satisfy $\tilde{P}^k \tilde{U}^k f = f$ and $\tilde{U}^k \tilde{P}^k f = \mathbb{E}_{\mu_c}(f \mid \mathcal{G}_k)$ for every $\mu_c$-integrable $f$. We note that $\varphi_\tau \in \mathcal{L}^\infty(\mu_c)$. As in [ANV15, Lemma 4.2], we have $\tilde{P}^n(\varphi_\tau) = (P^n \varphi)_\tau$. Thus $\sum_{k=0}^{\infty} \tilde{P}^k \varphi_\tau$ converges in $L^1(\mu_c)$ if $\alpha < \frac{1}{2}$, and therefore $\sum_{k=0}^{\infty} |\int \varphi_\tau \tilde{U}^k \varphi_\tau \, d\mu_c | < \infty$. Thus the result for $\sum_{j=0}^{n} \varphi_\tau \circ \tau^k$ follows from [Liv96, Theorem 1.1]. The stated formula for $\sigma^2$ is also given in [Liv96, Theorem 1.1]. □

We will use the annealed and sequential results to obtain quenched large deviations for random systems of intermittent maps. We denote the Birkhoff sums by $S_{n,\omega}(x)$ to stress the dependence on the realization $\omega$.

**Theorem 4.8.** (Quenched large deviation) Suppose $\varphi \in C^1$ and $\mu(\varphi) = 0$. Fix $0 < \alpha < 1$. Then, given $p > \max\{1, -1 + 1/\alpha\}$ and $\kappa := [4p/(1-\alpha)]$ (rounded up), for $\nu$-almost every realization $\omega \in \Sigma$, the Birkhoff averages have large deviations with polynomial rate, even without centering: there is an $N(\omega)$ such that, for each $\epsilon > 0$,

$$m\{ x : |S_{n,\omega}(\varphi)| > 4n\epsilon \} \leq C_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-\kappa} \text{ for } n \geq N(\omega).$$

Note that the Birkhoff sums $S_{n,\omega}(x)$ above are not centered with respect to the realization $\omega$, only on average over $\Sigma$.

**Remark 4.9.** The point of the above theorem, compared with the sequential Theorem 4.1, is that, for almost each realization, the large deviation estimates hold even without centering. That is, the contribution of the means (with respect to the measure $m$ on $X$) can be ignored for almost each realization $\omega$.

**Proof of Theorem 4.8.** Choose $p > \max\{1, -1 + 1/\alpha\}$ and $\epsilon > 0$. By Theorem 4.1, for all $\omega \in \Sigma$,

$$m\left\{ x : \left| \frac{1}{n} S_{n,\omega}(\varphi)(x) - \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^{j}_\omega) \right| \geq \epsilon \right\} \leq C_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}$$

with $C_{\alpha, \varphi, \delta}$ independent of $\omega$. Integrating over $\Sigma$ with respect to $\nu$, we obtain

$$\nu \otimes m\left\{ (\omega, x) : \left| \frac{1}{n} S_{n,\omega}(\varphi)(x) - \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^{j}_\omega) \right| \geq \epsilon \right\} \leq C_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}.$$

By Theorem 4.6, we also have the annealed estimate for the non-centered sums

$$\nu \otimes m\left\{ (\omega, x) : \left| \frac{1}{n} S_{n,\omega}(\varphi)(x) \right| \geq \epsilon \right\} \leq C_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}.$$
Theorem 4.6 refers to the measure \( \nu \otimes \mu \) but, since \( dm/d\mu = 1/h \leq 1/D_\alpha \), the large deviation estimate applies also to \( \nu \otimes \mu \). Observe now that

\[
\{(\omega, x) : \left| \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| > 2\epsilon \}
\]

\[
\subset \left\{ (\omega, x) : \left| \frac{1}{n} S_{n,\omega} \varphi(x) \right| < \epsilon, \left| \frac{1}{n} S_{n,\omega} \varphi(x) - \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| \geq \epsilon \right\}
\]

\[
\cup \left\{ (\omega, x) : \left| \frac{1}{n} S_{n,\omega} \varphi(x) \right| > \epsilon \right\}.
\]

Thus

\[
\nu \otimes m \left\{ (\omega, x) : \left| \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| > 2\epsilon \right\} \leq K_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}
\]

and, as there is no dependence on \( x \in X \), this means that

\[
\nu \left\{ \omega : \left| \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| > 2\epsilon \right\} \leq K_{\alpha, p, \varphi} n^{1-1/\alpha} (\log n)^{1/\alpha} \epsilon^{-2p}.
\] (4.2)

Denote \( \beta := -1 + 1/\alpha > 0 \).

The proof we give does not give an optimal value of \( \kappa \). In the case \( \beta > 1 \), a simpler proof may be given but the resulting exponent \( \kappa \) is also not optimal and no better than the estimate we give.

