(Dated: July 1, 2015)

The production of heavy quarkonia is a powerful tool to test our understanding of strong interaction dynamics. It is well-known that the dominant production mechanism for heavy quarkonia with large transverse momentum is fragmentation. In this work we, analytically, calculate the QCD leading order contribution to the process-independent fragmentation functions (FFs) for gluon to split into the vector ($J/\psi$) and pseudoscalar ($\eta_c$) $S$-wave charmonium states. The analyses of this paper differ in which we present, for the first time, an analytical form of the $g \rightarrow J/\psi$ FF using a different approach (Suzuki’s model) in comparison with other results presented in literatures, where the Braaten’s scheme was used and the two-dimensional integrals were presented for the gluon FFs which must be evaluated numerically. The universal fragmentation probability for the $g \rightarrow J/\psi$ is about $10^{-6}$ which is in good consistency with the result obtained in the Braaten’s model.

I. INTRODUCTION

Heavy quarkonia, as the bound states of a heavy quark and antiquark, are the simplest particles when the strong interactions are concerned. Their production has a long history of theoretical calculations and experimental measurements [1], especially, their production at high-energy colliders has been the subject of considerable interest during the past few years. Nevertheless, the production of heavy quarkonium is still puzzling us after almost forty years since the discovery of $J/\psi$. New data have been taken at $e^+e^-$, $ep$ and $pp$ colliders, and a wealth of fixed-target data also exist and with the advances in theory and tremendous amount of precise data from the Large Hadron Collider (LHC), it is an excellent time to study the physics of heavy quarkonium production. Nowadays, it is well-known that the dominant mechanism to produce the heavy quarkonia at high transverse momentum is fragmentation. The production of a parton with a large transverse momentum which subsequently decays to form a jet containing the expected hadron [2]. It is hence important to obtain the corresponding fragmentation function (FF), in order to properly estimate the production rate of a specific quarkonium state. Because of the simple internal structure of heavy quarkonia the perturbative QCD approximations to their FFs are well-defined in the nonrelativistic QCD (NRQCD) factorization framework [3]. To calculate the FFs, beside the current phenomenological approaches which are based on the $\chi^2$ analysis of experimental data (see our previous work [4]), there are two theoretical schemes which are based on the fact that the FFs for hadrons containing heavy quarks can be computed analytically using the perturbative QCD (pQCD) [5, 6]. In these theoretical schemes the QCD improved parton model provides a great theoretical frame to extract the FFs. The first scheme for the inclusive production of heavy quarkonium has been developed by Bodwin, Braaten, and Lepage, who proposed a method on the basis of pQCD and the nonrelativistic quark model [3, 7]. In this model, the FF of a heavy quark $Q$ into the pseudoscalar or vector heavy-light mesons $Q\bar{q}$ is defined as the cross section for producing a $Q\bar{q}$-meson plus a light quark $q$ with total four-momentum $K^\mu$, divided by the cross section for producing an on-shell $Q$ with the same three-momentum $K$, while $K_0 \rightarrow \infty$. The fragmentation function in the Braaten’s model is defined as

$$D(z, \mu_0) = \frac{1}{16\pi^2} \int ds \lim_{K_0 \rightarrow \infty} \frac{\sum |M|^2}{\sum |M_0|^2}$$

(1)

where $s = K^2$ is the invariant mass of the meson, $M$ is the matrix element for producing mesons plus a light quark $q$, and $M_0$ is the matrix element for producing an on-shell $Q$. Here, $D$ stands for the fragmentation function and $z$ is the fragmentation parameter which refers to the longitudinal momentum fraction of the quarkonium and $\mu_0$ is a fragmentation scale. This model was applied to the fragmentation processes $b \rightarrow B_c$ and $b \rightarrow B_s^*$ in Ref. [8]. Another elaborate model is proposed by Suzuki [9, 10] which is based on the convenient Feynman diagrams and the wave function of the respective heavy meson, where the wave function includes the effect of long-distance in the fragmentation. In this model, the heavy FFs are calculated using a diagram similar to that in Fig. [8] so the analytical expression of FFs depends on the transverse momentum $p_T$ of the parton which appears as a phenomenological parameter (e.g. see Eq. [8]), while in the Braaten’s model the integrations over all freedom degrees are performed.

