Abstract

We study the flavor changing $t \rightarrow c H^0$ decay in the framework of the general two Higgs doublet model, so called model III. Here, we take the Yukawa couplings complex and switch on the CP violating effects. We predict the branching ratio six orders larger compared to the one calculated in the SM, namely $BR \sim 10^{-7}$, and observe a measurable CP asymmetry, at the order of $\sim 10^{-2}$.

1 Introduction

The top quark reaches great interest since it breaks the $SU(2) \times U(1)$ symmetry maximally and it has rich decay products due to its large mass. The rare decays of the top quark have been studied in the literature, in the framework of the standard model (SM) and beyond [1]-[10]; the one-loop flavor changing transitions $t \to cg(\gamma, Z)$ in [5, 8] and $t \to cH^0$ in [3, 8, 9, 10].

In the SM, these decays are suppressed as a result of Glashow-Iliopoulos-Miaiani (GIM) mechanism [11]. The branching ratios (BR) of the decays $t \to cg(\gamma, Z)$ have been predicted in the SM as $4 \times 10^{-11} (5 \times 10^{-13}, 1.3 \times 10^{-13})$ in [8]. $t \to cH^0$, which can give strong clues about the nature of electroweak symmetry breaking, has been calculated at the order of the magnitude of $10^{-14} - 10^{-13}$ in the SM, in [3]. These are small rates for the measurement, even at the highest luminosity accelerators and therefore, there is a need to analyse these rare decays in a new physics beyond the SM.

In the present work, we study the flavor changing $t \to cH^0$ decay in the framework of the general two Higgs doublet model (model III), where $H^0$ is the SM Higgs boson. Here, we take the Yukawa couplings complex and switch on the CP violating effects. Since the BR is at the order of $\sim 10^{-13}$ in the SM, we neglect this contribution and calculate the new physics effects in the model III. In the calculations, we take into account the interactions due to the internal mediating charged Higgs boson $H^\pm$ and neglect the ones including internal neutral Higgs bosons, $h^0$ and $A^0$ (see Discussion part). The numerical results show that the $BR$ of this process can reach to the values of order $10^{-6}$, playing with the free parameters of the model III, respecting the existing experimental restrictions. This prediction is almost seven orders larger compared to the one in the SM and it is a measurable quantity in the accelerators.

Furthermore, we predict the possible CP asymmetry $A_{CP}$ at the order of $10^{-2}$ for the intermediate values of the CP parameter, due to the complex Yukawa coupling $\xi_D^{N,bb}$ (see section 2 for its definition). This is purely a new physics effect and the measurement of $A_{CP}$ for the process under consideration may open a new window to go beyond the SM and test the new physics.

The paper is organized as follows: In Section 2, we present the $BR$ and $A_{CP}$ of the decay $t \to cH^0$ in the framework of model III. Section 3 is devoted to discussion and our conclusions.
2 The Flavor changing $t \to cH^0$ decay in the framework of the general two Higgs Doublet model

The flavor changing transition $t \to cH^0$ is quite suppressed in the SM due to the Glashow-Iliopoulos-Maiani (GIM) mechanism [11]. The extended Higgs sector could bring large contributions to this decay and make CP violation possible, in general. This section is devoted to the calculation of the $BR$ and the CP violating asymmetry of the decay under consideration, in the general two Higgs doublet model, so called model III. In the model III, the flavor changing neutral currents in the tree level are permitted and various new parameters, such as Yukawa couplings, masses of new Higgs bosons, exist.

The $t \to cH^0$ process is controlled by the Yukawa interaction and in the model III, it reads as

$$L_Y = \eta^U_{ij} \bar{Q}_{iL} \phi_1 U_{jR} + \eta^D_{ij} \bar{Q}_{iL} \phi_2 D_{jR} + \xi^U_{ij} \bar{Q}_{iL} \phi_2 U_{jR} + \xi^D_{ij} \bar{Q}_{iL} \phi_2 D_{jR} + h.c. , \quad (1)$$

where $L$ and $R$ denote chiral projections $L(R) = 1/2(1 \mp \gamma_5)$, $\phi_i$ for $i = 1, 2$, are the two scalar doublets, $\bar{Q}_{iL}$ are left handed quark doublets, $U_{jR}(D_{jR})$ are right handed up (down) quark singlets, with family indices $i, j$. The Yukawa matrices $\eta^U_{ij}$ and $\eta^D_{ij}$ have in general complex entries. It is possible to collect SM particles in the first doublet and new particles in the second one by choosing the parametrization for $\phi_1$ and $\phi_2$ as

$$\phi_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + H^0 \end{pmatrix} + \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2} \chi^+ \\ i\chi^0 \end{pmatrix} ; \phi_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2} H^+ \\ H_0 + iH_2 \end{pmatrix} . \quad (2)$$

with the vacuum expectation values,

$$< \phi_1 > = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix} ; < \phi_2 > = 0 , \quad (3)$$

