Abstract

We evaluate differential distributions for the four-body \( pp \rightarrow ppK^+K^- \) reaction at high energies which constitutes an irreducible background to three-body processes \( pp \rightarrow ppM \), where \( M = \phi, f_2(1275), f_0(1500), f'_2(1525), \chi_{c0} \). We consider central diffractive contribution mediated by Pomeron and Reggeon exchanges as well as completely new mechanism of emission of kaons from the proton lines. We include absorption effects due to proton-proton interaction and kaon-kaon rescattering. We compare our results with measured cross sections for the CERN ISR experiment. We make predictions for future experiments at RHIC, Tevatron and LHC. Differential distributions in invariant two-kaon mass, kaon rapidities and transverse momenta of kaons are presented. Two-dimensional distribution in \( (y_{K^+}, y_{K^-}) \) is particularly interesting. The higher the incident energy, the higher preference for the same-hemisphere emission of kaons. We find that the kaons from the new mechanism of emission directly from proton lines are produced rather forward and backward but the corresponding cross section is rather small. The processes considered here constitute a sizeable contribution to the total proton-proton cross section as well as to kaon inclusive cross section.

We consider a measurement of exclusive production of scalar \( \chi_{c0} \) meson in the proton-proton collisions via \( \chi_{c0} \rightarrow K^+K^- \) decay. The corresponding amplitude for exclusive central diffractive \( \chi_{c0} \) meson production is calculated within the \( k_t \)-factorization approach. The influence of kinematical cuts on the signal-to-background ratio is discussed.

Keywords: Diffractive processes, \( KK \) continuum, \( \chi_{c}(0^+) \rightarrow K^+K^- \) decay

I. INTRODUCTION

The exclusive $pp \rightarrow ppK^+K^-$ reaction was studied only at low energy \cite{1,2}. Here the dominant mechanisms are exclusive $a_0(980)$ and $f_0(980)$ production \cite{1} or excitation of nucleon and $\Lambda$ resonances \cite{2}. The main aim of this paper is to discuss mechanisms of exclusive $K^+K^-$ production in hadron-hadron collisions at high energies. Processes of central exclusive production became recently a very active field of research (see e.g. Ref. \cite{5} and references therein). Although the attention is paid mainly to high-$p_t$ processes that can be used for new physics searches (exclusive Higgs, $\gamma\gamma$ interactions, etc.), measurements of low-$p_t$ signals are also very important as they can help to constrain models of the backgrounds for the former ones. The $pp \rightarrow ppK^+K^-$ reaction is a natural background for exclusive production of resonances decaying into $K^+K^-$ channel, such as: $\phi$, $f_2(1270)$, $f_0(1500)$, $f_2'(1525)$, $\chi_{c0}$. The expected non-resonant background can be modeled using a ”non-perturbative” framework, mediated by Pomeron-Pomeron fusion with an intermediate off-shell pion/kaon exchanged between the final-state particles. The two-pion background to exclusive production of $f_0(1500)$ meson was discussed in Ref. \cite{3}. In Refs.\cite{3,4} we have studied production of $\pi^+\pi^-$ pairs for low and high energies. Here we wish to present similar analysis for $K^+K^-$ production at high energies. The dominant mechanism of the $pp \rightarrow pp\pi^+\pi^-$, $pp \rightarrow ppK^+K^-$ reactions at high energies is relatively simple compared to that of the $pp \rightarrow nn\pi^+\pi^-$ \cite{7} or $pp \rightarrow pp\pi^0\pi^0$ processes. In Ref. \cite{7} a possible measurement of the exclusive $\pi^+\pi^-$ production at the LHC with tagged forward protons has been studied.

A study of the centrally produced $\pi^+\pi^-$ and $K^+K^-$ channels in $pp$ collisions has been performed experimentally at an incident beam momenta of 300 GeV/c ($\sqrt{s} = 23.8$ GeV) \cite{9} and 450 GeV/c ($\sqrt{s} = 29.1$ GeV) \cite{10}. In the latter paper a study has been performed of resonance production rate as a function of the difference in the transverse momentum vectors ($dP_T$) between the particles exchanged from vertices. An analysis of the $dP_T$ dependence of the four-momentum transfer behavior shows that the $\rho^0(770)$, $\phi(1020)$, $f_2(1270)$ and $f_2'(1525)$ are suppressed at small $dP_T$ in contrast to the $f_0(980)$, $f_0(1500)$ and $f_0(1710)$. Different distributions are observed in the azimuthal angle (defined as the angle between the $p_t$ vectors of the two outgoing protons) for the different resonances (see \cite{10}). The mass spectrum of the exclusive $K^+K^-$ system at the CERN Intersecting Storage Rings (ISR) is shown e.g. in Ref.\cite{11} at $\sqrt{s} = 63$ GeV and in Ref.\cite{12} at $\sqrt{s} = 62$ GeV (this is the highest energy at which normalized experimental data exist).

Recently there was interest in central exclusive production of $P$-wave quarkonia (Refs. \cite{13,17}) where the QCD mechanism is similar to the exclusive production of the Higgs boson. Furthermore, the $\chi_{c(0,2)}$ states are expected to annihilate via two-gluon processes into light mesons in particular into $K^+K^-$. Also some glueball candidates \cite{18} can be searched for in this channel.

The cross section for central exclusive production of $\chi_c$ mesons has been measured recently in proton-antiproton collisions at the Tevatron \cite{19}. In this experiment $\chi_c$ mesons are identified via decay to the $J/\psi + \gamma$ with $J/\psi \rightarrow \mu^+\mu^-$ channel. At the Tevatron the experimental invariant mass resolution was not sufficient to distinguish between scalar, axial and tensor $\chi_c$. While the branching fractions to this channel for axial and tensor mesons are large \cite{20} ($B = (34.4 \pm 1.5)\%$ and $B = (19.5 \pm 0.8)\%$, respectively) the branching fraction for the scalar meson is very small $B = (1.16 \pm 0.08)\%$ \cite{20}. Theoretical calculations have shown \cite{15} that the cross section for exclusive $\chi_{c0}$ production obtained within the $k_t$-factorization is much bigger than that for $\chi_{c1}$ and $\chi_{c2}$. As a consequence, all $\chi_c$ mesons give similar
possibility to measure $\chi_{c0}$ is smaller to the signal. The measurement of exclusive production of $\chi_{c0}$ CEP via two-body decay channels is of special interest for studying the dynamics of heavy quarkonia.