Note that, as soon as more than one hadron is appeared

*Electronic address: mmoosavi@yazd.ac.ir
in a hard scattering process, it is necessary to take into account the transverse momentum \( p_T \) of the partons. For example, transverse momentum dependent FFs show up explicitly in several semi-inclusive cross sections, in particular in azimuthal asymmetries. In the calculation of QCD corrections to these cross sections, the inclusion of the \( p_T \) dependent FFs will be essential. Experimentally, based on the 1992-1993 run (run 1A), the CDF collaboration published data on their first measurement of the B-meson differential cross section \( d\sigma/dp_T \) for the exclusive decays \( B^+ \rightarrow J/\psi K^+ \) and \( B^0 \rightarrow J/\psi K^{*0} \) \cite{11}. In \cite{12}, the \( p_T \) distribution \( d\sigma/dp_T \) is considered and the theoretical predictions are compared with the CDF data \cite{11} for which \( 5 \text{GeV}<p_T<20\text{GeV} \). This is our main motivation to study the transverse momentum dependent FFs in the Suzuki’s model. In Ref. \cite{13}, using this model we computed an exact analytical expression of the fragmentation function for c-quark to split into the \( J/\psi K \) mesons to LO. There, we investigated that there is an excellent consistency between our result and the current well-known phenomenological models and also with the experimental data from BELLE and CLEO.

In high energy processes, the main contribution of charmonium production results from gluon fragmentation, while the charm quark fragmentation contribution is much too small \cite{14, 15}. This point was confirmed by the comparison between the theoretical predictions and the CDF J/\( \psi \) production data. Therefore, in this work using the Suzuki’s model we focus on the gluon fragmentation into a vector (J/\( \psi \)) and pseudoscalar (\( \eta_c \)) S-wave charmonium to leading order of perturbative QCD and we present, for the first time, an analytical expression for the transverse momentum dependent fragmentation functions of \( g \rightarrow \eta_c, J/\psi \).

Note that, in the past few years the \( g \rightarrow \eta_c, J/\psi \) FFs have been calculated numerically, using the Braaten’s model \cite{2, 10}. In these papers, due to the lengthy and cumbersome expression of the \( g \rightarrow J/\psi FF \) the two-dimensional integrals have been presented that must be evaluated numerically. Moreover, since in the Braaten’s model integrations over all freedom degrees are performed, then the presented FFs are independent of the transverse momentum of the initial gluon.

Our analytical expression for the \( g \rightarrow J/\psi FF \) will be compared with the numerical result presented in \cite{10}. Using the FF obtained, we also calculate the first two moments of FF which are of phenomenological interest and subject to experimental determination. They correspond to the \( g \rightarrow J/\psi \) branching fraction and the average energy fraction of the J/\( \psi \) meson which receives from the gluon.

This paper is organized as follows. In Sec. \( \text{III} \) we explain our theoretical approach to calculate the FFs using the pQCD. Our analytical results of the \( g \rightarrow \eta_c, J/\psi \) FFs will be presented in the Suzuki’s model. In Sec. \( \text{III} \) our numerical results for the gluon FFs are presented. Our conclusion is summarized in Sec. \( \text{IV} \).