Let \( \tau = 2/\beta \) and let \( \delta > 0 \) be small. Choose

\[
\gamma = \frac{1}{2p} \left( \beta - \frac{1}{\tau} \right) - \delta = \frac{\beta}{4p} - \delta \quad \text{and} \quad \kappa = \left[(1 + \beta^{-1})(4p)\right] = \left\lfloor \frac{4p}{1 - \alpha} \right\rfloor.
\]

The notation \( \lfloor x \rfloor \) indicates the smallest integer greater than or equal to \( x \). Then \( (2p\gamma - \beta)\tau < -1 \) and \( \gamma \kappa > \beta \) for \( \delta > 0 \) small enough.

For \( \epsilon = n^{-\gamma} \), the bound (4.2) becomes

\[
\nu \left\{ \omega : \left| \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| > 2n^{-\gamma} \right\} \leq K_{\alpha, p, \varphi} n^{2p\gamma} n^{-\beta} (\log n)^{1/\alpha}.
\]

Consider the subsequence \( n_k := k^\tau \). As \( (2p\gamma - \beta)\tau < -1 \), for \( \nu \)-almost every \( \omega \) there exists an \( N(\omega) \) such that, for all \( n_k > N(\omega) \),

\[
\left| \frac{1}{n_k} \sum_{j=1}^{n_k} m(\varphi \circ T^j_\omega) \right| \leq 2n_k^{\gamma}.
\]

If \( n_k \leq n < n_{k+1} \), then

\[
\left| \frac{1}{n} \sum_{j=1}^{n} m(\varphi \circ T^j_\omega) \right| \leq \frac{1}{n_k} \left| \sum_{j=1}^{n_k} m(\varphi \circ T^j_\omega) \right| + \sum_{j=n_k+1}^{n} m(\varphi \circ T^j_\omega)
\leq 2n_k^{\gamma} + \frac{\|\phi\|_{\infty}}{n_k} |n_{k+1} - n_k|.
\]
There is \( K > 0 \), independent of \( \omega \), depending only on \( \tau, \gamma \) and \( \| \phi \|_\infty \), such that
\[
2n_k^{-\gamma} + \frac{\| \phi \|_\infty}{n_k} \left| n_{k+1} - n_k \right| < 3n_k^{-\gamma} \quad \text{if } k \geq K.
\]
Indeed, \( \lim_{k \to \infty} (n_{k+1}/n_k) = 1 \), \( (1/n_k) \left| n_{k+1} - n_k \right| = O(1/k) \), \( 1/k = O(1/n^{1/\tau}) \) and \( n^{-1/\tau} < n^{-\gamma} \) because \( 1/\tau > \gamma \).

Increase \( N(\omega) \) such that \( n > N(\omega) \) implies \( n \geq K^\tau \) and \( C_{\alpha, p, \phi} n^{\gamma - \beta} (\log n)^{1/\alpha} > 1 \).

We will show that, for \( n > N(\omega) \),
\[
m \left( x : \frac{1}{n} S_{n,\omega} \phi(x) \geq 4\epsilon \right) \leq C_{\alpha, p, \phi} \epsilon^{-k} n^{-\beta} (\log n)^{1/\alpha}.
\]
Suppose \( \epsilon < n^{-\gamma} \). Then \( C_{\alpha, p, \phi} \epsilon^{-k} n^{-\beta} (\log n)^{1/\alpha} \geq C_{\alpha, p, \phi} n^{\gamma - \beta} (\log n)^{1/\alpha} > 1 \) and there is nothing to prove.

If \( \epsilon \geq n^{-\gamma} \) and \( n > N(\omega) \), then, as \( |(1/n) \sum_{j=1}^{n} m(\phi \circ T_{\omega}^j)| < 3\epsilon \),
\[
\left\{ x : \frac{1}{n} S_{n,\omega} \phi(x) \geq 4\epsilon \right\} \subset \left\{ x : \frac{1}{n} S_{n,\omega} \phi(x) - \frac{1}{n} \sum_{j=1}^{n} m(\phi \circ T_{\omega}^j) \geq \epsilon \right\}.
\]
Hence the result holds by Theorem 4.1, as
\[
m \left( x : \frac{1}{n} S_{n,\omega} \phi(x) - \frac{1}{n} \sum_{j=1}^{n} m(\phi \circ T_{\omega}^j) \geq \epsilon \right) \leq C_{\alpha, p, \phi} \epsilon^{-2p} n^{-\beta} (\log n)^{1/\alpha}
\]
and \( 2p < \kappa \).

We remark that the methods used to prove these results in the uniformly expanding case are not applicable here, as they rely on the quasi-compactness of the transfer operator. In the uniformly expanding case, which has exponential large deviations for Hölder observables, it is possible to obtain a rate function.

5. The role of centering in the quenched CLT for RDSs

In this section, we discuss two results: Proposition 5.1, that the quenched variance is the same for almost all realizations \( \omega \in \Sigma \), and Theorem 5.4, that generically one must center the observations in order to obtain a CLT (as opposed to LD Theorem 4.8, where centering did not affect the quenched LD). Note that these hinge on the rate of growth of the mean of the Birkhoff sums; we see that it is \( o(n) \) but not \( o(\sqrt{n}) \). We use the recent paper by Hella and Stenlund [HS20] to extend and clarify the results of [NTV18].