The scalar $\chi_{c0}$ meson decays into several two-body (e.g. $\pi\pi$, $K^+K^-$, $p\bar{p}$) and four-body final states (e.g. $\pi^+\pi^-\pi^+\pi^-$, $\pi^+\pi^-K^+K^-$). The observation of $\chi_{c0}$ CEP via two-body decay channels is of special interest for studying the dynamics of heavy quarkonia. The measurement of exclusive production of $\chi_{c0}$ meson in proton-(anti)proton collisions via $\chi_{c0} \rightarrow \pi^+\pi^-$ decay has been already discussed in Ref. [21]. In the present paper we analyze a possibility to measure $\chi_{c0}$ via its decay to $K^+K^-$ channel. The branching fraction to this channel is relatively large $B(\chi_{c0} \rightarrow K^+K^-) = (0.61 \pm 0.035)\%$ [20]. In addition, the axial $\chi_{c1}$ does not decay to the $KK$ channel and the branching ratio for the $\chi_{c2}$ decay into two kaons is smaller $B(\chi_{c2} \rightarrow K^+K^-) = (0.109 \pm 0.008)\%$ [20]. A much smaller cross section for $\chi_{c2}$ production as obtained from theoretical calculation means that only $\chi_{c0}$ will contribute to the signal.

Exclusive charmonium decays can be also studied in $e^+e^-$ colliders. Here the $\chi_{cJ}$ states are copiously produced in the radiative decays $\psi(2S) \rightarrow \gamma\chi_{cJ}$ [20]. Recently the BESIII Collaboration performed a measurement of the hadronic decays of the three $\chi_{cJ}$ states to $p\bar{p}K^+K^-$ ($p\bar{K}^+\Lambda(1520)$, $\Lambda(1520)\bar{\Lambda}(1520)$ and $\phi\bar{p}p$) [22]. In the present paper we discuss a possibility to measure $\chi_{c0}$ in the $K^+K^-$ channel. Here, continuum backgrounds are expected to be larger than in the $e^+e^-$ collisions. This will discussed in the present paper.

II. CENTRAL DIFFRACTIVE CONTRIBUTION

A. The $KN$ scattering

In order to fix parameters of our double Pomeron exchange (DPE) model we consider first elastic $KN$ scattering. The forward amplitudes $M_{KN}(s, t = 0)$ of the elastic scatterings are written in terms of the Regge exchanges

$$M_{K^+p \rightarrow K^+p}(s, 0) = A_P(s, 0) + A_2(s, 0) + A_3(s, 0) \mp A_\omega(s, 0) \mp A_\rho(s, 0),$$
$$M_{K^+n \rightarrow K^+n}(s, 0) = A_P(s, 0) + A_2(s, 0) - A_3(s, 0) \mp A_\omega(s, 0) \pm A_\rho(s, 0).$$

The optical theorem relates the total cross section for the scattering of a pair of hadrons to the amplitude for elastic scattering: $\text{Im} M_{el}(s, t = 0) \sim s \sigma_{tot}(s)$. When the centre-of-mass energy $\sqrt{s}$ is large the elastic $KN$ scattering amplitude is a sum of the terms:

$$A_i(s, t) = \eta_i s C_i^{KN} \left( \frac{s}{s_0} \right)^{\alpha_i(t)-1} \exp \left( \frac{B_i^{KN} t}{2} \right),$$

where $i = P, f_2, a_2, \omega$ and $\rho$. The energy scale $s_0$ is fixed at $s_0 = 1$ GeV$^2$. The values of coupling constants ($C_i^{KN}$) are taken from the Donnachie-Landshoff analysis of the total cross section in several hadronic reactions [23]. The parameters of Regge linear trajectories ($\alpha_i(t) = \alpha_i(0) + \alpha_i^t t$) and signature factors ($\eta_i$) used in the present calculations are listed in Table I. The slope of the elastic $KN$ scattering can be written as

$$B(s) = B_{KN}^i + 2\alpha_i^t \ln \left( \frac{s}{s_0} \right)$$

and only the $B_{KN}^i$ parameters are adjusted to the existing experimental data for the elastic $KN$ scattering.
The differential elastic cross section is expressed with the help of the elastic scattering amplitude as usually:

\[
\frac{d\sigma_{el}}{dt} = \frac{1}{16\pi s^2} |M_{KN}(s,t)|^2.
\]  

(2.4)

The differential distributions \(d\sigma_{el}/dt\) for both \(K^+p\) and \(K^-p\) elastic scattering for three incident-beam momenta of \(P_{lab} = 5\) GeV, \(P_{lab} = 50\) GeV and \(P_{lab} = 200\) GeV are shown in Fig.1. With the slope parameters, as in Ref. \[6\], \(B_{KN}^{KN} = B_{KN}^{\pi N} = 5.5\) GeV\(^{-2}\), \(B_{RN}^{KN} = B_{RN}^{\pi N} = 4\) GeV\(^{-2}\) for Pomeron and Reggeon exchanges, a rather good description of experimental \(d\sigma_{el}/dt\) is achieved. The exception is the low energy \(K^+p\) scattering. Here \(\Lambda\) baryon exchange is a possible mechanism in addition to Pomeron and Reggeon exchanges.