\section{Gluon Fragmentation into S-Wave Charmonium: Perturbative QCD Scheme}

The theoretical schemes for calculating the charmonium FFs are based on the fact that the FFs for hadrons containing a heavy quark can be computed theoretically using perturbative QCD \cite{2, 3, 6, 17}. The \( g \rightarrow \eta_c, J/\psi \) FFs have been already calculated in Refs. \cite{2, 10}; using the Braaten’s model where the fragmentation function is defined as in \cite{11}. In Ref. \cite{2}, authors considered the typical Feynman diagrams contributed to the production of charmonium states at the order \( \alpha_s^3 \) (Fig. \ref{fig:1}a) and at the order \( \alpha_s^4 \) (Fig. \ref{fig:1}b). They have pointed out that in most regions of phase space, the virtual gluons in Fig. \ref{fig:1}a are off their mass shells by amounts of order \( p_T \), where \( p_T \) refers to the large transverse momentum of charmonium state, and the contribution from this diagram is suppressed relative to the diagram in Fig. \ref{fig:1}b by a power of \( \alpha_s(p_T) \) when the spin-singlet S-wave charmonium \( \eta_c (^3S_0) \) is considered. Then, they have obtained the \( g \rightarrow \eta_c, J/\psi FF \) at \( \alpha_s(\mu = 2m_c)^2 \)-order. Authors have also calculated the FF for a gluon into J/\( \psi \) considering the Feynman diagram for the process \( g^* \rightarrow J/\psi gg \) (Fig. \ref{fig:1}b) to \( \alpha_s^3 \). They have not presented an analytical form for the \( D_{J/\psi}^{(z, \mu)} \) and, instead, the result is given in a two-dimensional integral form that must be evaluated numerically. In \cite{10},...
When the fragmenting gluon momentum $|k| \to \infty$, the definition \( \mu \) is equivalent to the light-cone definition \( \mu \). Therefore, we adopt the infinite momentum frame where the fragmentation parameter is defined as in \( \mu \). In Ref. \( \mu \), authors analysed the uncertainties induced by different definitions of the momentum fraction \( z \), including the covariant and non-covariant definitions and showed that the FFs corresponding to the light-cone definition of the fragmentation parameter \( z \) are equivalent to the ones in the infinite momentum frame of gluon. Instead, the non-covariant definition is usually used approximately

\[
 z = \frac{E^H}{E^g}. \tag{2}
\]

When the fragmenting gluon momentum $|k| \to \infty$, the definition \( \mu \) is equivalent to the light-cone definition \( \mu \). Therefore, we adopt the infinite momentum frame where the fragmentation parameter is defined as in \( \mu \).

In Ref. \( \mu \), authors analysed the uncertainties induced by different definitions of the momentum fraction \( z \), including the covariant and non-covariant definitions and showed that the FFs corresponding to the light-cone definition of the fragmentation parameter \( z \) are equivalent to the ones in the infinite momentum frame of gluon. Instead, the non-covariant definition \( \mu \) is used as an approximation unless $|k| \to \infty$.

With the large heavy quark mass, the relative motion of the heavy quark pair inside the charmonium is effectively nonrelativistic \( \mu \). For example, the squared relative velocity of the heavy quark pair in the charmonium rest frame is $v^2 \approx 0.22$ for the $J/\psi$ and $v^2 \approx 0.1$ for the $\Upsilon$ \( \mu \). The nonrelativistic assumption allows us to use a simple mesonic wave function which is the solution of the Schrödinger equation with a Coulomb potential \( \mu \). A typical simple mesonic wave function is given in \( \mu \) which is the nonrelativistic limit of the Bethe-Salpeter equation with the QCD kernel. Here, according to the Lepage-Brodsky’s approach \( \mu \) we also neglect the relative motion of the heavy quark pair inside the charmonium states and we assume, for simplicity, that the quark pair are emitted collinearly with each other and move along the Z-axes. This assumption allows us to estimate the nonrelativistic mesonic wave function as a delta function form (more detail can be found in \( \mu \)).

\[
\mu = \frac{|s_0,0,s_L|}{|t_0,0,t_L|} = \frac{|s_0,s'_L,s'_L|}{|t_0,t'_L,t'_L|} = \frac{|p_0,p_T,p_L|}{|\bar{p}_0,0,\bar{p}_L|}. \tag{3}
\]

Considering the definition of fragmentation parameter $z = E^H / E^g = \bar{P}_0 / p_0 \mu$, we also may write the parton energies in terms of the initial gluon energy $p_0$ as

\[
\mu = x_1 p_0 \quad \mu = x_2 p_0 \quad \mu = x_3 (1 - z) p_0 \quad \mu = x_4 (1 - z) p_0, \tag{4}
\]

where $x_1 = s_0 / \bar{P}_0$ and $x_2 = t_0 / \bar{P}_0$ are the meson energy fractions carried by the constituent quarks which the condition $x_1 + x_2 = 1$ holds for them. Following Refs. \( \mu \), in the nonrelativistic approximation we assume that the contribution of each constituent quark from the meson energy is proportional to its mass, i.e., $x_1 = m_1/M$ and $x_2 = m_2/M$ where $M = m_{J/\psi}$. Furthermore, we assume that the two gluon jets move almost in the same direction.

