The Wellposedness of FBSDEs (II)

Jianfeng Zhang†

Abstract. This paper is a continuation of [10], in which we established the well-posedness result and a comparison theorem for a class of one dimensional Forward-Backward SDEs. In this paper we extend the wellposedness result to high dimensional FBSDEs, and weaken the key condition in [10] significantly. Compared to the existing methods in the literature, our result has the following features: (i) arbitrary time duration; (ii) random coefficients; (iii) (possibly) degenerate forward diffusion; and (iv) no monotonicity condition.

Keywords: Forward-backward SDEs, wellposedness.

MSC 2000 Subject Classifications. Primary: 60H10

1 Introduction and Main Result

Assume $(\Omega, \mathcal{F}, P)$ is a complete probability space, $\mathcal{F}_0 \subset \mathcal{F}$, and $W$ is a $d$-dimensional standard Brownian motion independent of $\mathcal{F}_0$. Let $\mathbf{F} \triangleq \{\mathcal{F}_t\}_{0 \leq t \leq T}$ be the filtration generated by $W$ and $\mathcal{F}_0$, augmented by the null sets as usual. We study the following FBSDE:

\begin{align}
X_t &= X_0 + \int_0^t b(\omega, s, \Theta_s)ds + \int_0^t \sigma^\ast(\omega, s, X_s, Y_s)dW_s; \\
Y_t &= g(\omega, X_T) + \int_t^T f(\omega, s, \Theta_s)ds - \int_t^T Z_s dW_s.
\end{align}

*This is an old note written in 2005, but was never submitted for publication.

where $\Theta \triangleq (X, Y, Z)$ and $^*$ denotes the transpose. We assume that $X_0 \in \mathcal{F}_0$, $b, \sigma, f, g$ are progressively measurable, and for any $\theta \triangleq (x, y, z)$, $b, \sigma, f$ are $\mathcal{F}$-adapted and $g(\cdot, x) \in \mathcal{F}_T$. For simplicity we will always omit the variable $\omega$ in $b, \sigma, f, g$.

The wellposedness of FBSDEs has been studied by many authors (see, e.g. [1], [6], [5], [3], [4], [7], [8], and [9]). We refer the readers to [10] for a more detailed introduction on the subject. Motivated by studying numerical methods for (Markovian) FBSDEs (see [2]), in [10] we proved the following theorem.

**Theorem 1.1** Assume that all processes are one dimensional; that $b, \sigma, f, g$ are differentiable with respect to $x, y, z$ with uniformly bounded derivatives; and that

$$
\partial_y \sigma \partial_z b = 0; \quad \partial_y b + \partial_x \sigma \partial_z b + \partial_y \sigma \partial_z f = 0.
$$

Denote

$$
I_0^2 \triangleq E\left\{ |X_0|^2 + |g(0)|^2 + \int_0^T \left[ |b(t, 0, 0, 0)|^2 + |\sigma(t, 0, 0)|^2 + |f(t, 0, 0, 0)|^2 \right] dt \right\}. \quad (1.3)
$$

If $I_0^2 < \infty$, then FBSDE (1.1) has a unique solution $\Theta$ such that

$$
\|\Theta\|^2 \triangleq E\left\{ \sup_{0 \leq t \leq T} [|X_t|^2 + |Y_t|^2] + \int_0^T |Z_t|^2 dt \right\} \leq CI_0^2. \quad (1.4)
$$

After [10] has been accepted for publication, we find that Theorem 1.1 can be improved significantly. In the sequel we assume

$$
W \in \mathbb{R}^d, \quad X, b \in \mathbb{R}, \quad Y, f, g \in \mathbb{R}^n, \quad Z \in \mathbb{R}^{n \times d}, \quad \sigma \in \mathbb{R}^d. \quad (1.5)
$$

Here $W, Y, \text{et al}$ are considered as column vectors. Let $\partial$ denote partial derivatives with appropriate dimensions; and $| \cdot |$ denote the Euclidian norm. For example, $\partial_z b \in \mathbb{R}^{n \times d}, \partial_y \sigma \in \mathbb{R}^{d \times n}$ in an obvious way, and $|Y_t|^2 = Y_t^*Y_t, |Z_t|^2 = \text{tr} (Z_t^*Z_t)$. Our main result is the following theorem.

**Theorem 1.2** Assume that $b, \sigma, f, g$ are uniformly Lipschitz continuous in $x, y, z$; and that there exists a constant $c > 0$ such that

$$
\Lambda_t^4(y) \leq -c|\Lambda_t^3(y)|, \quad (1.6)
$$

where $\Lambda_t^3(y) \triangleq (X, Y, Z)$ and $^*$ denotes the transpose. We assume that $X_0 \in \mathcal{F}_0$, $b, \sigma, f, g$ are progressively measurable, and for any $\theta \triangleq (x, y, z)$, $b, \sigma, f$ are $\mathcal{F}$-adapted and $g(\cdot, x) \in \mathcal{F}_T$. For simplicity we will always omit the variable $\omega$ in $b, \sigma, f, g$.