In [NTV18, Theorem 3.1], a self-norming quenched CLT is obtained for \( \nu \)-almost every realization \( \omega \) of the RDS of Theorem 4.6. More precisely, recalling the definition of the centered observables
\[
[\varphi]_k(\omega, x) = \varphi(x) - m(\varphi \circ T_{\omega}^k)
\]
and
\[
\sigma_n^2(\omega) := \int \left[ \sum_{k=1}^{n} [\varphi]_k(\omega, T_{\omega}^k x) \right]^2 dx,
\]
it is shown that
\[
\frac{1}{\sigma_n(\omega)} \sum_{k=1}^{n} [\varphi]_k(\omega, \cdot) \circ T^k_\omega \to N(0, 1)
\]
provided \(\sigma^2_n \approx n^\beta\), with \(\alpha < 1/9\) and \(\beta > 1/(2(1 - 2\alpha))\). Various scenarios under which \(\sigma^2_n(\omega) > n^\beta\) are given in [NTV18]. See also [HIL20].

If the maps \(T_\omega\) preserve the same invariant measure, then it suffices to consider observables with mean zero, since the mean would be the same along each realization. In the setting of [ALS09] this is the case, namely, all realizations preserve Haar measure, and the authors address the issue of whether the variance \(\sigma^2_n(\omega)\) can be taken to be the ‘same’ for almost every quenched realization in the setting of random toral automorphisms. They show that, for almost every quenched realization, the variance in the quenched CLT may be taken as a uniform constant. The technique they use is adapted from random walks in random environments and consists of analyzing an RDS on a product space.

A natural question is whether in our set-up of random intermittent maps, after centering, \(\sigma_n(\omega)\) can be taken to be ‘uniform’ over \(\nu\)-almost every realization. Recent results of Hella and Stenlund [HS20] give conditions under which \((1/n)\sigma^2_n(\omega) \to \sigma^2\) for \(\nu\)-almost every \(\omega\), as well as information about rates of convergence. Note that this is also true in the context of uniformly expanding maps considered by [AA16] using the same method used in [HS20].

A related question is whether we need to center at all. For example, if \(\mu(\varphi) = 0\), where \(\mu\) is the stationary measure on \(X\), then, for \(\nu\)-almost every \(\omega\),
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} [\varphi(T^j_\omega x) - m(\varphi(T^j_\omega)))] \to 0 \quad \text{for } \mu\text{-almost every } x
\]
by the ergodicity of \(\nu \otimes \mu\), but also
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} m(\varphi(T^j_\omega)) \to 0 \quad \text{for } \nu\text{-almost every } \omega,
\]
by the proof of Theorem 4.8. So, for the strong law of large numbers, centering is not necessary. Using ideas of [AA16], we consider the related question of whether centering is necessary to obtain a quenched CLT with almost surely constant variance. We show that the answer to this is positive: to obtain an almost surely constant variance in the quenched CLT, we need to center.

5.1. Non-random quenched variance. For Proposition 5.1, we verify that our system satisfies the conditions SA1, SA2, SA3 and SA4 of [HS20]; then, by [HS20, Theorem 4.1], the quenched variance is almost surely the same, equal to the annealed variance.

PROPOSITION 5.1. Let \(\alpha < \frac{1}{2}\), \(\varphi \in C^1\) and define the annealed variance
\[
\sigma^2 := \lim_{n \to \infty} \frac{1}{n} \| [S_n]^{v \otimes m} \|_{L^2(v \otimes m)}^2 = \lim_{n \to \infty} \frac{1}{n} \| S_n - \int_{\Sigma \times X} S_n \ d\nu \otimes m \|_{L^2(v \otimes m)}^2
\]
\[
= \sum_{k=0}^{\infty} (2 - \delta_{0k}) \lim_{l \to \infty} \int_{\Sigma} [m(\varphi_i \varphi_{i+k}) - m(\varphi_i)m(\varphi_{i+k})] \ d\nu.
\]
If $\sigma^2 > 0$, then, for $\nu$-almost every $\omega$,

$$
\lim_{n \to \infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \left[ \varphi(T_{\omega}^j \cdot) \right]^m \to^d N(0, \sigma^2)
$$

in distribution with respect to $m$.

Remark 5.2. Proposition 4.7 shows that the annealed CLT holds for $\alpha < \frac{1}{2}$ and under the usual genericity conditions the annealed variance satisfies $\sigma^2 > 0$. Thus Proposition 5.1 extends [NTV18, Theorem 5.3] from the parameter range $\alpha < \frac{1}{9}$ to $\alpha < \frac{1}{2}$. Note that [HL20] proved the CLT for $\alpha < \frac{1}{3}$.

Proof of Proposition 5.1. We will verify conditions SA1, SA2, SA3 and SA4 of [HS20, Theorem 4.1] in our setting, with $\eta(k) = Ck^{1-1/\alpha}(\log k)^{1/\alpha}$ in the notation of [HS20].