We nicely describe the existing experimental data for elastic \(KN\) scattering for \(\sqrt{s} > 3\) GeV, as can be seen from Fig.2. In the Regge approach, high energy cross section is dominated by Pomeron exchange (dashed lines). The Reggeon exchanges dominate in the resonance region (dash-dotted lines). While the total cross section is just a sum of the Pomeron and Reggeon terms, the elastic cross section have the interference term (long-dashed lines).
TABLE I: Parameters of Pomeron and Reggeon exchanges determined from elastic and total cross sections used in the present calculations.

| $i$ | $\eta_i$ | $\alpha_i(t)$ | $C_i^{NN}$ (mb) | $C_i^{KN}$ (mb) | $C_i^{KK}$ (mb) |
|-----|----------|---------------|----------------|----------------|----------------|
| P   | $i$      | $1.0808 + (0.25 \text{ GeV}^{-2}) t$ | 21.7 | 11.82 | $\simeq 6.438$ |
| $f_2$ | $(-0.860895 + i)$ | $0.5475 + (0.93 \text{ GeV}^{-2}) t$ | 75.4875 | 15.67 | $\simeq 3.253$ |
| $\rho$ | $(-1.16158 - i)$ | $0.5475 + (0.93 \text{ GeV}^{-2}) t$ | 1.0925 | 2.05 | $\simeq 3.847$ |
| $a_2$ | $(-0.860895 + i)$ | $0.5475 + (0.93 \text{ GeV}^{-2}) t$ | 1.7475 | 1.585 | $\simeq 1.438$ |
| $\omega$ | $(-1.16158 - i)$ | $0.5475 + (0.93 \text{ GeV}^{-2}) t$ | 20.0625 | 7.055 | $\simeq 2.481$ |

In order to exclude low energy regions the $M_{KN}(s, t)$ elastic scattering amplitudes are corrected by purely phenomenological smooth cut-off correction factor (as in Ref. [6]).

FIG. 2: The integrated cross section for the $KN$ total and elastic scattering. The experimental data are taken from particle data book [20]. The lines are explained in the main text. Our model sufficiently well describes the $KN$ data and includes absorption effects due to kaon-nucleon rescatterings in an effective way. This has a clear advantage for applications to the $pp \rightarrow ppK^+K^-$ reaction where the $KN$ absorption effects do not need to be included explicitly. Having fixed the parameters we can proceed to our four-body $pp \rightarrow ppK^+K^-$ reaction.

B. Central diffractive production of $K^+K^-$

The dominant mechanism of the exclusive production of $K^+K^-$ pairs at high energies is sketched in Fig. 3. The formalism used in the calculation of the amplitude is explained in
FIG. 3: The central diffractive mechanism of exclusive production of $K^+K^-$ pairs including the absorptive corrections due to proton-proton interactions as well as kaon-kaon rescattering.

detail elsewhere for the $\pi^+\pi^-$ production [6, 21] and here only main aspects are discussed. The full amplitude for the process $pp \rightarrow pK^+K^-p$ (with four-momenta $p_a + p_b \rightarrow p_1 + p_3 + p_4 + p_2$, respectively) is a sum of the Born and rescattering amplitudes

$$
M_{pp \rightarrow ppKK} = M^{Born} + M^{pp-rescatt.} + M^{KK-rescatt.}.
$$

The Born amplitude can be written as

$$
M^{Born} = M_{13}(s_{13}, t_1) F_K(\hat{t}) \frac{1}{\hat{t} - m_K^2} F_K(\hat{u}) M_{24}(s_{24}, t_2) + M_{14}(s_{14}, t_1) F_K(\hat{u}) \frac{1}{\hat{u} - m_K^2} F_K(\hat{t}) M_{23}(s_{23}, t_2),
$$

where $M_{ik}(s_{ik}, t_i)$ denotes "interaction" between forward proton ($i = 1$) or backward proton ($i = 2$) and one of the two kaons ($k = 3$ for $K^+$, $k = 4$ for $K^-$). The energy dependence of the $KN$ elastic amplitudes is parameterized in terms of Pomeron and $f_2, a_2, \omega$ and $\rho$ Reggeon exchanges as explained in section II A. The Donnachie-Landshoff parametrization is used only above resonance regions for the $KN$ subsystem energy $\sqrt{s_{ik}} > 2 - 3$ GeV. In order to exclude resonance regions the $M_{ik}$ terms are corrected by a purely phenomenological smooth cut-off correction factors which in practice modify the cross section only at large rapidities [6].

The kaon exchange as a meson exchange is a correct description at rather low energies. At higher energies a kaon reggeization is required [21]. This is done by the following replacement:

$$
\frac{1}{\hat{t}/\hat{u} - m_K^2} \rightarrow \beta_M(\hat{s}) \frac{1}{\hat{t}/\hat{u} - m_K^2} + \beta_R(\hat{s}) \mathcal{P}_K(\hat{t}/\hat{u}, \hat{s}),
$$

where we have introduced the kaon Regge propagator $\mathcal{P}_K(\hat{t}/\hat{u}, \hat{s}) = \mathcal{P}_\pi(\hat{t}/\hat{u}, \hat{s})$ (see Ref. [21, 25]). Above we have written $\hat{s}, \hat{t}, \hat{u}$ to stress that these are quantities for a subprocess rather than for a full reaction. $\beta_M(\hat{s})$ and $\beta_R(\hat{s})$ are the phenomenological functions which role is to interpolate between meson and Reggeon exchange. Here, as in Ref. [21], we parametrize them as: $\beta_M(\hat{s}) = \exp\left(-\left(\hat{s} - 4m_K^2\right)/\Lambda_{int}^2\right)$, $\beta_R(\hat{s}) = 1 - \beta_M(\hat{s})$. The parameter $\Lambda_{int}$ can be fitted to experimental data. From our general experience in hadronic physics we expect it to be about $\Lambda_{int} \sim 1 - 2$ GeV.
The form factors, $F(\hat{t}/\hat{u})$, correct for the off-shellness of the intermediate kaons in the middle of the diagrams shown in Fig. 3. In the following they are parameterized as

$$F_K(\hat{t}/\hat{u}) = \exp\left(\frac{\hat{t}/\hat{u} - m_{K}^2}{\Lambda_{\text{off}}^2}\right), \quad (2.8)$$

where the parameter $\Lambda_{\text{off}}$ is not known in general but, in principle, could be fitted to the normalized experimental data. How to extract $\Lambda_{\text{off}}$ will be discussed in the result section.