Here, $H_1$ and $H_2$ are the mass eigenstates $h^0$ and $A^0$ respectively since no mixing occurs between two CP-even neutral bosons $H^0$ and $h^0$ at tree level, for our choice.

The Flavor Changing (FC) interaction can be obtained as

$$L_{Y,FC} = \xi^U_{ij} \bar{Q}_{iL} \phi_2 U_{jR} + \xi^D_{ij} \bar{Q}_{iL} \phi_2 D_{jR} + h.c. , \quad (4)$$

where the couplings $\xi^U, D$ for the FC charged interactions are

$$\xi^U_{ch} = \xi^U_N V_{CKM} ,$$

$$\xi^D_{ch} = V_{CKM} \xi^D_N . \quad (5)$$
and $\xi_{N}^{U,D}$ is defined by the expression

$$\xi_{N}^{U(D)} = (V_{R(L)}^{U(D)})^{-1} \xi U_{L(R)}^{U(D)}.$$  

Here the index ”N” in $\xi_{N}^{U,D}$ denotes the word ”neutral”.

The SM contribution to the $BR$ of the process $t \to cH^0$ is negligibly small, which is at the order of the magnitude $10^{-13}$. Therefore, we take into account only the new effects beyond the SM. The relevant diagrams are given in Fig [1]. At this stage, we would like to discuss the possibilities not to take into account the tree level contribution to the decay under consideration, in the model III. First, it can be assumed that all the off diagonal neutral Yukawa couplings vanish and therefore the coupling $\xi_{N,tc}$ vanishes. Another possibility is to take the mixing between two neutral Higgs bosons $H^0$ and $h^0$ is small and the tree level interaction $t - c - H^0$ is negligible. In our case, we consider the gauge and $CP$ invariant Higgs potential which spontaneously breaks $SU(2) \times U(1)$ down to $U(1)$ as:

$$V(\phi_1, \phi_2) = c_1(\phi_1^+\phi_1 - v^2/2)^2 + c_2(\phi_2^+\phi_2)^2 + c_3[(\phi_1^+\phi_1 - v^2/2) + \phi_2^+\phi_2]^2 + c_4[(\phi_1^+\phi_1) - (\phi_2^+\phi_2)] + c_5[Re(\phi_1^+\phi_2)]^2 + c_6[Im(\phi_1^+\phi_2)]^2 + c_7. \quad (7)$$

Since we assume that only $\phi_1$ has vacuum expectation value, no mixing occurs between two neutral Higgs bosons and the tree level interaction vanishes. Furthermore, since we take the $c$-quark mass zero and the coupling $\xi_{N,tc}$ negligible compared to the couplings $\xi_{N,tt}$ and $\xi_{N,bb}$ (see [12]), the main contribution comes from the diagrams with internal charged Higgs boson and for the matrix element, we get

$$M(t \to cH^0) = -i V_{cb} V_{tb}^{*} \frac{g}{64 \pi m_{W}^{2}} (F^{(vert)} + F^{(self)}) \tilde{c} (1 + \gamma_{5}) t, \quad (8)$$

where

$$F^{(vert)} = \xi_{N,bb}^{D} (m_b \xi_{N,tt}^{U} f_1 + m_t \xi_{N,bb}^{D} f_2),$$

$$F^{(self)} = m_b \xi_{N,bb}^{U} \xi_{N,tt}^{U} f_3, \quad (9)$$

and the functions $f_1, f_2, f_3$ are defined as

$$f_1 = \int_{0}^{1} dx \int_{0}^{1-x} dy \left\{ 1 + \frac{z_t (-1 + x + y) (y + x z_t)}{x + g(x,y)} + \frac{y_{W} (2 - \frac{1}{\cos^{2} \theta_{W}})}{1 - x + g(x,y)} + 2 \ln (x + g(x,y)) \right\},$$