SA1: If $j > i$, then

$$
\left| \int \varphi \circ T_{\omega}^j(x) \varphi \circ T_{\omega}^i(x) \, dm - \int \varphi \circ T_{\omega}^j(x) \, dm \int \varphi \circ T_{\omega}^i(x) \, dm \right|
$$

$$
= \left| \int \varphi \circ T_{\omega}^{j-i+1}(T_{\omega}^i(x)) \varphi(x) P_{\omega}^i 1 \, dm - \int \varphi P_{\omega}^i 1 \, dm \int \varphi(x) P_{\omega}^i 1 \, dm \right|
$$

$$
\leq C(j-i)^{1-1/\alpha}(\log(j-i))^{1/\alpha}
$$

by the same argument as in the proof of [NTV18, Proposition 1.3].

SA2: Our underlying shift $\sigma : \Sigma \to \Sigma$ is Bernoulli and hence $\alpha$-mixing.

SA3: We need to check [HS20, equation (4)] that

$$
\left| \int \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_1} x) \, dm - \int \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_{r+1}} x) \, dm \right| \leq C \eta(k-r)
$$

and

$$
\left| \int \varphi \cdot \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_1} x) \, dm - \int \varphi \cdot \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_{r+1}} x) \, dm \right| \leq C \eta(k-r).
$$

Using the transfer operators, rewrite

$$
\left| \int \psi \cdot \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_1} x) \, dm - \int \psi \cdot \varphi(T_{\omega_k} T_{\omega_{k-1}} \cdots T_{\omega_{r+1}} x) \, dm \right|
$$

$$
= \left| \int \varphi \cdot P_{\omega_k} P_{\omega_{k-1}} \cdots P_{\omega_1}(\psi) \, dm - \int \varphi \cdot P_{\omega_k} P_{\omega_{k-1}} \cdots P_{\omega_{r+1}}(\psi) \, dm \right|
$$

$$
\leq \|\varphi\|_{\infty} \|P_{\omega_k} P_{\omega_{k-1}} \cdots P_{\omega_{r+1}}[\psi - P_{\omega_r} \cdots P_{\omega_1}(\psi)]\|_{L^1}.
$$

We have to bound this for $\psi$ either $1$ or $\varphi$. If $\psi = 1$, then

$$
\|P_{\omega_k} P_{\omega_{k-1}} \cdots P_{\omega_{r+1}}[1 - P_{\omega_r} \cdots P_{\omega_1}]\|_{L^1} \leq C(k-r)^{1-1/\alpha}(\log(k-r))^{1/\alpha}
$$

with $C$ independent of $\omega$ and $r$ by [NTV18, Theorem 1.2] (see Proposition 3.3) because $1$ and $P_{\omega_k} \cdots P_{\omega_1}$ both lie in the cone and have the same $m$-mean. If $\psi = \varphi$, using Lemma 3.4, we can write $\varphi - (\int \varphi \, dm) 1$ as a difference of two functions in the cone, and then the same decay estimate holds.

SA4: ($\sigma, \Sigma, \nu$) is stationary so SA4 is automatic.  \(\square\)
5.2. Centering is generically needed in the CLT. Now we address the question of the necessity of centering in the quenched CLT. We show that if $\int \varphi \, d\mu_{\beta_i} \neq \int \varphi \, d\mu_{\beta_j}$ for two maps $T_{\beta_i}$, $T_{\beta_j}$, where $\mu_{\beta_i}$ is the invariant measure of $T_{\beta_i}$, then centering is needed: although
\[
\lim_{n \to \infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n} [\varphi(T_{\omega}^j) - m(\varphi(T_{\omega}^j))] \to^d N(0, \sigma^2)
\]
for $\nu$-almost every $\omega$, it is not the case that
\[
\lim_{n \to \infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \varphi(T_{\omega}^j) \to^d N(0, \sigma^2)
\]
for $\nu$-almost every $\omega$.

Our proof has the same outline as that of [AA16], adapted to our setting of polynomial decay of correlations. First, we suppose that the maps $T_{\beta_i}$ do not preserve the same measure. After reindexing, we can suppose that $T_{\beta_1}$ and $T_{\beta_2}$ have different invariant measures and that $\int \varphi \, d\mu_{\beta_1} \neq \int \varphi \, d\mu_{\beta_2}$, a condition satisfied by an open and dense set of observables. Recall that the RDS has the stationary measure $d\mu = h \, dm$, $h \geq D_\alpha > 0$ and we have assumed that $\mu(\varphi) = 0$, $\varphi \in C^1$.

Here are the steps.