The wellposedness of FBSDEs has been studied by many authors (see, e.g. [1], [6], [5], [3], [4], [7], [8], and [9]). We refer the readers to [10] for a more detailed introduction on the subject. Motivated by studying numerical methods for (Markovian) FBSDEs (see [2]), in [10] we proved the following theorem.

$$

Denote

$$
I_0^2 \triangleq E\left\{ |X_0|^2 + |g(0)|^2 + \int_0^T \left[ |b(t, 0, 0, 0)|^2 + |\sigma(t, 0, 0)|^2 + |f(t, 0, 0, 0)|^2 \right] dt \right\}. \quad (1.3)
$$

If $I_0^2 < \infty$, then FBSDE (1.1) has a unique solution $\Theta$ such that

$$
\|\Theta\|^2 \triangleq E\left\{ \sup_{0 \leq t \leq T} [|X_t|^2 + |Y_t|^2] + \int_0^T |Z_t|^2 dt \right\} \leq CI_0^2. \quad (1.4)
$$

After [10] has been accepted for publication, we find that Theorem 1.1 can be improved significantly. In the sequel we assume

$$
W \in \mathbb{R}^d, \quad X, b \in \mathbb{R}, \quad Y, f, g \in \mathbb{R}^n, \quad Z \in \mathbb{R}^{n \times d}, \quad \sigma \in \mathbb{R}^d. \quad (1.5)
$$

Here $W, Y, \text{et al}$ are considered as column vectors. Let $\partial$ denote partial derivatives with appropriate dimensions; and $| \cdot |$ denote the Euclidian norm. For example, $\partial_z b \in \mathbb{R}^{n \times d}, \partial_y \sigma \in \mathbb{R}^{d \times n}$ in an obvious way, and $|Y_t|^2 = Y_t^*Y_t, |Z_t|^2 = \text{tr} (Z_t^*Z_t)$. Our main result is the following theorem.

**Theorem 1.2** Assume that $b, \sigma, f, g$ are uniformly Lipschitz continuous in $x, y, z$; and that there exists a constant $c > 0$ such that

$$
\Lambda_t^4(y) \leq -c|\Lambda_t^3(y)|, \quad (1.6)
$$

where $\Theta \triangleq (X, Y, Z)$ and $^*$ denotes the transpose. We assume that $X_0 \in \mathcal{F}_0$, $b, \sigma, f, g$ are progressively measurable, and for any $\theta \triangleq (x, y, z)$, $b, \sigma, f$ are $\mathcal{F}$-adapted and $g(\cdot, x) \in \mathcal{F}_T$. For simplicity we will always omit the variable $\omega$ in $b, \sigma, f, g$. 
for any \( y \in \mathbb{R}^d \) such that \(|y| = 1\), where

\[
\Lambda^3_t(y) \triangleq \sum_{i=1}^{n} y_i \left[ \text{tr} \left( [\partial_z f^i][\partial_z b]^* \right) - y^* [\partial_z b][\partial_z f^i]^* y + y^* [\partial_y \sigma]^* [\partial_z f^i]^* y \right] \\
+ [\partial_z \sigma]^* [\partial_z b]^* y + [\partial_y b] y
\]

\[
\Lambda^4_t(y) \triangleq |\partial_z b|^2 - |[\partial_z b]^* y|^2 + 2y^* [\partial_z b][\partial_y \sigma] y.
\]

If \( I_0^2 < \infty \), then FBSDE (1.1) has a unique solution \( \Theta \) such that \( \|\Theta\|^2 \leq CI_0^2 \), where \( C \) depends on \( c \) and the Lipschitz constant of the coefficients.

We note that we only assume those partial derivatives involved in (1.7) exist. Moreover, when one part of a product vanishes, we do not need to assume the other part to be differentiable. For example, if \( \partial_z b = 0 \), then we do not need \( \partial_z \sigma \). In fact, we can even weaken (1.6) further by using approximating coefficients (see (2.13) at below).

Remark 1.3 Following are three sufficient conditions for (1.6):

\[
[\partial_z b][\partial_z b]^* - [\partial_y \sigma]^* [\partial_z b]^* - [\partial_z b][\partial_y \sigma] \geq |\partial_z b|^2 + c \text{Id}_n;
\]

(1.8)

\[
\partial_y b = 0, \quad \partial_z b = 0, \quad [\partial_y \sigma]^* [\partial_z f^i]^* = 0, i = 1, \ldots, n;
\]

(1.9)

\[
n = 1, \quad -[\partial_z b][\partial_y \sigma] \geq c|\partial_y b + [\partial_z f][\partial_y \sigma] + [\partial_z b][\partial_z \sigma]|;
\]

(1.10)

where \( \text{Id}_n \in \mathbb{R}^{n \times n} \) is the \( n \times n \) identity matrix.