This assumption is justified due to the fact that the very high momentum of the initial gluon is predominantly carried in the forward direction. Due to momentum conservation, the total transverse momentum of the two gluon jets will be identical to the transverse momentum of the initial gluon. Therefore, we have $t'_\mu = s'_\mu = p_T / 2$. By this assumption one also has $x_3 = x_4 = 1/2$ in \( \mu \).

In the Suzuki’s model the fragmentation function $D_{\mu}^{J/\psi}(z,\mu)$ at the initial scale $\mu_0 = m_{J/\psi}$, is obtained by squaring the total amplitude and integrating over fi-
perturbation theory is expressed as

$$D_{g/J\psi}(z, \mu_0) = \frac{1}{1 + 2r_1} \sum_s |T_M|^2 \times \delta^3(\vec{P} + \vec{s}' + \vec{t}' - \vec{p}) d^3\vec{P} d^3\vec{s}' d^3\vec{t}'$$, (5)

where, $r_1$ is the spin of initial gluon and $T_M$ is the probability amplitude of the $J/\psi$ production. The amplitude $T_M$ involves the hard scattering amplitude $T_H$, which can be computed perturbatively from partonic subprocesses, and the process-independent distribution amplitude $\Phi_M$ which contains the bound state nonperturbative dynamic of outgoing meson, i.e.

$$T_M(\vec{P}, p, s', t') = \int \left[ dx_i \right] T_H(\vec{P}, p, s', t', x_i) \Phi_M(x_i, Q^2),$$ (6)

where, $\left[ dx_i \right] = dx_1 dx_2 \delta(1 - x_1 - x_2)$ and $x_i$'s are the momentum fractions carried by the constituent quarks. This scheme, introduced in [20, 24], is applied to absorb the soft behaviour of the bound state into the scattering amplitude $T_H$. The amplitude $T_H$ is, in essence, the partonic cross section to produce a heavy quark pair $c\bar{c}$ with certain quantum numbers that, in the old fashioned perturbation theory is expressed as

$$T_H = \frac{(4\pi\alpha_s(2m_c)^2)}{2\sqrt{2}P_0p_0s_0^0t_0^0} \frac{\Gamma}{(P_0 + t_0^0 + s_0^0 - p_0)}.$$ (7)

where, $\alpha_s$ is the strong coupling constant, $C_F = \sqrt{3}/12$ is the color factor and $\Gamma$ represents an appropriate combination of the quark propagators and the spinorial parts of the amplitude. It reads

$$\Gamma = G_1 G_2 \left\{ \bar{u}(s, r_3) \gamma_5(q + m_c)\gamma_i(t + m_c)\gamma_5 v(t, r_4) \right\}.$$ (8)

Here, $\gamma_i$'s are the gluon polarization vectors, $G_1 = 1/(q^2 - m_c^2) = 1/(2s')$ and $G_2 = 1/(k^2 - m_c^2) = 1/(2t'.t)$ are proportional to the quark propagators. We put the dot products of the relevant four-vectors in the following form

$$t.t' = s.s' = \frac{zm_c}{4M(1 - z)} \frac{p_T^2 + M(1 - z)m_c}{4z},$$ (9)

In [20]. $\Phi_M$ is the process-independent probability amplitude to find quarks co-linear up to a scale $Q^2$ in the mesonic bound state, so that by working in the infinite-momentum frame it can be estimated as a delta function. Therefore, the distribution amplitude for a S-wave heavy meson with neglecting the Fermi motion, reads [20, 22]

$$\Phi_M \approx \frac{f_M}{2\sqrt{3}} \delta(x_1 - \frac{m_c}{M}),$$ (10)

where $M$ is the meson decay mass and $f_M = \sqrt{12/M} |\Psi(0)|$ is the meson decay constant which is related to the nonrelativistic mesonic S-wave function $\Psi(0)$ at the origin.