$$f_2 = \int_{0}^{1} dx \int_{0}^{1-x} dy \frac{y_{W} (-1 + x + y) (2 - \frac{1}{\cos^{2} \theta_{W}})}{1 - x + g(x,y)},$$

$$f_3 = \frac{1 - y_{b} + y_{b} \ln y_{b}}{1 - y_{b}}, \quad (10)$$
with $g(x, y) = (-1 + x + y)(x y_t + y z_t)$. Here $y_t = m_t^2/m_{H^\pm}$, $z_t = m_{H^0}/m_{H^\pm}$, $y_W = m_W^2/m_{H^\pm}$ and $y_b = m_b^2/m_{H^\pm}$. Using the eq. (8), it is straightforward to obtain the decay width as

$$\Gamma(t \to cH^0) = \frac{1}{32 \pi} \frac{y_t - z_t}{m_t y_t} |M|^2 .$$

(11)

Now we would like to give the expression for $A_{CP}$ of the above process. Here, we take $\xi_{N,bb}$ and $\xi_{N,tt}$ complex with the parametrizations

$$\xi_{N,tt}^U = |\xi_{N,tt}^U|^e^{i\theta_{tt}} ,$$

$$\xi_{N,bb}^D = |\xi_{N,bb}^D|^e^{i\theta_{tb}} ,$$

(12)

and assume that the complexity of $\xi_{N,tt}^U$ is small. Using the definition of the CP violating asymmetry $A_{CP}$

$$A_{CP} = \frac{\Gamma(t \to cH^0) - \Gamma(\bar{t} \to \bar{c}H^0)}{\Gamma(t \to cH^0) + \Gamma(\bar{t} \to \bar{c}H^0)}$$

(13)

we get

$$A_{CP} = |\xi_{N,tt}^U|^\sin(\theta_{tb} - \theta_{tt}) \frac{N}{D} ,$$

(14)

where

$$N = -2 \text{Im} \left( f_1 f_2^* + f_3 f_2 \right) ,$$

$$D = \frac{m_t}{m_b} y_W |\xi_{N,bb}^D|^2 + 2 |\xi_{N,tt}^U|^\text{Re} \left( f_1 f_2^* - f_3 f_2 \right) \cos(\theta_{tb} - \theta_{tt}) ,$$

(15)

and the functions $f_1$, $f_2$ and $f_3$ are given in eq. (10). Here the symbol $*$ denotes the complex conjugation. As it is shown from the eq. (14), $A_{CP}$ vanishes when two CP violating angles $\theta_{tb}$ and $\theta_{tt}$ are equal. This is interesting, since $A_{CP}$ can vanish even in the existence of complex phases, in the model III.

3 Discussion

In this section, we study the $\sin \theta_{tb}$, $m_{H^\pm}$ and $\xi_{N,bb}^D$ dependencies of the $BR$ and $A_{CP}$ for the process $t \to cH^0$, in the model III. For the calculation of the $BR$ we take the value of the total decay width $\Gamma_T \sim \Gamma(t \to bW)$ as $\Gamma_T = 1.55 \text{GeV}$. Notice that the coupling $\xi_{N,bb}^D$ is defined as $\xi_{N,ij}^{U(D)} = \sqrt{\frac{\mu}{\sqrt{2}}} \xi_{N,ij}^{U(D)}$.

The process $t \to cH^0$ exists also in the SM and model II (or I) version of the 2HDM. In both models this process appears at least at loop level. In the SM model internal mediating $W^\pm$
bosons are responsible for this decay and its BR is very small, at the order of the magnitude of $10^{-13}$. In the model II, additional contribution comes from the charged Higgs boson $H^\pm$ and it can be enhanced compared to the SM result by playing with the free parameter $\tan\beta$, respecting the experimental measurements. However, no $A_{CP}$ occurs in the model II (I) and also in the SM. This forces one to go into the model III, with complex and possibly large Yukawa couplings.

Model III contains large number of free parameters such as Yukawa couplings, $\tilde{\xi}^{U(D)}_{N,ij}$, the masses of new Higgs bosons, $H^\pm$, $h^0$ and $A^0$, and they should be restricted by using experimental measurements. At this stage we summarize these restrictions:

- We neglect all the Yukawa couplings except $\tilde{\xi}^{U}_{N,tt}$ and $\tilde{\xi}^{D}_{N,bb}$ since they are negligible due to their light flavor contents, by our assumption. Notice that we also neglect the off diagonal coupling $\tilde{\xi}^{U}_{N,tc}$, since it is smaller compared to $\tilde{\xi}^{U}_{N,tt}$ (see [12]). Therefore, the new neutral Higgs bosons do not have any contribution to the BR of the decay under consideration.