Remark 1.4 (i) A necessary condition to ensure (1.8) is \( n \leq d \);

(ii) There are two typical cases for (1.9). One is that \( \partial_y \sigma = 0 \), then (1.1) becomes the standard decoupled FBSDE. The other one is that \( \partial_z f = 0 \), then (1.1) becomes

\[
\begin{aligned}
X_t &= X_0 + \int_0^t b(s, X_s) ds + \int_0^t \sigma^*(s, X_s, Y_s) dW_s; \\
Y_t &= g(X_T) + \int_t^T f(s, X_s, Y_s) ds - \int_t^T Z_s dW_s.
\end{aligned}
\]

(1.11)

We note that in this case it is allowed to have \( n > d \).

Theorem 1.2 improves Theorem 1.1 in three ways. First, there is more freedom on the dimensions; second, (1.10) is obviously much weaker than (1.2); and third, we allow the coefficients to be only Lipschitz continuous (instead of differentiable). We note that the third feature is not trivial because for coefficients satisfying (1.10) (or
(1.8)), their mollifiers may fail to satisfy so. We would also like to mention that, as in Theorem 1.1, our result has the following features: 1) $T$ can be arbitrarily large; 2) the coefficients are random; 3) $\sigma$ can be degenerate; 4) no monotonicity condition is required.

However, we should point out that our method does not work when $X$ is high dimensional, mainly due to the non-commuting property of matrices multiplication. We would leave this case for future research.

2 Small Time Duration

In this section we establish some important results for FBSDEs with small time duration $T$. First we recall a wellposedness result due to Antonelli [1].

**Lemma 2.1** Assume $b, \sigma, f$ have a uniform Lipschitz constant $K$, and $g$ has a uniform Lipschitz constant $K_0$. There exist constants $\delta_0$ and $C_0$, depending only on $K$ and $K_0$, such that for $T \leq \delta_0$, if $I_0^2 < \infty$, then (1.1) has a unique solution $\Theta$ and it holds that $\|\Theta\| \leq C_0 I_0$.

The following lemma, which estimates the $C_0$ at above in terms of $(K, K_0)$, is the key step for the proof of Theorem 1.2.

**Lemma 2.2** Consider the following linear FBSDE:

\[
\begin{align*}
X_t &= 1 + \int_0^t B_s ds + \int_0^t \Gamma_s^* dW_s; \\
Y_t &= GX_T + \int_T^T F_s ds - \int_T^T Z_s dW_s;
\end{align*}
\] (2.1)

where

\[
\begin{align*}
B_t &= \alpha^1_t X_t + \beta^1_t Y_t + \text{tr} (\gamma^1_t Z_t); \\
\Gamma_t &= \alpha^2_t X_t + \beta^2_t Y_t; \\
F_t &= \alpha^3_t X_t + \beta^3_t Y_t + [\text{tr} (\gamma^3_1 Z_t), \cdots, \text{tr} (\gamma^3_n Z_t)]^*; \\
\end{align*}
\]

and

\[
\alpha^1_t \in \mathbb{R}, \quad \beta^1_t, \alpha^3_t \in \mathbb{R}^n, \quad \alpha^2_t \in \mathbb{R}^d, \quad \beta^2_t, \gamma^1_t, \gamma^3_t \in \mathbb{R}^{d \times n}, \quad \beta^3_t \in \mathbb{R}^{n \times n}.
\]
Assume $|\alpha^i_t|, |\beta^i_t|, |\gamma^i_t| \leq K$, $|G| \leq K_0$; and

$$\Lambda^4_t(y) \leq -\frac{1}{K}|\Lambda^3_t(y)|,$$  \hspace{1cm} (2.2)

for any $y \in \mathbb{R}$ such that $|y| = 1$.

Let $\delta_0$ be as in Lemma 2.1. There exists a constant $C_k$, depending only on $K$ but independent of $K_0$, such that for any $T \leq \delta_0$, the solution to FBSDE (2.1) satisfies

$$|Y_0|^2 \leq |\bar{K}_0|^2 \triangleq [|K_0|^2 + 1]e^{C_k T} - 1. \hspace{1cm} (2.3)$$

In the sequel we use $C_K$ to denote a generic constant which depends only on $K$ and may vary from line to line. Recalling (1.7) one can easily check that, for linear FBSDE (2.1), we have

$$\Lambda^3_t(y) = \sum_{i=1}^n y_i \left[ \text{tr} (\gamma^{3,i}_t y^{3,i}_t) - y^*_i \gamma^{1*}_t \gamma^{3,i}_t + y^*_i \beta^{2*}_t \gamma^{3,i}_t \right] + \alpha^{2*}_t \gamma^1_t y + \beta^1_t y$$

$$\Lambda^4_t(y) = |\gamma^1_t|^2 - |\gamma^1_t y|^2 + 2y^* \beta^{2*}_t \gamma^1_t y. \hspace{1cm} (2.4)$$

We also note that $\text{tr} (AB) = \text{tr} (BA)$ for any matrices $A, B$ with appropriate dimensions.

Proof of Lemma 2.2. The proof is quite lengthy, we split it into two steps.

