Abstract

Let \((M, g)\) be a pseudo Riemannian manifold. We consider four geometric structures on \(M\) compatible with \(g\): two almost complex and two almost product structures satisfying additionally certain integrability conditions. For instance, if \(r\) is a product structure and symmetric with respect to \(g\), then \(r\) induces a pseudo Riemannian product structure on \(M\). Sometimes the integrability condition is expressed by the closedness of an associated two-form: if \(j\) is almost complex on \(M\) and \(\omega(x, y) = g(jx, y)\) is symplectic, then \(M\) is almost pseudo Kähler. Now, product, complex and symplectic structures on \(M\) are trivial examples of generalized (para)complex structures in the sense of Hitchin. We use the latter in order to define the notion of interpolation of geometric structures compatible with \(g\). We also compute the typical fibers of the twistor bundles of the new structures and give examples for \(M\) a Lie group with a left invariant metric.

Keywords: generalized complex structure; interpolation; Kähler; symplectic; signature; twistor bundle

1 Introduction

Generalized complex geometry includes as special cases complex and symplectic geometries. It was introduced by Nigel Hitchin in [14] in 2003 and further developed by Marco Gualtieri [11] and Gil Cavalcanti. Since then it has greatly expanded, with a significant impact in Mathematical Physics. The paracomplex analogue was studied by Aïssa Wade [20].

The article [18] deals with similar ideas, now starting not just from a smooth manifold, but from a manifold which is already endowed with a structure, and working out a notion of interpolation of supplementary compatible geometric structures. More precisely, given a complex manifold \((M, j)\), six families of distinguished generalized complex or paracomplex structures were defined and studied on \(M\). Each one of them interpolates between two geometric structures on \(M\) compatible with

*Partially supported by CONICET, FONCyT, SECyT (UNC).
$j$, for instance, between totally real foliations and Kähler structures, or between hypercomplex and $\mathbb{C}$-symplectic structures. In the same article, a similar analysis was carried out for a symplectic manifold $(M, \omega)$. One had for instance the notion of a structure generalizing $\mathbb{C}$-symplectic structures and bi-Lagrangian foliations (both compatible with $\omega$).

The purpose of this note is to obtain analogous results, but now starting from a pseudo Riemannian manifold $(M, g)$. As a by-product, we note that the search for nontrivial examples for this new structure can bring about a better understanding of some manifolds, in the same way, for instance, that generalized complex structures shed light on the geometry of nil- and solvmanifolds [6, 3].

In Section 2 we recall the definitions and properties of generalized complex or paracomplex structures. In Subsection 2.2 we consider geometric structures on $M$ compatible with $g$, which we call integrable $(\lambda, 0)$- or $(0, \ell)$-structures, with $\lambda, \ell = \pm 1$; for instance, $\lambda = -1$ and $\ell = -1$ give us anti-Hermitian and almost pseudo Kähler structures, respectively. This nomenclature will allow us to define families of generalized complex or paracomplex structures on $M$, called integrable $(\lambda, \ell)$-structures, which in a certain sense, specified in Theorem 3.6, interpolate between integrable $(\lambda, 0)$- and $(0, \ell)$-structures on $M$. In Section 4 we give explicitly the typical fibers of the associated twistor bundles. The last section is devoted to examples: We give a curve of integrable $(1, -1)$-structures on the manifold of ellipses endowed with a homogeneous Riemannian metric, joining a Kähler structure with a Riemannian product structure. Also, we find compatible integrable $(-1,-1)$-structures on certain 6-dimensional pseudo Riemannian nilmanifolds, although they do not admit the extremal integrable $(-1,0)$- and $(0,-1)$-structures (all in the left invariant context).

2 Preliminaries

2.1 Generalized complex and paracomplex structures

We recall from the seminal work [11] the definitions and basic facts on generalized complex structures, and on generalized paracomplex structures from [20]. A unified approach can be found in [19].