Substituting Eqs. (6), (7) and (10) in (5) and carrying out the necessary integrations, the fragmentation function reads

$$D_{g/J\psi}(z, \mu_0) = \frac{2}{3} \left( \alpha_s(4\pi)^3 F_M C_F m_c^2 \right)^2 \times \int \frac{1}{(P_0 p_0 s_0^0 t_0^0)}(P_0 + s_0^0 + t_0^0 - p_0)^2 d^3\vec{P} d^3\vec{s}' d^3\vec{t}'.$$ (11)

To obtain an analytical form of the fragmentation function for gluon to split into the S-wave charmonium (i.e. $\eta_c, J/\psi$), we apply the scenario introduced in [20]. According to this scenario if $v(t)$ and $\bar{u}(s)$ are the Dirac spinors of the quarks forming the charmonium bound states, in the nonrelativistic approximation the projection operator is defined as

$$\Lambda_{s.s, s}(t) = v(t)u(s) \propto (\gamma + m_c)\Pi_{s.s, s},$$ (12)

where $\Pi_{s.s}$ is the appropriate spin projection operator; $\Pi_{00} = \gamma_5$ for pseudoscalar state ($\eta_c$) and $\Pi_{s.s} = \gamma_5$ for vector state ($J/\psi$). The spin content of the polarized meson is then given by either $\gamma_5$ or $\gamma'$ as could well be expected. This operator is convenient for our assumption in which we ignore the Fermi motion, so that the constituent quarks will fly together in parallel. Therefore, the spinorial part of the amplitude for formation of the vector charmonium state $J/\psi$, which we denote by $V$, may be presented in the following form

$$\Gamma^V \propto G_1 G_2 \left\{ (\gamma + m_c)\gamma_5 (q + m_c)\gamma_i (\gamma + m_c)\gamma_5 \right\},$$ (13)

where $q = s + s'$ and $k = t + t'$ are the energy-momenta of the virtual intermediate quarks, $\epsilon$ is the polarization four-vector of the meson $J/\psi$ which may be in a longitudinal state $\epsilon^{(L)} = (t', P, \lambda = 0)$ or a transverse state $\epsilon^{(T)} = (t, P, \lambda = \pm 1)$. These components satisfy the relations; $\epsilon(P, \lambda), P = 0 \Rightarrow \epsilon(T), P = 0 = \epsilon(L) \times P$ and $\epsilon(P, \lambda), \epsilon * (P, \lambda') = -\delta_{\lambda, \lambda'}$. Therefore, for a vector charmonium with the four-moment $P^n = [P_0, 0, P_L]$, the polarization four-vector is expressed as

$$\epsilon^{(L)} = \frac{1}{M} (P_0, 0, 0, P_L),$$

$$\epsilon^{(T)} = \frac{1}{\sqrt{2}} (0, \mp 1, -i, 0),$$ (14)

where $P_L = s_L + t_L$ and $P_0 = s_0 + t_0$.

Now to obtain an analytical form of the $J/\psi$ FF, in (14) we perform a sum over the colors and the spins of gluons. Then the amplitude squared $\Gamma^V\Gamma^V$ reads

$$\sum_s \Gamma^V \Gamma^V = 4G_1^2 G_2^2 T \left[ (\gamma + m_c)\gamma_5 (q + m_c)\gamma_5 (\gamma + m_c) \right] \times (\gamma + m_c)\gamma_i (q + m_c)\gamma_5 \gamma_i (\gamma + m_c).$$ (15)

Using the traditional trace technique, the trace may be expressed as the dot products of four-vectors. Here, we
put the dot products of the relevant four-vectors in the following forms:

\[ t'.s' = 0, \]
\[ p.e_T = \frac{p.T}{\sqrt{2}}(-1 + i), \]
\[ p.e_L = -\frac{M}{2z} + \frac{z}{2M}p_T^2, \]
\[ p.s = p.t = \frac{m_c^2}{z} + \frac{z}{4}p_T^2, \]
\[ p.t' = p.s' = \frac{z^2}{4(1-z)p_T^2}. \]