- Construct a product RDS on $X \times X$ and prove that it satisfies an annealed CLT for $\bar{\varphi}(x, y) = \varphi(x) - \varphi(y)$ with distribution $N(0, \bar{\sigma}^2)$.
- Observe that almost every uncentered quenched CLT has the same variance only if $2\sigma^2 = \bar{\sigma}^2$, where the original RDS with stationary measure $d\mu = h \, dm$ satisfies an annealed CLT for $\varphi$ with distribution $N(0, \sigma^2)$.
- Observe that the conclusions of [AA16, Theorem 9] hold in our setting and $\bar{\sigma}^2 = 2\sigma^2$ if and only if
\[
\lim_{n \to \infty} \frac{1}{n} \int_X \left( \sum_{k=1}^{n-1} \int_X \varphi \circ T_{\omega}^k h \, dm \right)^2 \, d\nu = 0.
\]
- Use ideas of [AA16] to show the limit above is zero only if a certain function $G$ on $\Sigma$ is a Hölder coboundary, which, in turn, implies that $\int \varphi \, d\mu_{\beta_1} = \int \varphi \, d\mu_{\beta_2}$, which is a contradiction.

Let $\varphi : X \to \mathbb{R}$ be $C^1$, with $\int_X \varphi \, d\mu = 0$, and define $S_n(\varphi) = \sum_{k=0}^{n-1} \varphi(T_{\omega}^k x)$ on $\Sigma \times X$. Recall the standard expression (e.g., see [AA16]) for the annealed variance,
\[
\sigma^2 = \lim_{n \to \infty} \frac{1}{n} \int_\Sigma \int_X [S_n(\varphi)]^2 \, d\mu \, d\nu.
\]

We also consider the product RDS $(\tilde{\Sigma} := \Sigma \times X \times X, \tilde{\nu} := \nu \otimes \mu \otimes \mu, \tilde{T})$ defined on $X^2$ by $\tilde{T}_{\omega}(x, y) = (T_{\omega}x, T_{\omega}y)$. For an observable $\varphi$, define $\tilde{\varphi} : X^2 \to \mathbb{R}$ by $\tilde{\varphi}(x, y) = \varphi(x) - \varphi(y)$ and its Birkhoff sums by $S_n(\tilde{\varphi})$. In Theorem A.1 and Corollary A.2 of the Appendix, we show that $(1/\sqrt{n}) \sum_{j=1}^{n} \tilde{\varphi} \circ \tilde{T}^j \to^d N(0, \tilde{\sigma}^2)$ with respect to $\nu \otimes \mu \otimes \mu$ for some $\tilde{\sigma}^2 \geq 0$. 
The following lemma from [ANV15] is general and does not depend upon the underlying dynamics. It is a consequence of Levy’s continuity theorem (Theorem 6.5 in [Kar93]).

**Lemma 5.3.** [ANV15, Lemma 7.2] Assume that $\sigma^2 > 0$ and $\tilde{\sigma}^2 > 0$ are such that:

1. $S_n(\varphi)/\sqrt{n}$ converges in distribution to $\mathcal{N}(0, \sigma^2)$ under the probability $\nu \otimes \mu$;
2. $S_n(\tilde{\varphi})/\sqrt{n}$ converges in distribution to $\mathcal{N}(0, \tilde{\sigma}^2)$ under the probability $\nu \otimes \mu \otimes \mu$; and
3. $S_n(\omega)(\varphi)/\sqrt{n}$ converges in distribution to $\mathcal{N}(0, \sigma^2)$ under the probability $\mu$, for $\nu$ almost every $\omega$.

Then $2\sigma^2 = \tilde{\sigma}^2$.

Suppose that two of the maps $T_{\beta_1}$ and $T_{\beta_2}$ have different invariant measures. It is possible to find a $C^1\varphi$ such that $\int \varphi d\mu_{\beta_1} \neq \int \varphi d\mu_{\beta_2}$. In fact, $\int \varphi d\mu_{\beta_1} \neq \int \varphi d\mu_{\beta_2}$ for an open and dense set of $\varphi$.

**Theorem 5.4.** Let $\varphi \in C^1$ with $\mu(\phi) = 0$ and suppose that $\int \varphi d\mu_{\beta_1} \neq \int \varphi d\mu_{\beta_2}$. Then it is not the case that

$$\lim_{n \to \infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \varphi(T_{\omega j}^j) \rightarrow \mathcal{N}(0, \sigma^2)$$

for almost every $\omega \in \Sigma$. Hence, the Birkhoff sums need to be centered along each realization.

**Proof.** We follow the counterexample method of [AA16, §4.3]. We show that, in the uncentered case, $2\sigma^2 \neq \tilde{\sigma}^2$. To do this, we use [AA16, Theorem 9], which holds in our setting, namely, $\tilde{\sigma}^2 = 2\sigma^2$ if and only if

$$\lim_{n \to \infty} \int_{\Sigma} \left( \frac{1}{\sqrt{n}} \sum_{k=1}^{n-1} \int_{X} \varphi P_{\omega_k} \cdots P_{\omega_n} (h) \, dm \right)^2 \, d\nu = 0 \quad (5.1)$$

(as in [AA16, §4.3] we change the time direction and replace $(\omega_1, \omega_2, \ldots, \omega_n)$ by $(\omega_n, \omega_2, \ldots, \omega_1)$; this does not affect integrals with respect to $\nu$ over finitely many symbols).