The absorptive corrections to the Born amplitude due to $pp$-interactions were taken into account in [21] as

$$\mathcal{M}_{pp-\text{rescatt.}} = \frac{i}{8\pi^2 s} \int d^2k_t A_{pp-pp}(s, k_t^2) \mathcal{M}_{\text{Born}}(p_a^* - p_{1,t}, p_b^* - p_{2,t}), \quad (2.9)$$

where $p_a^* = p_a - k_t$, $p_b^* = p_b + k_t$ and $k_t$ is the transverse momentum exchanged in the blob.

The formula presented so far do not include $\pi\pi, KK \rightarrow KK$ rescatterings. The pion-pion interaction at high energies was studied e.g. in Refs. [26, 27]. In full analogy to those works at the higher energies one can include the $\pi\pi, KK \rightarrow KK$ rescattering for our four-body reaction by replacing the normal (or reggeized) pion/kaon propagators (including vertex form factors).

The $KK \rightarrow KK$ subprocess amplitude for $t$ and $u$ diagrams in Fig. 3 is written in the high-energy approximation

$$\frac{F_K^2(\hat{t})}{\hat{t} - m_{K}^2} \rightarrow \frac{i}{16\pi^2 s} \int d^2k_t F_K^2(\hat{t}_1) M_{K^+K^-\rightarrow K^+K^-}(\hat{s}, \hat{t}_2),$$

$$\frac{F_K^2(\hat{u})}{\hat{u} - m_{K}^2} \rightarrow \frac{i}{16\pi^2 s} \int d^2k_t F_K^2(\hat{u}_1) M_{K^-K^+\rightarrow K^-K^+}(\hat{s}, \hat{u}_2). \quad (2.10)$$

Here the integration is over momentum in the loop (see [21]). The quantities $\hat{t}_1, \hat{u}_1$ and $\hat{t}_2, \hat{u}_2$ are four-momenta squared of the exchanged objects in the first and in the second step of the rescattering process. Other details are explained in [26].

The elastic amplitudes in the $KK \rightarrow KK$ subprocesses are written as

$$M_{KK\rightarrow KK}(\hat{s}, \hat{t}_2/\hat{u}_2) = \beta_M(\hat{s}) A^{V-\text{exch.}}_{KK\rightarrow KK}(\hat{t}_2/\hat{u}_2) + \beta'_R(\hat{s}) A_{KK\rightarrow KK}^{\text{Regge}}(\hat{s}, \hat{t}_2/\hat{u}_2), \quad (2.11)$$

for vector meson ($V = \rho, \omega, \phi$) exchanges and $\beta'_M(\hat{s}) = \exp(-(\hat{s} - 4m_{K}^2)/\Delta\hat{s})$, $\beta'_R(\hat{s}) = 1 - \beta'_M(\hat{s})$, $\Delta\hat{s} = 9 \text{ GeV}^2$.

The Regge-type interaction which includes Pomeron and Reggeon ($f_2, a_2, \rho$ and $\omega$) exchanges applies at higher energies:

$$A^{\text{Regge}}_{K^+K^-\rightarrow K^+K^-}(\hat{s}, \hat{t}_2) = \eta_\rho \hat{s} C_{iK}^{KK} \left(\frac{\hat{s}}{\hat{s}_0}\right)^{\alpha_i(\hat{t}_2)-1} \exp\left(\frac{B^i_{KK}(\hat{t}_2)}{2}\right),$$

$$A^{\text{Regge}}_{K^-K^+\rightarrow K^-K^+}(\hat{s}, \hat{u}_2) = \eta_\rho \hat{s} C_{iK}^{KK} \left(\frac{\hat{s}}{\hat{s}_0}\right)^{\alpha_i(\hat{u}_2)-1} \exp\left(\frac{B^i_{KK}(\hat{u}_2)}{2}\right), \quad (2.12)$$

where the scale parameter $\hat{s}_0$ is taken as 1 GeV$^2$ and the $C_{iK}^{KK}$ coupling constants can be evaluated assuming Regge factorization $C_{iK}^{KK} = (C_{iKN}^{K})^2/C_{iKN}^{NN}$ and are listed in Table III.
At low energies the Regge type of interactions is not realistic and rather \( V = \rho, \omega, \phi \) meson exchanges must be taken into account:

\[
A^{V-\text{exch.}}_{K^+K^0 \to K^+K^0} (\hat{t}_2) = g_{KKV} F_{KKV}(\hat{t}_2) \frac{(p^\mu_3 + p^\mu_4) P_{\mu\nu}(p^\nu_3 + p^\nu_4)}{\hat{t}_2 - m^2_v + i m_v \Gamma_V} g_{KKV} F_{KKV}(\hat{t}_2),
\]

\[
A^{V-\text{exch.}}_{K^-K^+ \to K^-K^+} (\hat{u}_2) = g_{KKV} F_{KKV}(\hat{u}_2) \frac{(p^\mu_3 + p^\mu_4) P_{\mu\nu}(p^\nu_3 + p^\nu_4)}{\hat{u}_2 - m^2_v + i m_v \Gamma_V} g_{KKV} F_{KKV}(\hat{u}_2),
\]

where \( P_{\mu\nu}(k) = -g_{\mu\nu} + k_\mu k_\nu/m^2_v \) and the \( KKV \) coupling constants \( g_{KKV} \) are given from SU(3) symmetry relations 2.28 \( g_{KK\omega} = \sqrt{2} g_{KK\phi} = 2 g_{KK\rho} = g_{\rho\pi\pi} = 6.04 \) [28], where the value of \( g_{\rho\pi\pi} \) is determined by the decay width of the \( \rho \) meson.

![Diagram](image)

**FIG. 4**: The central diffractive mechanism of exclusive production of \( K^+K^- \) pairs via the \( K^*(892) \) meson exchanges.