To proceed we need to specify the phase space integrations in \((11)\). Note that, the fragmentation function for a vector charmonium \(J/\psi\) is the sum of the longitudinal and twice the transverse components, i.e. \(D_{g\to J/\psi}(z, \mu_0) = 2D_g^T + D_g^L\). Finally, putting all in \((11)\) and by assuming \(M = 2m_c\) in the nonrelativistic limit, we obtain the longitudinal and the transverse components of the \(g \to J/\psi\) FF, as

\[
D_{g\to J/\psi}^T(z, \mu_0) = \frac{8N_1 z\alpha_s^3}{g(z, \langle p_T^2 \rangle)} \left[ -16 \frac{z^2}{z^2} m_c^6 \right. \\
- \frac{8}{z(1-z)}(2z^3 + 4z^2 + 3z - 4)m_c^4 p_T^2 \\
\left. + \frac{1}{(1-z)^3} \left( z(17z^2 - 25z + 8)m_c^4 p_T^2 - z^4 p_T^6 \right) \right],
\]

and

\[
D_{g\to J/\psi}^L(z, \mu_0) = \frac{4N_1 z\alpha_s^3}{g(z, \langle p_T^2 \rangle)} \left[ -32 \frac{z^2}{z^2} m_c^6 \\
+ \frac{16}{1-z} (3z^2 + 2z + 2)m_c^4 p_T^2 \\
\right. \\
\left. \frac{1}{(1-z)^3} \left( 2z^2(-4z^2 - 7z + 11)m_c^4 p_T^2 + 3z^4 p_T^6 \right) \right].
\]

Note that, the fragmentation function for a vector charmonium \(J/\psi\) is the sum of the longitudinal and twice the transverse components, i.e. \(D_{g\to J/\psi}(z, \mu_0) = 2D_g^T + D_g^L\). Finally, we point out that to impose the effect of quarkonium spin into the calculation, a second scenario is defined in \([22, 27]\), where in the nonrelativistic approximation the spin projection operator is expressed as

\[
\Lambda_{S,S_z}(\vec{P}) = \frac{f_M}{\sqrt{48}}(\vec{P} + M)\Pi_{S,S_z}, \tag{23}
\]

where \(f_M\) is the meson decay constant and \(M\) and \(\vec{P}\) are the mass and the four-momentum of meson bound state, respectively. In the nonrelativistic limit \((\vec{P} = 2\vec{p}, M = 2m_c)\), these two scenarios \([12, 23]\) are the same and, in conclusion, the sum of transverse and longitudinal polarisations of the \(J/\psi\) should be identical.

### B. \(\eta_c\) in gluon fragmentation

Following Ref. \([2]\), the fragmentation function for a gluon to split into the pseudoscalar S-wave charmonium \(\eta_c\) can be calculated by considering Fig. \((1a)\). To derive
an analytical result of the $g \rightarrow \eta_c$ FF we consider the Feynman diagram shown in Fig. \ref{fig:diagram} where a gluon forms a bound state $c\bar{c}$ with a gluon produced through a single $c$-quark. The four-momenta of meson and partons are also labelled. According to our previous assumption the meson and its constituent quarks move along the $Z$-axes (fragmentation axes). Then one can set the relevant four-momenta

$$p_\mu = [p_0, \mathbf{p}_T, \mathbf{p}_L], \quad k_\mu = [k_0, \mathbf{k}_T, \mathbf{k}_L].$$

Next we consider the phase space integrations \eqref{eq:phase_space}. Following our early discussion in this section, we propose a delta function as \eqref{eq:delta_function} for the amplitude $\Phi_M$. Using the perturbation theory, the amplitude $T_H$ is written in the following form

$$T_H = \frac{4\pi\alpha_s(2m_c)m_c^2C_F}{2\sqrt{2}P_0k_0} \Gamma \frac{\bar{P}}{P_0 + k_0 - p_0},$$

where $\Gamma$ represents the spinorial parts of the amplitude as

$$\Gamma = G \{ \bar{u}(k', r_2)v_\gamma(k)(q' + m_c)\phi_\gamma(p)v(p', r_1) \}.$$

Here, $G = 1/(q^2 - m_c^2)$ is proportional to the quark propagator and $C_F = 1/(2\sqrt{3})$ is the color factor.