Note that the sequence $P_{\omega_1} P_{\omega_2} \cdots P_{\omega_n} h$ is Cauchy in $L^1$, as $\alpha < \frac{1}{2}$, and

$$\|P_{\omega_1} P_{\omega_2} \cdots P_{\omega_n} (h) - P_{\omega_1} P_{\omega_2} \cdots P_{\omega_n} \cdots P_{\omega_{n+k}} (h)\|_1 \leq Cn^{1-1/\alpha} (\log n)^{1/\alpha}$$

by Proposition 3.3. Thus $P_{\omega_1} P_{\omega_2} \cdots P_{\omega_n} h \to h_\omega$ in $L^1$ for some $h_\omega \in C_2$. This limit defines $h_\omega$, in terms of $\tilde{\omega} := (\ldots, \omega_n, \omega_2, \ldots, \omega_1)$, i.e., $\omega$ reversed in time. We define $G(\omega) := \int_X \varphi h_\omega \, dm$. Note also that $\|P_{\omega_1} P_{\omega_2} \cdots P_{\omega_n} h - h_\omega\|_1 \leq Cn^{-1-\delta}$ for some $\delta > 0$, uniformly for $\omega \in \Sigma$. Hence

$$\int_{\Sigma} \left( \frac{1}{\sqrt{n}} \int_{X} \varphi P_{\omega_k} \cdots P_{\omega_n} h \, dm \right)^2 \, d\nu \leq \int_{\Sigma} \left( \sum_{k=1}^{n-1} \frac{1}{\sqrt{n}} \int_{X} \varphi h_{\tau^k \omega} \, dm + O\left( \sum_{k=1}^{n-1} \frac{1}{(n-k)^{1+\delta}} \right) \right)^2 \, d\nu,$$
which gives, using (5.1), that

$$\lim_{n \to \infty} \int_{\Sigma} \left( \frac{1}{\sqrt{n}} \left( \sum_{k=1}^{n-1} G(\tau^k \omega) \right)^2 \right) d\nu = 0. \tag{5.2}$$

We put a metric on $\Sigma$ by defining $d(\omega, \omega') = s(\omega, \omega')^{-1-\epsilon/2}$, where $s(\omega, \omega') = \inf\{n : \omega_n \neq \omega'_n\}$. With this metric, $\Sigma$ is a compact and complete metric space. Note that $\|h_\omega - h_{\omega'}\|_{L^1} \leq C s(\omega, \omega')^{-\epsilon/2}$ and hence $G(\omega)$ is Hölder with respect to our metric.

As in the Abdulkader–Aimino counterexample, (5.2) implies that $G = H - H \circ \tau$ for a Hölder function $H$ on the Bernoulli shift $(\tau, \Sigma, \nu)$: by [Liv96, Theorem 1.1] (see Theorem A.3 in the Appendix) $G$ is a measurable coboundary, and is therefore a Hölder coboundary, by the standard Livšic regularity theorem (see, for instance, [VO16, §12.2]). Now consider the points $\beta_1^* := (\beta_1, \beta_1, \ldots)$ and $\beta_2^* := (\beta_2, \beta_2, \ldots)$ in $\Sigma$; they are fixed points for $\tau$, and correspond to choosing only the map $T_{\beta_1}$, respectively, only the map $T_{\beta_2}$. This implies that $G(\beta_1^*) = G(\beta_2^*) = 0$ which in turn implies that $\int \varphi \, d\mu_{\beta_1} = \int \varphi \, d\mu_{\beta_2}$, which is a contradiction. \hfill $\Box$

A. Appendix

We will show that the system $\tilde{F}(\omega, x, y) = (\tau \omega, T_{\omega_1}^n x, T_{\omega_1}^n y)$ with respect to the measure $\nu \otimes \mu^2$ on $\Sigma \times [0, 1]^2$ (recall that $\nu := \mathbb{P} \otimes \mathbb{N}$ and $\mu$ is a stationary measure of the RDS) has summable decay of correlations in $L^2$ for $\alpha < \frac{1}{2}$, and, as a corollary, it satisfies the CLT.

THEOREM A.1. Suppose that, for $\omega \in \Sigma$, $h = d\mu / dm \in C_2$ and each $\phi \in C^1$ with $m(\phi h) = 0$,

$$\|P_{\omega_n} \cdots P_{\omega_1} (\phi h)\|_{L^1(\mu)} \leq C \rho(n)(\|\phi\|_{C^1} + m(h))$$

(that is, the setting of Proposition 3.3).

Then there is a constant $\tilde{C}$, independent of $\omega$, such that, for each $\psi \in C^1(X \times X)$ and $\varphi \in L^\infty(X \times X)$ with $\mu \otimes \mu)(\psi) = 0$, one has

$$\left| \int \psi(T_{\omega_n}^n x, T_{\omega_n}^n y) \varphi(x, y) \, d\mu(x) \, d\mu(y) \right| \leq \tilde{C} \rho(n)\|\varphi\|_{L^\infty(\|\varphi\|_{C^1} + 1)}.$$  

Proof. Since $X \times X$ is compact, $\psi$ is uniformly $C^1$ in both variables in the sense that $\psi(x_0, y)$ is uniformly $C^1$ for each $x_0$ and, similarly, for $\psi(x, y_0)$. We want to estimate

$$I := \int \psi(T_{\omega_n}^n x, T_{\omega_n}^n y) \varphi(x, y) \, d\mu(x) \, d\mu(y).$$
Large deviations and CLTs for intermittent maps

Define
\[ 
\overline{\psi}(x) := \int \psi(x, y) \, d\mu(y), \quad h_x(y) := \psi(x, y) - \overline{\psi}(x). 
\]
Then \( \overline{\psi}, h_x \in C^1(X) \), with \( C^1 \)-norms bounded by \( 2\|\psi\|_{C^1} \), uniformly with respect to \( x \).