Again the \( \pi\pi \to KK \) subprocess amplitude is written in the high-energy approximation as

\[
\frac{F^2_\pi(\hat{t})}{\hat{t} - m^2_\pi} \to \frac{i}{16\pi^2 s} \int d^2 \hat{\kappa} \frac{F^2_\pi(\hat{t}_1)}{\hat{t}_1 - m^2_\pi} M^{K^* - \text{exch.}}_{\pi\pi \to K^+K^-} (\hat{t}_2),
\]

\[
\frac{F^2_\pi(\hat{u})}{\hat{u} - m^2_\pi} \to \frac{i}{16\pi^2 s} \int d^2 \hat{\kappa} \frac{F^2_\pi(\hat{u}_1)}{\hat{u}_1 - m^2_\pi} M^{K^* - \text{exch.}}_{\pi\pi \to K^-K^+} (\hat{u}_2),
\]

with

\[
M^{K^* - \text{exch.}}_{\pi\pi \to K^+K^-} (\hat{t}_2) = g_{\pi KK^*} F_{\pi KK^*}(\hat{t}_2) \frac{(p^\mu_3 + p^\mu_4) P_{\mu\nu}(p^\nu_3 + p^\nu_4)}{\hat{t}_2 - m^2_{K^*} + i m_{K^*} \Gamma_{K^*}} g_{\pi KK^*} F_{\pi KK^*}(\hat{t}_2),
\]

\[
M^{K^* - \text{exch.}}_{\pi\pi \to K^-K^+} (\hat{u}_2) = g_{\pi KK^*} F_{\pi KK^*}(\hat{u}_2) \frac{(p^\mu_3 + p^\mu_4) P_{\mu\nu}(p^\nu_3 + p^\nu_4)}{\hat{u}_2 - m^2_{K^*} + i m_{K^*} \Gamma_{K^*}} g_{\pi KK^*} F_{\pi KK^*}(\hat{u}_2),
\]

where now \( P_{\mu\nu}(k) = -g_{\mu\nu} + k_\mu k_\nu/m^2_{K^*} \) and we take \( g_{\pi KK^*} = -\frac{1}{2} g_{\rho\pi\pi} \) [28].

The quantities \( F(k^2) \) in Eqs (2.13, 2.15) describe couplings of extended \( \omega \) and \( K^* \) mesons, respectively, and are parameterized in the exponential form:

\[
F(k^2) = \exp \left( \frac{B_V}{4} (k^2 - m^2_\nu) \right).
\]

Consistent with the definition of the coupling constant the form factors are normalized to unity when \( \omega \) or \( K^* \) meson is on-mass-shell. We take \( B_V = 4 \text{ GeV}^{-2} \).
The amplitudes given by formula (2.15) are corrected by the factors \( \left( \frac{s}{s_0} \right)^{\alpha_{K^*}(k^2)-1} \) to reproduce the high-energy Regge dependence. We take \( K^* \) meson trajectory as \( \alpha_{K^*}(k^2) = 0.25 + \alpha'_{K^*} k^2 \), with \( \alpha'_{K^*} = 0.83 \text{ GeV}^{-2} \) [25].

The cross section is obtained by integration over the four-body phase space, which is reduced to 8-dimensions and performed numerically

\[
\sigma = \int \frac{1}{2s} |\mathcal{M}|^2 (2\pi)^4 \delta^4(p_a + p_b - p_1 - p_2 - p_3 - p_4) \frac{d^3p_1}{(2\pi)^3 2E_1} \frac{d^3p_2}{(2\pi)^3 2E_2} \frac{d^3p_3}{(2\pi)^3 2E_3} \frac{d^3p_4}{(2\pi)^3 2E_4}.
\]

The details how to conveniently reduce the number of kinematical integration variables are given e.g. in [6].

III. OTHER DIFFRACTIVE PROCESSES

Up to now we have discussed only central diffractive contribution to the \( pp \rightarrow ppK^+K^- \) reaction. In general, there are also contributions with other diffractive processes shown in Fig.5, not evaluated so far in the literature. It is straightforward to evaluate the new diffractive contributions of diagrams a) - e) and the Born amplitudes are given below:

\[
\mathcal{M}^{(a)}_{\lambda_a \lambda_b \rightarrow \lambda_1 \lambda_2} = \bar{u}(p_1, \lambda_1) i \gamma_5 S_A(p^2_{1f}) i \gamma_5 S_A(p^2_{1fp}) u(p_a, \lambda_a) g_{\Lambda KN}^2 F^2_{p}(p^2_{1f}) F^2_{A}(p_{1fl})
\]

\[
\times i s C_{\Lambda N}^{\Lambda N} \left( \frac{s}{s_0} \right)^{\alpha_{P}(t_2)-1} \exp \left( \frac{B_{\Lambda N}^{NN}t_2}{2} \right) \delta_{\lambda_2 \lambda_b}, \tag{3.1}
\]

\[

\]

(3.3)

(3.4)

(3.5)

where \( s_0 = 1 \text{ GeV}^2 \) and \( s_{th}^K = (m_N + m_K)^2 \). In the above equations \( u(p_i, \lambda_i) = u^\dagger(p_f, \lambda_f) \gamma^0 \) are the Dirac spinors (normalized as \( \bar{u}(p) u(p) = 2m_N \)) of the initial and outgoing protons with the four-momenta \( p \) and the helicities \( \lambda \). Here \( s_{ij} = (p_i + p_j)^2 \), \( s_{ijk} = (p_i + p_j + p_k)^2 \) are squared invariant masses of the (\( i, j \)) and (\( i, j, k \)) systems. The four-momenta squared of the virtual particles are: \( p_{1i2i2i}^2 = (p_{a,b} - p_3)^2 \), \( p_{1f2f2f}^2 = (p_{1,2} + p_4)^2 \), \( p_{1i2i2i}^2 = (p_{1i2i} - p_{1,2})^2 \), \( p_{1fk2fk}^2 = (p_{a,b} - p_{1i2i})^2 \), \( p_{1ip2ip}^2 = (p_{1i2i} - p_4)^2 \), \( p_{1fp2fp}^2 = (p_{1f2f} + p_3)^2 \). While the four-momenta squared of transferred kaons and protons are less than \( m_\Lambda^2 \), the propagators for the intermediate particles are respectively

\[
S_K(k^2) = \frac{i}{k^2 - m_K^2},
\]

\[
S_p(k^2) = \frac{i(k_\mu \gamma^\mu + m_N)}{k^2 - m_N^2},
\]

\[
S_\Lambda(k^2) = \frac{i(k_\mu \gamma^\mu + m_\Lambda)}{k^2 - m_\Lambda^2}.
\]

(3.6)

The form factors, \( F_i(k^2) \), correct for the off-shellness of the virtual particles and are parameterised as

\[
F_i(k^2) = \exp \left( \frac{-|k^2 - m_i^2|}{\Lambda_{off}^2} \right),
\]

(3.7)

where the parameter \( \Lambda_{off} = 1 \text{ GeV} \) is taken in practical calculations. In our calculation the \( \Lambda KN \) coupling constant is taken as \( g_{\Lambda KN}^2 = 14 \text{ GeV}^2 \).