Step 1. We first assume $X_t \neq 0$ and formally derive some formulas. Note that

$$B_t \in \mathbb{R}; \quad \Gamma_t \in \mathbb{R}^d; \quad F_t \in \mathbb{R}^n.$$  

Apply Ito’s formula, we have

$$dX^{-2}_t = -2X^{-3}_t dX_t + 3X^{-4}_t \Gamma_t dt = -2X^{-3}_t \Gamma_t dW_t - \left[ 2X^{-3}_t B_t - 3X^{-4}_t \Gamma_t \Gamma_t \right] dt,$$

and

$$d|Y_t|^2 = d(Y^*_t Y_t) = 2Y^*_t dY_t + \text{tr} (Z_t Z^*_t) dt = 2Y^*_t Z_t dW_t - \left[ 2Y^*_t F_t - \text{tr} (Z_t Z^*_t) \right] dt.$$  

Denote

$$\tilde{Y}_t \triangleq Y_t X^{-1}_t; \quad \tilde{\Gamma}_t \triangleq \Gamma_t X^{-1}_t; \quad \tilde{Z}_t \triangleq Z_t X^{-1}_t - \tilde{Y}_t \tilde{\Gamma}^*_t; \quad d\tilde{W}_t \triangleq dW_t - [\tilde{\Gamma}_t + \gamma^1_t \tilde{Y}_t] dt. \hspace{1cm} (2.5)$$
Recalling that $|Z|^2 \triangleq \text{tr} (Z^2)$. Then

$$
d|\tilde{Y}_t|^2 = d(|Y_t|^2 |X_t|^2) = X_t^{-2} d|Y_t|^2 + |Y_t|^2 dX_t^{-2} + d < |Y|^2, X^{-2} >_t
= 2X_t^{-2}Y_t^* Z_t dW_t - X_t^{-2} |2Y_t^* F_t - |Z_t|^2| dt
- 2|Y_t|^2 X_t^{-3} \Gamma_t dW_t - |Y_t|^2 |2X_t^{-3} B_t - 3X_t^{-1}|\Gamma_t|^2| dt - 4X_t^{-3}Y_t^* Z_t \Gamma_t dt
= \left[ 2\tilde{Y}_t^* Z_t X_t^{-1} - 2|\tilde{Y}_t|^2 \tilde{\Gamma}_t \right] dW_t
- 2\tilde{Y}_t^* [\alpha_i^3 + \beta_i^2 \tilde{Y}_t] dt - 2\sum_{i=1}^n \tilde{Y}_t^i \text{tr} (\gamma_i^3 \tilde{Y}_t X_t^{-1}) dt + |Z_t X_t^{-1}|^2 dt
- 2|\tilde{Y}_t|^2 [\alpha_i^1 + \beta_i^1 \tilde{Y}_t + \text{tr} (\gamma_i^1 \tilde{Y}_t X_t^{-1})] dt + 3|\tilde{Y}_t|^2 |\tilde{\Gamma}_t|^2 dt - 4\tilde{Y}_t^* Z_t X_t^{-1} \tilde{\Gamma}_t dt
= 2\tilde{Y}_t^* \tilde{Z}_t d\tilde{W}_t + [\tilde{\Gamma}_t + \gamma_i^1 \tilde{Y}_t] dt + [\tilde{\Gamma}_t + \tilde{Y}_t \tilde{\Gamma}_t]^2 dt
- 2\tilde{Y}_t^* [\alpha_i^3 + \beta_i^2 \tilde{Y}_t] dt - 2\sum_{i=1}^n \tilde{Y}_t^i \text{tr} (\gamma_i^3 \tilde{Y}_t X_t^{-1}) dt - 4\tilde{Y}_t^* [\tilde{Z}_t + \tilde{Y}_t \tilde{\Gamma}_t] \tilde{\Gamma}_t dt
- 2\tilde{Y}_t^* [\alpha_i^3 + \beta_i^2 \tilde{Y}_t] dt - 2|\tilde{Y}_t|^2 [\alpha_i^1 + \beta_i^1 \tilde{Y}_t] dt + 3|\tilde{Y}_t|^2 |\tilde{\Gamma}_t|^2 dt
\geq 2\tilde{Y}_t^* \tilde{Z}_t d\tilde{W}_t - \left| \sum_{i=1}^n \tilde{Y}_t^i \gamma_i^3 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^2 \gamma_i^1 - \gamma_i^1 \tilde{Y}_t \tilde{Y}_t^* \right|^2 dt
- 2\tilde{Y}_t^* [\alpha_i^3 + \beta_i^2 \tilde{Y}_t] dt - 2\sum_{i=1}^n \tilde{Y}_t^i \text{tr} (\gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1) dt - 2|\tilde{Y}_t|^2 [\alpha_i^1 + \beta_i^1 \tilde{Y}_t] dt
= 2\tilde{Y}_t^* \tilde{Z}_t d\tilde{W}_t - \left| \sum_{i=1}^n \tilde{Y}_t^i \gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^4 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^2 \gamma_i^1 \tilde{\gamma}_i^1 \tilde{Y}_t \right|^2 dt
+ 2 \left| \sum_{i=1}^n \tilde{Y}_t^i \tilde{Y}_t^* \gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^4 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^2 \gamma_i^1 \tilde{\gamma}_i^1 \tilde{Y}_t \right|^2 dt
- 2\left[ [\alpha_i^2 + \beta_i^2 \tilde{Y}_t] \left( \sum_{i=1}^n \tilde{Y}_t^i \gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^4 \gamma_i^1 \tilde{\gamma}_i^1 \tilde{Y}_t + \tilde{Y}_t^* [\alpha_i^3 + \beta_i^3 \tilde{Y}_t] + |\tilde{Y}_t|^2 [\alpha_i^1 + \beta_i^1 \tilde{Y}_t] \right) dt
\geq 2\tilde{Y}_t^* \tilde{Z}_t d\tilde{W}_t - C_K [1 + |\tilde{Y}_t|^2] dt
- 2\left| \tilde{Y}_t^2 \sum_{i=1}^n \tilde{Y}_t^i \text{tr} (\gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1) - \sum_{i=1}^n \tilde{Y}_t^i \tilde{Y}_t^* \gamma_i^3 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^4 \alpha_i^2 \gamma_i^1 \tilde{Y}_t \right|^2 dt
+ \sum_{i=1}^n \tilde{Y}_t^i \tilde{Y}_t^* \beta_i^2 \gamma_i^3 \tilde{\gamma}_i^1 \tilde{Y}_t + |\tilde{Y}_t|^2 \beta_i^3 \tilde{Y}_t \right] dt
- \left[ |\tilde{Y}_t|^4 \gamma_i^1 \tilde{\gamma}_i^1 + |\tilde{Y}_t|^2 \gamma_i^1 \tilde{\gamma}_i^1 \tilde{Y}_t + 2|\tilde{Y}_t|^2 \tilde{Y}_t \beta_i^2 \gamma_i^1 \tilde{Y}_t \right] dt.
Denote $\bar{Y}_t \overset{\Delta}{=} \tilde{Y}_t|\tilde{Y}_t|^{-1}$ when $|\tilde{Y}_t| \neq 0$, and arbitrary unit vector otherwise. Then $|\tilde{Y}_t| = 1$ and