Putting all in \eqref{eq:fragmentation_function}, the fragmentation function reads

$$D_g^\eta_c(z, \mu_0) = \frac{1}{6}(\pi\alpha_s f_M^2C_F m_c^2)^2 \times \left( 1 + 2 \right) \sum \frac{\Gamma_{\mu}^{3}}{p_0k_0} \left( \frac{\bar{P}}{P_0} \frac{\bar{P}}{P_0 + k_0 - p_0} \right)^2 d^3\bar{P}.$$

Considering the scenario introduced in previous section \ref{sec:scenario}, where the spin projection operator for a pseudoscalar charmonium state $\eta_c$ is $\Pi_{00} = \gamma_5$, the spinorial part of the amplitude \eqref{eq:spinorial_part} is presented in the following form

$$\Gamma^{P} \propto G \{(q' + m_c)\bar{\gamma}_5 \phi_\gamma(k)(q' + m_c)\phi_\gamma(p) \}.$$

By performing a sum over the colors and the spins of gluons, the amplitude squared reads

$$\sum_s \Gamma^{P}\bar{\Gamma}^{P} = 128G^2m_c^2 \left\{ 2m_c^2 + 2k.k' + (k+k') \right\}.$$  \hspace{1cm} \text{(30)}$$

Next we consider the phase space integrations \eqref{eq:phase_space}. Following our early approach, we have

$$\int d^3\bar{P} \delta^3(\bar{P} + k - p) \frac{P_0}{P_0(P_0 + k_0 - p_0)^2} = \frac{P_0}{(M^2 + 2p.k)^2},$$

and

$$\int F(z, p_T^2) d^3k = m_c^2k_0 F(z, \langle p_T^2 \rangle).$$

In order to get the correct result for the fragmentation function of the process $g \rightarrow \eta_c$, it is necessary to consider a second diagram that can be obtained from Fig. \ref{fig:diagram} by interchanging the two vertices where the gluons attached to the heavy quark lines.

In conclusion, in the referred scenario the fragmentation function of the process $g \rightarrow \eta_c$ is expressed as

$$D_{g \rightarrow \eta_c}(z, \mu_0) = \frac{N_2\alpha_s^2 z}{g(z, \langle p_T^2 \rangle)} (192m_c) \times [2m_c + \frac{zp_T^2}{M(1-z)} + \frac{M(1-z)}{z}] \hspace{1cm} \text{(33)}$$

where $N_2 = (\pi m_c^2 f_M^2 C_F)^2/864$, and

$$g(z, \langle p_T^2 \rangle) = \left( \frac{M^2}{1-z} + \frac{z^2p_T^2}{1-z} \right)^2 \left( \frac{z^2p_T^2 + M^2(1-z)^2}{Mz(1-z)} \right).$$

### III. RESULTS AND DISCUSSION

We are now in a position to present our phenomenological predictions for the gluon fragmentation into the $\eta_c$ and $J/\psi$, by performing a numerical analysis. In general, the fragmentation function $D_g^\eta_c(z, \mu)$ depends on the factorization scale $\mu$. Here, we have set the scale in the FF and in the running coupling constant $\alpha_s(\mu)$ to $\mu = 2m_c$ which is the minimum value of the invariant mass of the fragmenting gluon. Therefore, the functions \eqref{eq:fragmentation_function} and \eqref{eq:spinorial_part} should be regarded as models for the $g \rightarrow \eta_c, J/\psi$ FFs at the initial scale $\mu_0 = 2m_c$. For values of $\mu$ much larger than $\mu_0$, the initial FFs should be evolved from the
scale $\mu_0$ to the higher scale $\mu$ using the Altarelli-Parisi equations \cite{28,29}