The Regge parameters in diagram (b) in Fig. 5 (see Eq. (3.3)) are not known precisely and are assumed to be \( C_{F}^{\Lambda N} \approx C_{F}^{NN} \) (see Table 1) and \( B_{F}^{\Lambda N} \approx B_{F}^{NN} = 9 \text{ GeV}^2 \). To reproduce the high-energy Regge dependence the amplitudes given in Eqs (3.3 - 3.5) are corrected,
e.g. the amplitude of (3.4) is multiplied by a factor $\left( s_{134}/s_{th}^{KK}\right) s_{K}(p_{1k}^{2})^{-1}$. The parameters of the Regge trajectories used in the calculation are given as $\alpha_{K}(k^{2}) = 0.7(k^{2} - m_{K}^{2})$, $\alpha_{p}(k^{2}) = -0.3 + 0.9k^{2}$, $\alpha_{\Lambda}(k^{2}) = -0.6 + 0.9k^{2}$ for the kaon, proton and $\Lambda$ exchanges, respectively.

Finally we consider the $\pi\pi \rightarrow KK$ rescattering mechanism shown in Fig. 6 which is particularly important rather at lower energies, e.g. for experiment PANDA to be built at GSI Darmstadt. We write the Born amplitude according to Feynman rules as

$$M_{\pi\pi \rightarrow KK}^{\pi\pi-KK}(\hat{t}, \hat{u}) = \bar{u}(p_1, \lambda_1)i\gamma_{5}u(p_a, \lambda_a)S_{\pi}(t_1)g_{\pi NN}F_{\pi NN}(t_1)F_{\pi K^*K}(t_1)$$

$$\left( M_{\pi\pi \rightarrow K^+K^-}^{K^*-exch.}(\hat{t}) + M_{\pi\pi \rightarrow K^-K^*}^{K^*-exch.}(\hat{u}) \right)$$

$$\bar{u}(p_2, \lambda_2)i\gamma_{5}u(p_b, \lambda_b)S_{\pi}(t_2)g_{\pi NN}F_{\pi NN}(t_2)F_{\pi K^*K}(t_2), \quad (3.8)$$

where $g_{\pi NN}^{2}/4\pi = 13.5$ value is taken and the $M_{\pi\pi \rightarrow KK}^{K^*-exch.}$ amplitudes are given by Eq. (2.15).

IV. RESULTS

Now we wish to show results and predictions for existing and future experiments. We start with DPE mechanism which dominates at midrapidities. In Fig. 7 we show the two-kaon invariant mass distribution at the center-of-mass energy of the CERN ISR $\sqrt{s} = 62$ GeV [12]. In this calculation the experimental cuts on the rapidity of both kaons and on longitudinal momentum fractions (Feynman-$x$, $x_F = 2p_{\perp}/\sqrt{s}$) of both outgoing protons are included. The experimental data show some small peaks above our flat model continuum. They correspond to the $K^+K^-$ resonances (e.g. $f_2(1270)$, $f'_2(1525)$) which are not included explicitly in our calculation. In the present analysis we are interested mostly what happens above the region $M_{KK} > 2 - 3$ GeV (see right panel). The results depend on the value of the nonperturbative, a priori unknown parameter of the form factor responsible for off-shell effects (see Eq. (2.8)). Our model with $\Lambda_{off}^2 = 2 GeV^2$ cut-off parameter fitted to the data provides an educated extrapolation to the unmeasured region. We compare results without (dotted lines) and with absorption corrections including the $KK$-rescattering effect (solid line). At the $\chi_{c0}$ mass the $KK$-rescattering leads to an enhancement of the cross section compared to the calculation without $KK$-rescattering. Below we shall use also this background predictions when analyzing the signal ($\chi_{c0}$) to background ratio.

In Fig. 8 we show differential distributions for the $pp \rightarrow ppK^+K^-$ reaction at $\sqrt{s} = 7$ TeV without (dotted line) and with (solid line) the absorptive corrections. In most distributions
FIG. 7: Differential cross section $d\sigma/dM_{KK}$ for the $pp \rightarrow ppK^+K^-$ reaction at $\sqrt{s} = 62$ GeV with experimental cuts relevant for the CERN ISR experimental data from Ref. [12]. Right panel shows the same in logarithmic scale. Results without (dotted line) and with (solid line) absorption effects are shown. Here $\Lambda_{off}^2 = 2\text{ GeV}^2$ and $\Lambda_{int} = 2\text{ GeV}$.

the shape is almost unchanged. The only exception is the distribution in proton transverse momentum where we predict a damping of the cross section at small proton $p_t$ and an enhancement of the cross section at large proton $p_t$.

In Fig. 8 we show differential distributions in kaon rapidity $y_K = y_3 = y_4$ for the $pp \rightarrow ppK^+K^-$ reaction at $\sqrt{s} = 0.5, 1.96, 7\text{ TeV}$ without (upper lines) and with (bottom lines) absorption effects. The integrated cross section slowly rises with incident energy. The reader is asked to notice that the energy dependence of the cross section at $y_K \approx 0$ is reversed by the absorption effects which are stronger at higher energies. In our calculation we include both Pomeron and Reggeon exchanges. The camel-like shape of the distributions is due to the interference of the components in the amplitude. In Fig. 9 we show the distribution in $y_K = y_3 = y_4$ for all ingredients included (thick solid line) and when only Pomeron exchanges are included (solid line), separately for Pomeron-Reggeon (Reggeon-Pomeron) exchanges which peaks at backward (forward) kaon rapidities and in the case when only Reggeon exchanges are included (dashed line).