$$d|\tilde{Y}_t|^2 \geq 2\tilde{Y}_t^*\tilde{Z}_td\tilde{W}_t - CK[1 + |\tilde{Y}_t|^2]dt - \left[2|\tilde{Y}_t|^3\Lambda^3_t(\tilde{Y}_t) + |\tilde{Y}_t|^4\Lambda^4_t(\tilde{Y}_t)\right]dt. \quad (2.6)$$

**Step 2.** The arguments in this step are similar to those for Lemma 3.2 in [10], so we will only sketch the main idea.

Denote

$$\tau \overset{\Delta}{=} \inf\{t > 0 : X_t = 0\} \land T; \quad \tau_n \overset{\Delta}{=} \inf\{t > 0 : X_t = \frac{1}{n}\} \land T.$$ 

Then $\tau_n \uparrow \tau$ and $X_t > 0$ for $t \in [0, \tau)$. Recall (2.5) for $t \in [0, \tau)$. By Lemma 2.1 one can easily prove that $|Y_t| \leq C_0|X_t|$, and thus

$$|\tilde{Y}_t| \leq C_0, \quad \forall t \in [0, \tau). \quad (2.7)$$

By (2.2) we have

$$2|\tilde{Y}_t|^3\Lambda^3_t(\tilde{Y}_t) + |\tilde{Y}_t|^4\Lambda^4_t(\tilde{Y}_t) \leq -\frac{1}{K}|\Lambda^3_t(\tilde{Y}_t)||\tilde{Y}_t|^4 + 2|\tilde{Y}_t|^3|\Lambda^3_t(\tilde{Y}_t)| \leq K|\Lambda^3_t(\tilde{Y}_t)||\tilde{Y}_t|^2.$$ 

Note that $|\Lambda^3_t(\tilde{Y}_t)| \leq CK$. Thus

$$2|\tilde{Y}_t|^3\Lambda^3_t(\tilde{Y}_t) + |\tilde{Y}_t|^4\Lambda^4_t(\tilde{Y}_t) \leq CK|\tilde{Y}_t|^2. \quad (2.8)$$

Then by (2.6) one gets

$$d|\tilde{Y}_t|^2 \geq 2\tilde{Y}_t^*\tilde{Z}_td\tilde{W}_t - CK[1 + |\tilde{Y}_t|^2]dt; \quad (2.9)$$

In light of (2.5) we define

$$M_t = 1 + \int_0^t M_s[\tilde{\Gamma}_s + \gamma^1_s\tilde{Y}_s]^*1_{\{\tau > s\}}dW_s; \quad L_t = e^{CK^t},$$

for the $C_K$ in (2.9). By (2.7) $M$ is a martingale. Moreover,

$$d(L_tM_t|\tilde{Y}_t|^2) \geq (\cdots)dW_t - CKL_tM_tdt,$$

thanks to the obvious fact that $L_t > 0, M_t > 0$.