We can write \( I \) as
\[
I = \int \varphi(T^n_{\omega} x, T^n_{\omega} y)[\psi(x, y) - \overline{\psi}(x, y)] \, d\mu(x) \, d\mu(y) \\
+ \int \varphi(T^n_{\omega} x, T^n_{\omega} y) \overline{\psi}(x, y) \, d\mu(x) \, d\mu(y) .
\]

Now define \( g_{\omega, x}(y) := \varphi(T^n_{\omega} x, y) \). Then (note that \( \int h_x(y)h(y) \, dm(y) = 0 \))
\[
|I_1| = \left| \int \left( \int g_{\omega, x}(T^n_{\omega} y)h_x(y)h(y) \, dm(y) \right) \, d\mu(x) \right| \\
= \left| \int \left( \int g_{\omega, x}(y)P^n_{\omega}(h_x(y)h(y)) \, dm(y) \right) \, d\mu(x) \right| \\
\leq \|\varphi\|_{L^\infty} \sup_x \|P^n_{\omega}(h_x(y)h(y))\|_{L^1(m(y))} \\
\leq C'\|\varphi\|_{L^\infty}(\|\psi\|_{C^1} + m(h))\rho(n)
\]
by the hypothesis.

Similarly, define \( k_{\omega, y}(x) := \varphi(x, T^n_{\omega} y) \) so (again, \( \int \overline{\psi}(x)h(x) \, dm(x) = 0 \))
\[
|I_2| = \left| \int \left( \int k_{\omega, y}(T^n_{\omega} x)\overline{\psi}(x) \, d\mu(x) \right) \, d\mu(y) \right| \\
= \left| \int \left( \int k_{\omega, y}(x)P^n_{\omega}(\overline{\psi}(x)h(x)) \, dm(x) \right) \, d\mu(y) \right| \\
\leq \|\varphi\|_{L^\infty} \|P^n_{\omega}(\overline{\psi}(x)h(x))\|_{L^1(m(x))} \\
\leq C'\|\varphi\|_{L^\infty}(\|\psi\|_{C^1} + m(h))\rho(n).
\]
These imply that \( |I| \leq 2C'\|\varphi\|_{L^\infty}(\|\psi\|_{C^1} + m(h))\rho(n) \). \( \square \)

**Corollary A.2.** Under the assumptions of Theorem A.1, for \( \psi \in C^1(X \times X) \) with \( (\mu \otimes \mu)(\psi) = 0, (1/\sqrt{n}) \sum_{k=1}^n \psi \circ \tilde{F}^k(\omega, x, y) \) satisfies a CLT with respect to \( \nu \otimes \mu \otimes \mu \), that is,
\[
\frac{1}{\sqrt{n}} \sum_{k=1}^n \psi \circ \tilde{F}^k(\omega, x, y) \to^d N(0, \tilde{\sigma}^2)
\]
in distribution for some \( \tilde{\sigma}^2 \geq 0 \).
Proof. Let $Q$ be the adjoint of $\bar{F}(\omega, x, y) = (\sigma \omega, T_{\omega_1}x, T_{\omega_1}y)$ with respect to the invariant measure $\nu \otimes \mu \otimes \mu$ on $\Sigma \times X^2$. Then
\[
\int \varphi \circ \bar{F}(\omega, x, y)\psi(\omega, x, y) \, d\mu(x) \, d\mu(y) \, d\nu(\omega)
\]
\[
= \int \varphi(\omega, x, y)(Q\psi)(\omega, x, y) \, d\mu(x) \, d\mu(y) \, d\nu(\omega)
\]
for $\phi \in L^\infty(\Sigma \times X \times X)$. Iterating, we have
\[
\int \varphi \circ \bar{F}(\omega, x, y)\psi(\omega, x, y) \, d\mu(x) \, d\mu(y) \, d\nu(\omega)
\]
\[
= \int \varphi(\omega, x, y)(Q^n\psi)(\omega, x, y) \, d\mu(x) \, d\mu(y) \, d\nu(\omega).
\]
Taking $\varphi = \text{sign}(Q^n\psi)$, we see from Theorem A.1 that $\|Q^n\psi\|_{L^1} \leq C \rho(n)$.

The proof now follows, as in Proposition 4.7, from [Liv96, Theorem 1.1] (see Theorem A.3). \qed

Proof of Lemma 3.4. Let $f_1 = (\varphi + \lambda x + A)h + B$ and $f_2 = (A + \lambda x)h + B$.