In Fig. 11 we show distributions in the two-dimensional ($y_3, y_4$) space at $\sqrt{s} = 0.5, 1.96, 7\text{ TeV}$ for the central diffractive contribution. The cross section grows with $\sqrt{s}$. At high energies the kaons are emitted preferentially in the same hemispheres, i.e. $y_3, y_4 > 0$ or $y_3, y_4 < 0$. In this calculation the cut-off parameter $\Lambda_{off}^2 = 2\text{ GeV}^2$.

In Fig. 12 we show distributions in the $(p_{t,K}, M_{KK})$ space at $\sqrt{s} = 0.5, 7\text{ TeV}$ for the central diffractive contribution. As expected we observe strong correlation between the two variables.

Now we wish to compare differential distributions of kaon from the $\chi_{c0}$ decay with those for the continuum kaons. The amplitude for exclusive central diffractive $\chi_{c0}$ meson production was calculated within the $k_t$-factorization approach including virtualities of active gluons [13] and the corresponding cross section is calculated with the help of unintegrated gluon distribution functions (UGDFs) known from the literature. We apply the following
FIG. 8: Differential cross sections for the $pp \to pp K^+ K^-$ reaction at $\sqrt{s} = 7$ TeV without (dotted line) and with (solid line) the absorption effects. These calculations were done with the cut-off parameter $\Lambda_{off}^2 = 2$ GeV$^2$ and $\Lambda_{int} = 2$ GeV.

simple procedure. First we calculate the two-dimensional distribution $d\sigma(y, p_t)/dy dp_t$, where $y$ is rapidity and $p_t$ is the transverse momentum of $\chi_{c0}$. The decay of $\chi_{c0} \to K^+ K^-$ is included then in a simple Monte Carlo program assuming isotropic decay of the scalar $\chi_{c0}$ meson in its rest frame. The kinematical variables of kaons are transformed to the overall center-of-mass frame where extra cuts are imposed. Including the simple cuts allows us to construct several differential distributions in different kinematical variables.

In Fig. 13 we show two-kaon invariant mass distribution for the central diffractive $KK$ continuum and the contribution from the decay of the $\chi_{c0}$ meson (see the peak at $M_{KK} \simeq 3.4$ GeV) and the contribution from the decay of the $\phi$ meson. The cross section for exclusive production of the $\phi$ meson has been calculated within a pQCD $k_t$-factorization approach in Ref. [30]. In these figures the resonant $R = \phi, \chi_{c0}$ distributions was parameterized in the
FIG. 9: Differential cross section $d\sigma/dy_K$ for the $pp \rightarrow ppK^+K^-$ reaction at $\sqrt{s} = 0.5, 1.96, 7$ TeV with $\Lambda_{off}^2 = 2$ GeV$^2$. The results without (upper lines) and with (bottom lines) absorption effects due to $pp$-interaction and $KK$-rescattering are shown too.

FIG. 10: Differential cross section $d\sigma/dy_K$ for the $pp \rightarrow ppK^+K^-$ reaction at $\sqrt{s} = 7$ TeV with $\Lambda_{off}^2 = 2$ GeV$^2$. The different lines corresponds to the situation when all and only some components in the amplitude are included. The details are explained in the main text.

FIG. 11: Differential cross section in $(y_3, y_4)$ for the central diffractive contribution for three incident energies $\sqrt{s} = 0.5, 1.96, 7$ TeV. The absorption effects were included here.
Breit-Wigner form:

\[ \frac{d\sigma}{dM_{KK}} = B(R \rightarrow K^+K^-) \sigma_{pp \rightarrow ppR} \frac{1}{2M_{KK}} \frac{M_{KK} \Gamma_R}{\pi (M_{KK}^2 - m_R^2)^2 + M_{KK}^2 \Gamma_R^2}, \]

(4.1)

with parameters according to particle data book[20]. In the calculation of the \( \chi_{c0} \) distributions we use GRV94 NLO[31] and GJR08 NLO[32] collinear gluon distributions. The cross sections for the \( \phi \) and \( \chi_{c0} \) production and for the background include absorption effects. While the upper row shows the cross section integrated over the full phase space at different energies, the lower rows show results including the relevant kaon pseudorapidity restrictions \(-1 < \eta_{K^+}, \eta_{K^-} < 1 \) (RHIC and Tevatron) and \(-2.5 < \eta_{K^+}, \eta_{K^-} < 2.5 \) (LHC). Shown are only purely theoretical predictions. In reality the situation is, however, somewhat worse as both protons and, in particular, kaon pairs are measured with a certain precision which leads to an extra smearing in \( M_{KK} \). While the smearing is negligible for the background, it leads to a modification of the Breit-Wigner peak for the \( \chi_{c0} \) meson\(^1\). The results with more modern GJR UGDF are smaller by about a factor of 2-3 than those for somewhat older GRV UGDF.

In Fig. 14 we show distributions in kaon transverse momenta. The kaons from the \( \chi_{c0} \) decay are placed at slightly larger \( p_{t,K} \). This can be therefore used to get rid of the bulk of the continuum by imposing an extra cut on the kaon transverse momenta. It is not the case for the kaons from the \( \phi \) decay which are placed at lower \( p_{t,K} \).

In Table II we have collected numerical values of the integrated cross sections for exclusive production of \( K^+K^- \) at different energies. In Table III we have collected in addition numerical values of the integrated cross sections (see \( \sigma_{pp \rightarrow pp\chi_{c0}} \) in Eq. (4.1)) for exclusive \( \chi_{c0} \) production for some selected UGDFs at different energies.

In Fig. 15 we present rapidity distribution of \( K^+ \) (left panel) and rapidity distribution of \( K^- \) (right panel) including only diagrams shown in Fig. 5. The contribution for individual diagrams a) - e) are also shown. In the discussed here new mechanism not only protons but also kaons are produced dominantly in very forward or very background directions forming a large size gap in rapidity. Please note a very limited range of rapidities shown in the figure.