$$\mu \frac{\partial}{\partial \mu} D_{i \rightarrow H}(z, \mu) = \sum_j \int_z^1 \frac{dy}{y} P_{i ightarrow j}(z/y, \mu) D_{j ightarrow H}(y, \mu),$$ \hspace{1cm} (35)

where $P_{i ightarrow j}(x, \mu)$ are the Altarelli-Parisi functions for the splitting of the parton of type $i$ into a parton of type $j$ with momentum fraction $x$. The only boundary condition on this evolution equation is the fragmentation function $D_{i \rightarrow H}(z, \mu_0)$ at the scale $\mu_0 = 2m_c$.

For numerical results, we take $m_c = 1.5$ GeV, $m_{J/\psi} = 3096.9$ MeV, $m_{\eta_c} = 2983.6$ MeV, $\alpha_s(2m_c) = 0.26$ and $f_M(c\bar{c}) = 0.48$ GeV \cite{30}.

In Fig. 5, our prediction for the $g \rightarrow \eta_c$ FF \cite{33} by considering two values of the gluon transverse momentum ($p_T = 10, 15$ GeV) is shown. It shows that the fragmentation function distribution relies on the momentum $p_T$ of the initial gluon. In Fig. 6, the behaviour of the $g \rightarrow J/\psi$ FF is studied. Here, $D^{J/\psi}_g(z, \mu_0)$ is the convenient summation of the longitudinal and transverse fragmentation functions as $D^{J/\psi}_g(z, \mu_0) = 2D^L_{J/\psi} + D^T_{J/\psi}$, see Eqs. (20) \cite{21}. Our result shown in Fig. 6 is in acceptable agreement with the result presented in \cite{2} where $B(2m_c) = 3.2 \times 10^{-6}$.

Our results may be directly applied to the S-wave bottomonium states $\Upsilon(1S\bar{1})$ and $\eta_b(1S_0)$, except that $m_c$ is replaced by $m_b = 4.5$ GeV and the decay constant $f_M(b\bar{b}) = 0.33$ GeV \cite{32} is the appropriate constant for the bottomonium states. Since the b-quark is heavier than the c-quark, we expect that the peaks of the fragmentation functions shift significantly toward higher values of $z$. Our results for the $g \rightarrow \eta_c, J/\psi$ FFs will be checked by the comparison between the theoretical predictions and the experimental measurements of the heavy meson cross sections at the LHC.

**IV. CONCLUSION**

Understanding hadronization, the process by which a parton evolves into a hadron, is complicated by its intrinsically nonperturbative nature. In hadron colliders, at sufficiently large transverse momentum of the heavy quarkonium production the direct production schemes
are normally suppressed while the fragmentation mechanism becomes dominant. The fragmentation refers to the process of a parton with high transverse momentum which subsequently decays into the expected hadron \cite{2}. Beside the phenomenological approaches, it is well-known that the fragmentation function which describes this process can be calculated using perturbative QCD. In this paper we, for the first time, gave out an analytical form for the leading color-singlet contribution to the fragmentation function for a gluon to split into the vector and pseudoscaler S-wave charmonia (J/ψ, ηc) at the initial scale \( \mu = 2m_c \). We used a different model in getting them from the Braaten’s model applied in other literatures, see Refs. \cite{2, 14}. Our results depend on the transverse momentum of the initial gluon and shows a simple analytical form whereas in the Braaten’s model, the integrations over all freedom degrees are performed and due to the lengthy and cumbersome expression of the FFs the results are presented as the two-dimensional integrals that must be evaluated numerically. Since the transverse momentum dependent FFs show up explicitly in semi-inclusive cross sections, therefore in the QCD corrections the inclusion of these dependent FFs will be necessary. Our result for the \( g \to J/\psi \) FF is in acceptable consistency with the numerical result presented in Ref. \cite{16}, when one uses the normal definition of the fragmentation parameter \cite{2}. We also found that the fragmentation probability of a high energy gluon splitting into J/ψ is about \( 10^{-6} \).