First, we show that $f_1 \in C_2$. It is clear that $f_1 \in C^1(0, 1) \cap L^1(m)$. Choose $\lambda < 0$ such that $|\lambda| > \|\varphi\|_L^\infty$ and $A > 0$ large enough so that
\[
\varphi + \lambda x + A > 0.
\]

This ensures that $f_1 \geq 0$ for any value of $B \geq 0$. Now note that
\[
(\varphi + \lambda x + A)' = \varphi' + \lambda \leq 0
\]
so $\varphi + \lambda x + A$ is decreasing. Since both $\varphi + \lambda x + A$ and $h$ are positive and decreasing, we obtain that $f_1$ is decreasing as well. We show now that $x^{\alpha+1}f_2$ is increasing. Since $h \in C_2$, $h$ is non-increasing so $h'$ exists $m$-almost everywhere (a.e.) and $h' \leq 0$ $m$-a.e. Then $(x^{\alpha+1}h)'$ exists $m$-a.e. as well, and we can compute this derivative as
\[
(x^{\alpha+1}h)' = (\alpha + 1)x^\alpha h + x^{\alpha+1}h' \geq 0
\]
because it is increasing.

We compute now the derivative of $x^{\alpha+1}f_2$, i.e.
\[
(x^{\alpha+1}[(\varphi + \lambda x + A)h + B])' = (\alpha + 1)x^\alpha \varphi h + x^{\alpha+1}\varphi'h + x^{\alpha+1}\varphi'h' + (\alpha + 2)x^{\alpha+1}h\lambda
\]
\[
+ \lambda x^{\alpha+2}h' + (\alpha + 1)Ax^\alpha h + Ax^{\alpha+1}h' + (\alpha + 1)x^\alpha B.
\]

We group terms conveniently: note that
\[
(\alpha + 1)x^\alpha \varphi h + (\alpha + 1)Ax^\alpha h + x^{\alpha+1}\varphi'h + Ax^{\alpha+1}h'
\]
\[
= (\varphi + A)[(\alpha + 1)x^\alpha h + h'x^{\alpha+1}] \geq 0
\]
m-a.e., since the term in the square brackets corresponds to $(x^{\alpha+1}h)' \geq 0$. The term $\lambda x^{\alpha+2}h'$ is non-negative $m$-a.e. since $\lambda$, $h' \leq 0$. Since $0 \leq h(x)x^\alpha \leq am(h)$, we have $0 \leq -x^{\alpha+1}h' \leq (\alpha + 1)x^\alpha h \leq (\alpha + 1)am(h)$ and then the terms $(\alpha + 2)\lambda x^{\alpha+1}h + x^{\alpha+1}h\varphi'$
are bounded. Thus, we can take $B > 0$ big enough so that
\[(\alpha + 1)x^\alpha B \geq (\alpha + 2)\lambda x^{\alpha+1}h + x^{\alpha+1}h \varphi'.\]

With this, we have that $(x^{\alpha+1}h)' \geq 0$ and so $x^{\alpha+1}h$ is increasing.

Finally, we check that $f_1(x)x^\alpha \leq am(f_1)$. Using that $h(x)x^\alpha \leq am(h)$,
\[
[(\varphi + \lambda x + A)h + B]x^\alpha \leq (\varphi + \lambda x + A)hx^\alpha + B \leq \sup(\varphi + \lambda x + A)am(h) + B.
\]

On the other hand, $am((\varphi + \lambda x + A)h + B) \geq a \inf(\varphi + \lambda x + A)m(h) + aB$, so it suffices to have
\[
\sup(\varphi + \lambda x + A)am(h) + B \leq a \inf(\varphi + \lambda x + A)m(h) + aB
\]

\[\iff B \geq \frac{a}{a-1}[\sup(\varphi + \lambda x + A) - \inf(\varphi + \lambda x + A)]m(h).\]

Thus, we see that $f_1 \in C_2$. The proof that $f_2 \in C_2$ is the same, taking $\varphi(x) \equiv 0$. \qed

**Theorem A.3.** (Special case of [Liv96, Theorem 1.1]) Assume that $T : Y \to Y$ preserves the probability measure $\eta$ on the $\sigma$-algebra $\mathcal{B}$. Denote by $P$ its transfer operator.

If $\varphi \in L^\infty(\eta)$ with $\eta(\varphi) = 0$ and $\sum_k \|P^k \varphi\|_{L^1(\eta)} < \infty$, then a CLT holds for $S_n \varphi := \sum_{k=1}^n \varphi \circ T^k$ with respect to the measure $\eta$, that is, $(1/\sqrt{n})S_n \varphi$ converges in distribution to $N(0, \sigma^2)$. The variance is given by
\[
\sigma^2 = -\eta(\varphi^2) + 2 \sum_{k=0}^\infty \eta(\varphi \cdot \varphi \circ T^k).
\]

In addition, $\sigma^2 = 0$ if and only if if $\varphi \circ T$ is a measurable coboundary, that is, $\varphi \circ T = g - g \circ T$ for a measurable $g$.