\(^1\) An additional experimental resolution not included here can be taken into account by an extra convolution of the Breit-Wigner shape with an additional Gaussian function.
FIG. 13: The $K^+K^-$ invariant mass distribution at $\sqrt{s} = 0.5, 1.96, 7$ TeV integrated over the full phase space (upper row) and with the detector limitations in kaon pseudorapidities (lower rows). The solid lines present the $KK$ continuum with the cut-off parameters $\Lambda^2_{off} = 2$ GeV$^2$. The $\chi_{c0}$ contribution is calculated with the GRV94 NLO (dotted lines) and GJR08 NLO (filled areas) collinear gluon distributions. The cross section for $\phi$ contribution at $\sqrt{s} = 7$ TeV is calculated as in [30]. The absorption effects were included in the calculations. Clear $\chi_{c0}$ signal with relatively small background can be observed.

The reggezation leads to an extra damping of the cross section. The cross section is much smaller than that for the DPE mechanism discussed above. It is particularly interesting that the distributions for $K^+$ and $K^-$ have slightly different shape.

Finally, the general situation at high energies is sketched in Fig.16. The discussed in this paper central diffractive (DD) contribution lays along the diagonal $y_3 = y_4$ and the classical DPE is placed in the center $y_3 \approx y_4$. While the contribution from diagrams in Fig.5 is predicted at $y_3, y_4 \sim y_{beam}$ or $y_3, y_4 \sim y_{target}$, the $\pi \pi \rightarrow KK$ contribution (see Fig.6) is
FIG. 14: Differential cross section \( d\sigma/dp_{t,K} \) at \( \sqrt{s} = 0.5, 1.96, 7 \) TeV with cuts on the kaon pseudorapidities. The diffractive background was calculated with the cut-off parameter \( \Lambda_{c-q}^2 = 2 \) GeV\(^2\). Results for the kaons from the decay of the \( \chi_{c0} \) meson including the \( K^+K^- \) branching ratio, for the GRV94 NLO (upper lines) and GJR08 NLO (bottom lines) UGDFs, are shown. In the right panel \( \phi \) meson contribution is shown in addition. The absorption effects were included here.

TABLE II: Integrated cross sections in \( \mu b \) (with absorption corrections) for exclusive \( K^+K^- \) production at different energies. In this calculations we have taken into account the relevant limitations in the kaon pseudorapidities \( |\eta_K| < 1 \) at RHIC and Tevatron, \( |\eta_K| < 2.5 \) at LHC.

| \( \sqrt{s} \) (TeV) | full phase space | with cuts on \( \eta_K \) |
|-----------------|------------------|------------------|
| 0.5             | 18.47            | 1.21             |
| 1.96            | 27.96            | 1.37             |
| 7               | 41.14            | 7.38             |

predicted at \( (y_3 \sim y_{beam} \quad \text{and} \quad y_4 \sim y_{target}) \) or \( (y_3 \sim y_{target} \quad \text{and} \quad y_4 \sim y_{beam}) \), i.e. well separated from the central diffractive contribution. The seperation in the \( (y_3, y_4) \) space can be used to seperate the two contributions experimentally.

V. CONCLUSIONS

In the present paper we have calculated several differential observables for the exclusive \( pp \rightarrow ppK^+K^- \) and \( p\bar{p} \rightarrow p\bar{p}K^+K^- \) reactions. The full amplitude of central diffractive process was calculated in a simple model with parameters adjusted to low energy data. The energy dependence of the amplitudes of the \( K\pi \) subsystems was parametrized in the Regge form which describes total and elastic cross section for the \( K\pi \) scattering. This parametrization includes both leading Pomeron trajectory as well as subleading Reggeon exchanges. We have predicted large cross sections for RHIC, Tevatron and LHC which allows to hope that presented by us distributions will be measured.

We have calculated also contributions of several diagrams where kaons are emitted from the proton lines. These mechanisms contribute at forward and backward regions and do not disturb the observation of the central DPE component.

At the Tevatron the measurement of exclusive production of \( \chi_c \) via decay in the \( J/\psi + \gamma \)
TABLE III: Integrated cross sections in nb (with absorption corrections) for exclusive $\chi_c^0$ production at different energies with the GRV94 NLO and GJR08 NLO collinear gluon distributions. In these calculations we have taken into account the relevant limitations in the kaon pseudorapidities $|\eta_K| < 1$ at RHIC and Tevatron, $|\eta_K| < 2.5$ at LHC and lower cut on both kaon transverse momenta $|p_{t,K}| > 1.5$ GeV.

| $\sqrt{s}$ (TeV) | full phase space | with cuts on $\eta_K$ | with cuts on $\eta_K$ and $p_{t,K}$ |

FIG. 15: Differential cross sections $d\sigma/dy_{K^+}$ (left panel) and $d\sigma/dy_{K^-}$ (right panel) for the $pp \rightarrow pp K^+ K^-$ reaction at $\sqrt{s} = 7$ TeV. The solid line represents the coherent sum of all amplitudes. The dotted, dashed, dash-dotted, long-dashed, long-dash-dotted lines correspond to contributions from a) - e) diagrams in Fig.5. The upper (blue online) lines correspond to contributions without reggeization of $\Lambda$ propagator in diagrams b), c), e).

channel cannot provide production cross sections for different species of $\chi_c$. In this decay channel the contributions of $\chi_c$ mesons with different spins are similar and experimental resolution is not sufficient to distinguish them. At LHC situation should be better.

In the present paper we have analyzed a possibility to measure the exclusive production of $\chi_c^0$ meson in the proton-(anti)proton collisions at the LHC, Tevatron and RHIC via $\chi_c^0 \rightarrow K^+ K^-$ decay channel. We have performed detailed studies of several differential distributions and demonstrated how to impose extra cuts in order to improve the signal-to-background ratio. We have shown that relevant measurements at RHIC, Tevatron and LHC are possible. Since the cross section for exclusive $\chi_c^0$ production is much larger than for $\chi_c(1,2)$ and the branching fraction to the $KK$ channel for $\chi_c^0$ is larger than that for $\chi_c2$ ($\chi_c^1$ does not decay into two kaons) the two-kaon channel should provide an useful information
FIG. 16: A schematic localization of different mechanisms for the $pp \to ppK^+K^-$ reaction at high energies.

about the $\chi_{c0}$ exclusive production.