Now for each $n$, we have

$$|\tilde{Y}_0|^2 \leq L_{\tau_n}M_{\tau_n}|\tilde{Y}_{\tau_n}|^2 - \int_0^{\tau_n}(\cdots)dW_t + C_K\int_0^{\tau_n}L_tM_tdt.$$
Thus

\[ |\bar{Y}_0|^2 \leq E\left\{ \Gamma_{\tau_n} M_{\tau_n} |\bar{Y}_{\tau_n}|^2 + C_K \int_0^{\tau_n} L_t M_t dt \right\}. \tag{2.10} \]

On the other hand, if \( \tau = T \), \( |Y_{\tau}| = |Y_T| = |G X_T| = |G X_{\tau}| \leq K_0 |X_{\tau}| \). If \( \tau < T \), then \( X_{\tau} = 0 \), thus \( |Y_{\tau}| \leq C_0 |X_{\tau}| = 0 \). Therefore, in both cases it holds that \( |Y_{\tau}| \leq K_0 |X_{\tau}| \).

By the same arguments as in Lemma 3.2 of [10], one can prove that

\[ |\bar{Y}_{\tau_n}|^2 \leq |K_0|^2 + C_K E_{\tau_n}\{|\tau - \tau_n|^2\}, \]

which, combined with (2.10), implies that

\[
|\bar{Y}_0|^2 \leq E\left\{ \Gamma_{\tau_n} M_{\tau_n} [\|K_0\|^2 + C_K E_{\tau_n}\{|\tau - \tau_n|^2\}] + C_K \int_0^{\tau_n} L_t M_t dt \right\}
\]

Let \( n \to \infty \) and note that \( X_0 = 1 \), we prove (2.3).

\[ \Lambda^3_t(y) = -y, \quad \Lambda^4_t(y) = 0. \]

So (2.2) does not hold true. Note that \( \tilde{Y}_T = Y_TX_T^{-1} = 1 > 0 \). Actually one can prove in this example that \( \tilde{Y}_t > 0 \) for any \( t \), then

\[ 2|\tilde{Y}_t|^3 \Lambda^3_t(\tilde{Y}_t) + |\tilde{Y}_t|^4 \Lambda^4_t(\tilde{Y}_t) = -2\tilde{Y}_t^3 < 0, \]

which implies (2.8). So we still have \( |\bar{Y}_0| \leq K_0 \). Then by using the arguments in next section we can show that (2.11) is wellposed for arbitrary \( T \). In fact, (2.11) satisfies the monotonicity condition in [4], and thus its wellposedness is already known.
We would also like to mention that (2.8) is consistent with the four step scheme (see [5] and [3]) in the following sense. Assume an FBSDE in the four step scheme framework has two solutions \( \Theta^1, \Theta^2 \). Denote \( \check{Y}_t = [Y^1_t - Y^2_t][X^1_t - X^2_t]^{-1} \). Note that \( Y^i_t = u(t, X^i_t) \) and \( u \) is uniformly Lipschitz continuous in \( x \), where \( u \) is the solution to the corresponding PDE. Then \( \check{Y}_t \) is uniformly bounded and thus (2.8) holds true.

The following result connects FBSDEs (1.1) and (2.1).

**Corollary 2.3** Assume that all the conditions in Lemma 2.1 as well as (1.6) hold true with \( c = \frac{1}{K} \). Let \( T \leq \delta_0 \) as in Lemma 2.1, and \( \Theta^i, i = 0, 1, \) be the solution to FBSDEs:

\[
\begin{align*}
X^i_t &= x_i + \int_0^t b(s, \Theta^i_s)ds + \int_0^t \sigma^*(s, X^i_s, Y^i_s)dW_s; \\
Y^i_t &= g(X^i_T) + \int_t^T f(s, \Theta^i_s)ds - \int_t^T Z^i_s dW_s.
\end{align*}
\]

Then \(|Y^1_0 - Y^0_0| \leq \bar{K}_0|x_1 - x_0|\), where \( \bar{K}_0 \) is defined in (2.3).

**Proof.** We first assume that all the coefficients are differentiable. For \( 0 \leq \lambda \leq 1 \), let \( \Theta^\lambda \triangleq (X^\lambda, Y^\lambda, Z^\lambda) \) and \( \nabla \Theta^\lambda \triangleq (\nabla X^\lambda, \nabla Y^\lambda, \nabla Z^\lambda) \) be the solutions to FBSDEs:

\[
\begin{align*}
X^\lambda_t &= x_0 + \lambda(x_1 - x_0) + \int_0^t b(s, \Theta^\lambda_s)ds + \int_0^t \sigma^*(s, X^\lambda_s, Y^\lambda_s)dW_s; \\
Y^\lambda_t &= g(X^\lambda_T) + \int_t^T f(s, \Theta^\lambda_s)ds - \int_t^T Z^\lambda_s dW_s.
\end{align*}
\]