- We take $\tilde{\xi}^{U}_{N,tt}$ and $\tilde{\xi}^{D}_{N,bb}$ complex and respect the constraint for the angle $\theta_{tt}$ and $\theta_{tb}$, due to the experimental upper limit of neutron electric dipole moment, $d_n < 10^{-25}$ e·cm, which leads to $\frac{1}{m_t m_b} Im (\tilde{\xi}^{U}_{N,tt} \tilde{\xi}^{D}_{N,bb}) < 1.0$ for $M_{H^\pm} \approx 200$ GeV [13].

- We find a constraint region for these free parameters by restricting the Wilson coefficient $C_7^{eff}$, which is the effective coefficient of the operator $O_7 = \frac{\bar{s}_\alpha \sigma_{\mu\nu} (m_b R + m_s L) b_\alpha F^{\mu\nu}}{16 \pi^2}$ (see [12] and references therein), in the region $0.257 \leq |C_7^{eff}| \leq 0.439$. Here upper and lower limits were calculated using the CLEO measurement [14].

\[ BR(B \to X_s \gamma) = (3.15 \pm 0.35 \pm 0.32) \times 10^{-4} . \]  

(16)

and all possible uncertainties in the calculation of $C_7^{eff}$ [12].

For completeness we present the Wilson coefficient $C_7^{eff}$. Denoting the contribution for the SM with $C_7^{SM}(m_W)$ and the additional charged Higgs contribution with $C_7^H(m_W)$, we have the initial values

\[
C_7^{2HDH}(m_W) = C_7^{SM}(m_W) + \frac{1}{m_t^2} (\tilde{\xi}^{U}_{N,tt} + \tilde{\xi}^{D}_{N,tc} V^*_{ts} V^*_{tb}) (\tilde{\xi}^{U}_{N,tt} + \tilde{\xi}^{D}_{N,tc} V^*_{tb}) F_1(y_t),
\]

\[
+ \frac{1}{m_t m_b} (\tilde{\xi}^{U}_{N,tt} + \tilde{\xi}^{U}_{N,tc} V^*_{ts} V^*_{ts}) (\tilde{\xi}^{D}_{N,bb} + \tilde{\xi}^{D}_{N,bs} V^*_{ts} V^*_{tb}) F_2(y_t),
\]

(17)

The LO corrected coefficient $C_7^{2HDH}(\mu)$ is given as

\[
C_7^{LO,2HDH}(\mu) = \eta^{16/23} C_7^{2HDH}(m_W) + \frac{1}{3}(\eta^{14/23} - \eta^{16/23}) C_8^{2HDH}(m_W)
+ C_2^{2HDH}(m_W) \sum_{i=1}^{8} h_i \eta^a_i ,
\]  

(18)
and \( \eta = \alpha_s(m_W)/\alpha_s(\mu) \), \( h_i \) and \( a_i \) are the numbers which appear during the evaluation \cite{15}. The explicit forms of the functions \( F_{1(2)}(y) \) are,

\[
F_1(y) = \frac{y(7 - 5y - 8y^2)}{72(y - 1)^3} + \frac{y^2(3y - 2)}{12(y - 1)^4} \ln y,
\]

\[
F_2(y) = \frac{y(5y - 3)}{12(y - 1)^2} + \frac{y(-3y + 2)}{6(y - 1)^3} \ln y.
\]

The discussion given above allows us to obtain a constraint region for the couplings \( \xi_{N,tt}^U \), \( \xi_{N,bb}^D \) and the CP violating parameters, \( \sin \theta_{tt} \) and \( \sin \theta_{bb} \). Here, we assume that the coupling \( \xi_{N,tt}^U \) has a small imaginary part and we choose \( |r_{tb}| = |\xi_{N,bb}^U| < 1 \). Notice that, in figures, the BR is restricted in the region between solid (dashed) lines for \( C_7^{eff} > 0 \) (\( C_7^{eff} < 0 \)). Here, there are two possible solutions for \( C_7^{eff} \) due to the cases where \( |r_{tb}| < 1 \) and \( r_{tb} > 1 \). In the case of complex Yukawa couplings, only the solutions obeying \( |r_{tb}| < 1 \) exist.

In Fig. 2, we plot the BR with respect to \( \sin \theta_{tb} \) for \( \sin \theta_{tt} = 0.1 \), \( m_{H^\pm} = 400 \text{ GeV} \), \( m_{H^0} = 120 \text{ GeV} \), \( \xi_{N,bb}^D = 10 \text{ m}_b \). As shown in this figure, the BR can reach to the values at the order of the magnitude of \( 10^{-7} \) and it is not so much sensitive to the parameter \( \sin \theta_{tb} \). Its magnitude is almost 30% larger for \( C_7^{eff} > 0 \) compared to the one for \( C_7^{eff} < 0 \).

Fig. 3 represents the BR with respect to \( |\xi_{N,bb}^D| \) for \( \sin \theta_{tt} = 0.1 \), \( \sin \theta_{tb} = 0.5 \), \( m_{H^\pm} = 400 \text{ GeV} \) and \( m_{H^0} = 120 \text{ GeV} \). This figure shows that the BR is strongly sensitive to the coupling \( |\xi_{N,bb}^D| \) and it can get the values at the order of \( 10^{-6} \) even for \( |\xi_{N,bb}^D| = 20 \text{ m}_b \). This observation is an important clue about the upper limit of the coupling \( |\xi_{N,bb}^D| \), with the possible future measurement of the BR. For the small coupling \( |\xi_{N,bb}^D| \), the restricted region for the BR becomes narrow, for both \( C_7^{eff} > 0 \) and \( C_7^{eff} < 0 \).

Finally, we show the \( m_{H^0} \) dependence of the BR in Fig. 4 for \( \sin \theta_{tt} = 0.1 \), \( \sin \theta_{tb} = 0.5 \), \( m_{H^\pm} = 400 \text{ GeV} \) and \( |\xi_{N,bb}^D| = 10 \text{ m}_b \). With the increasing values of \( m_{H^0} \), the BR decreases and the restriction region becomes narrower.

At this stage, we would like to analyse the CP asymmetry \( A_{CP} \) of the decay \( t \to cH^0 \) and show \( \sin \theta_{tb} \) and \( m_{H^0} \) dependencies of \( A_{CP} \) in the figures 5 and 6, respectively. \( A_{CP} \) is at the order of the magnitude of \( 10^{-2} \) for the intermediate values of \( \sin \theta_{tb} \) and it can reach to \( 7 \times 10^{-2} \) for \( C_7^{eff} > 0 \). Notice that \( \sin \theta_{tt} \) is taken small and \( A_{CP} \) vanishes when two CP parameters have the same values, namely \( \sin \theta_{tb} = \sin \theta_{tt} \). If \( A_{CP} \) is positive (negative), \( C_7^{eff} \) can have both signs. However, if it is negative, \( C_7^{eff} \) must be negative. This observation is useful in the determination of the sign of \( C_7^{eff} \). The same behaviour is observed in Fig. 6 which represents the mass \( m_{H^0} \) dependence of \( A_{CP} \). When the Higgs mass \( m_{H^0} \) increases, an enhancement in \( A_{CP} \) is detected, especially for \( C_7^{eff} > 0 \).
Now we will summarize our results:

- The $BR$ of the flavor changing process $t \rightarrow cH^0$ is at the order of $10^{-13}$ in the SM and the extended Higgs sector brings large contributions, at the order of $10^{-7} - 10^{-6}$, which can be measured in the future experiments. This ensures a crucial test for the new physics beyond the SM.

- The $BR$ is sensitive to $|\xi_{N,bb}^D|$ and its measurement makes it possible to predict an upper limit for this coupling. Furthermore, the measurement of the $BR$ of the decay under consideration can give important information about the mass of Higgs boson $H^0$.

- $A_{CP}$ is at the order of the magnitude of $10^{-2}$ for the intermediate values of $\sin \theta_{tb}$ and it rises up to the values $7 \times 10^{-2}$ for $C_{t}^{eff} > 0$. The measurement of $A_{CP}$ can ensure a hint for the determination the sign of $C_{t}^{eff}$.

Therefore, the experimental investigation of the process $t \rightarrow cH^0$ will be effective for understanding the physics beyond the SM.