and

\[
\begin{align*}
\nabla X^\lambda_t &= 1 + \int_0^t \left[ \partial_x b(s, \Theta^\lambda_s)\nabla X^\lambda_s + \partial_y b(s, \Theta^\lambda_s)\nabla Y^\lambda_s + \text{tr} (\partial_z b^*(s, \Theta^\lambda_s)\nabla Z^\lambda_s) \right]ds \\
&\quad + \int_0^t \left[ \partial_x \sigma(s, \Theta^\lambda_s)\nabla X^\lambda_s + \partial_y \sigma(s, \Theta^\lambda_s)\nabla Y^\lambda_s \right]dW_s; \\
\nabla Y^\lambda_t &= \partial_x g(X^\lambda_T)\nabla X^\lambda_T - \int_t^T \nabla Z^\lambda_s dW_s \\
&\quad + \int_t^T \left[ \partial_x f(s, \Theta^\lambda_s)\nabla X^\lambda_s + \partial_y f(s, \Theta^\lambda_s)\nabla Y^\lambda_s + \sum_{j=1}^n \text{tr} (\partial_z f^{j*}(s, \Theta^\lambda_s)\nabla Z^\lambda_{s}) \right]ds;
\end{align*}
\]

respectively. One can easily prove that

\[
\Theta^1_t - \Theta^0_t = \int_0^1 \frac{d}{d\lambda} \Theta^\lambda_t d\lambda = [x_1 - x_0] \int_0^1 \nabla \Theta^\lambda_t d\lambda.
\]

In particular,

\[
Y^1_0 - Y^0_0 = [x_1 - x_0] \int_0^1 \nabla Y^\lambda_0 d\lambda.
\]
Note that (1.6) implies (2.2) for FBSDE (2.12). Then by Lemma 2.2 we have $|\nabla Y_0^\lambda| \leq \bar{K}_0$, and thus
$$|Y_0^1 - Y_0^0| \leq |x_1 - x_0| \int_0^1 |\nabla Y_0^\lambda| d\lambda \leq \bar{K}_0 |x_1 - x_0|.$$  

In general case, for any $\epsilon > 0$, we may find mollifiers $(b^\epsilon, \sigma^\epsilon, f^\epsilon, g^\epsilon)$ such that
\begin{equation}
\Lambda_4^{\lambda, \epsilon}(y) \leq -\frac{1}{K}|\Lambda_3^{\lambda, \epsilon}(y)| + \epsilon, \tag{2.13}
\end{equation}

where $\Lambda_3^{\lambda, \epsilon}$ and $\Lambda_4^{\lambda, \epsilon}$ are defined in an obvious way, so are other terms such as $\Theta^{\lambda, \epsilon}$. Denote $\bar{Y}_t^{\lambda, \epsilon} \triangleq \nabla Y_t^{\lambda, \epsilon}[\nabla X_t^{\lambda, \epsilon}]^{-1}$. By Lemma 2.1 we have $|\bar{Y}_t^{\lambda, \epsilon}| \leq C_0$ where $C_0$ may depend on $K_0$ though. Then we have
\begin{align*}
2|\bar{Y}_t^{\lambda, \epsilon}|^3 \Lambda_3^{\lambda, \epsilon}(\bar{Y}_t^{\lambda, \epsilon}) + |\bar{Y}_t^{\lambda, \epsilon}|^4 \Lambda_4^{\lambda, \epsilon}(\bar{Y}_t^{\lambda, \epsilon}) \\
\leq 2|\bar{Y}_t^{\lambda, \epsilon}|^3 \Lambda_3^{\lambda, \epsilon}(\bar{Y}_t^{\lambda, \epsilon}) + |\bar{Y}_t^{\lambda, \epsilon}|^4 \left(-\frac{1}{K}|\Lambda_3^{\lambda, \epsilon}(y)| + \epsilon\right) \\
\leq C_K |\bar{Y}_t^{\lambda, \epsilon}|^2 + \epsilon |\bar{Y}_t^{\lambda, \epsilon}|^4 \leq [C_K + \epsilon C_0^2] |\bar{Y}_t^{\lambda, \epsilon}|^2. \tag{2.14}
\end{align*}

Now for $\epsilon \leq C_0^{-2}$, we know (2.8) holds true for $\bar{Y}_t^{\lambda, \epsilon}$, and thus $|Y_0^{1, \epsilon} - Y_0^{0, \epsilon}| \leq \bar{K}_0 |x_1 - x_0|$. Let $\epsilon \to 0$, the lemma follows from the stability result for FBSDEs over small time duration (see [1]).

\section{3 Proof of Theorem 1.2}

We now prove Theorem 1.2 for arbitrarily large $T$. The arguments are exactly the same as in [10]. So again we will only sketch the main idea. In the sequel we use $L_{\phi}$ to denote the smallest Lipschitz constant of a function $\phi$.

\textbf{Proof.} Let $K$ and $K_0$ be as in Lemma 2.1. By otherwise choosing larger $K$, without loss of generality we assume that $c = \frac{1}{K}$ in (1.6). Define $\bar{K}_0$ as in (2.3) (for the arbitrarily large $T$!). Let $\delta_0$ be a constant as in Lemma 2.1, but corresponding to $(K, \bar{K}_0)$ instead of $(K, K_0)$. Assume $(m-1)\delta_0 < T \leq m\delta_0$ for some integer $m$. Denote $T_i \triangleq \frac{T}{m}, i = 0, \ldots, m$. Define a mapping $g_m : \Omega \times \mathbb{R} \to \mathbb{R}$ by $g_m(\omega, x) \triangleq g(\omega, x)$. Now for $t \in [T_{m-1}, T_m]$, consider the following FBSDE:
\begin{align*}
X_t^m &= x + \int_{T_{m-1}}^t b(s, \Theta_s^m) ds + \int_{T_{m-1}}^t \sigma^*(s, X_s^m, Y_s^m) dW_s; \\
Y_t^m &= g_m(X_{T_m}^n) + \int_t^{T_m} f(s, \Theta_s^m) ds - \int_t^{T_m} Z_s^m dW_s.
\end{align*}
Note that $L_{g_m} \leq K_0 \leq \bar{K}_0$, by Lemma 2.1 the above FBSDE has a unique solution for any $x$. Define $g_{m-1}(x) \triangleq Y_{T_{m-1}}^m$. Then for fixed $x$, $g_{m-1}(x) \in \mathcal{F}_{T_{m-1}}$. Moreover, by Corollary 2.3 we have

$$|L_{g_{m-1}}|^2 \leq |K_1|^2 \triangleq ||K_0|^2 + 1|e^{C_k(T_m-T_{m-1})} - 1 \leq |\bar{K}_0|^2.$$

Next we consider the following FBSDE over $[T_{m-2}, T_{m-1}]$:

\[
\begin{cases}
X_{t}^{m-1} = x + \int_{T_{m-2}}^{t} b(s, \Theta_s^{m-1})ds + \int_{T_{m-1}}^{t} \sigma^*(s, X_s^{m-1}, Y_s^{m-1})dW_s, \\
Y_{t}^{m-1} = g_{m-1}(X_{T_{m-1}}^{m-1}) + \int_{t}^{T_{m-1}} f(s, \Theta_s^{m-1})ds - \int_{t}^{T_{m-1}} Z_{s}^{m-1}dW_s.
\end{cases}
\]

Similarly we may define $g_{2}(x)$ such that

$$|L_{g_{2}}|^2 \leq |K_2|^2 \triangleq ||K_1|^2 + 1|e^{C_k(T_{m-1}-T_{m-2})} - 1 = ||K_0|^2 + 1|e^{C_k(T_m-T_{m-2})} - 1 \leq \bar{K}_0.$$

Repeat the arguments for $i = m, \cdots, 1$, we may define $g_i$ such that

$$|L_{g_i}|^2 \leq |K_{m-i}|^2 \triangleq ||K_0|^2 + 1|e^{C_k(T_{m-T_i})} - 1 \leq \bar{K}_0.$$

Now for any $X_0 \in L^2(\mathcal{F}_0)$, we may construct the solution to FBSDE (1.1) piece by piece over subintervals $[T_{i-1}, T_i]$ with terminal condition $g_i$, $i = 1, \cdots, n$. Since on each subinterval the solution is unique, we obtain the uniqueness of the solution to FBSDE (1.1). Finally, the estimate $||\Theta|| \leq CI_0$ can also be obtained by piece by piece estimates, as done in [10].

Finally we state the stability result whose proof is exactly the same as in [10] and thus is omitted.

**Theorem 3.1** Assume $(b^i, \sigma^i, f^i, g^i, X^i_0), i = 0, 1$, satisfy all the conditions in Theorem 1.2. Let $\Theta^i$ be the corresponding solutions, $\Delta \Theta \triangleq \Theta^1 - \Theta^0$, $\Delta g \triangleq g_1 - g_0$, and define other terms similarly. Then

$$||\Delta \Theta||^2 \leq CE\{||\Delta X_0||^2 + |\Delta g(X^1_0)|^2 + \int_0^T [||\Delta b||^2 + |\Delta \sigma|^2 + |\Delta f|^2](t, \Theta^1_t)dt\}.$$

**Corollary 3.2** Assume $(b^n, \sigma^n, f^n, g^n, X^n_0), n = 0, 1, \cdots$ satisfy all the conditions in Theorem 1.2 uniformly; $X^n_0 \to X^0_0$ in $L^2$; for $\varphi = b, \sigma, f, g$ and for any $(t, \theta)$, $\varphi^n(t, \theta) \to \varphi^0(t, \theta)$ as $n \to \infty$; and

$$E\{||X^n_0 - X_0||^2 + |g^n - g^0|^2(0) + \int_0^T [||b^n - b^0||^2 + |\sigma^n - \sigma^0|^2 + |f^n - f^0|^2](t, 0, 0, 0)dt\} \to 0.$$

Let $\Theta^n$ denote the corresponding solutions. Then $||\Theta^n - \Theta^0|| \to 0$.