Let $M$ be a smooth manifold (by smooth we mean of class $C^\infty$; all the objects considered will belong to this class). The extended tangent bundle is the vector bundle $\mathbb{T}M = TM \oplus T^*M$ over $M$. A canonical split pseudo Riemannian structure on $\mathbb{T}M$ is defined by

$$b(u + \sigma, v + \tau) = \tau(u) + \sigma(v),$$

for smooth sections $u + \sigma, v + \tau$ of $\mathbb{T}M$. The Courant bracket of these sections [5] is given by

$$[u + \sigma, v + \tau] = [u, v] + \mathcal{L}_u \tau - \mathcal{L}_v \sigma - \frac{1}{2} d (\tau(u) - \sigma(v)),$$

where $\mathcal{L}$ denotes the Lie derivative.

A real linear isomorphism $S$ with $S^2 = \lambda \text{id}$, $\lambda = \pm 1$, is called split if $\text{tr} \ S = 0$ (equivalently, if the dimension of the $\pm \sqrt{\lambda}$-eigenspaces of $S$ coincide); this is always the case if $\lambda = -1$.

For $\lambda = \pm 1$, let $S$ be a smooth section of $\text{End} \ (\mathbb{T}M)$ satisfying

$$S^2 = \lambda \text{id}, \ S \text{ is split and skew-symmetric for } b$$

(2)
and such that the set of smooth sections of the $\pm \sqrt{\lambda}$-eigenspace of $S$ is closed under the Courant bracket (if $\lambda = -1$, this means as usual closedness under the $\mathbb{C}$-linear extension of the bracket to sections of the complexification of $TM$). Then, for $\lambda = -1$ (respectively, $\lambda = 1$), $S$ is called a generalized complex (respectively, generalized paracomplex) structure on $M$. Notice that in [20] the latter is not required to be split.

We also have the notion of a $\text{(+)}$-generalized paracomplex structure $S$. It is the same as a generalized paracomplex structure, but closedness under the Courant bracket is required only for sections of the 1-eigendistributions of $S$.

### 2.2 Geometric structures compatible with a pseudo Riemannian metric

Let $(M, g)$ be a pseudo Riemannian manifold. We consider the following integrable geometric structures on $M$ compatible with $g$. Basically, they are rotations and reflections in each tangent space of $M$ which are isometries or anti-isometries for $g$ and satisfy certain integrability conditions. The reason of the names integrable $(\lambda, 0)$- or $(0, \ell)$-structures will become apparent in Theorem 3.6.

A product structure on the smooth manifold $M$ is a tensor field $r$ of type $(1, 1)$ on $M$ with $r^2 = \text{id}$ such that the eigendistributions $D(\delta)$ of eigenvalues $\delta = \pm 1$ are integrable. Notice that the cases $r = \pm \text{id}$ are trivial. If $\dim D(-1) = \dim D(1)$, then the product structure $r$ is called a paracomplex structure.

**Pseudo Riemannian product structure on $(M, g)$** [21]. It is given by a product structure $r$ on $M$ symmetric with respect to $g$ (or equivalently, $r$ is an isometry of $g$).

Equivalently, it is given by an ordered pair of orthogonal nondegenerate foliations (nondegenerate means that the restriction of $g$ to the leaves is nondegenerate). The leaves of the respective foliations are the integral submanifolds of the distributions $D(1)$ and $D(-1)$. Using the properties of $r$ we have that $D(1)$ and $D(-1)$ are orthogonal, and hence nondegenerate, since they intersect only at zero.

We call this structure an **integrable $(1, 0)$-structure** on $(M, g)$.

**Anti-Hermitian structure on $(M, g)$** [4, 16]. It is given by a complex structure $j$ on $M$ which is symmetric with respect to $g$.

In this case, $g$ has necessarily neutral signature, since $j$ turns out to be a linear anti-isometry of $g$ and so it sends space-like tangent vectors to time-like tangent vectors. If $j$ is additionally parallel, then $(M, g, j)$ is called an anti-Kähler manifold.

We call this structure an **integrable $(-1, 0)$-structure** on $(M, g)$.

**Almost para-Kähler structure on $(M, g)$**. It is given by a symplectic form $\omega$ on $M$ such that $r^2 = \text{id}$, where $r$ is the unique tensor field satisfying $\omega(\cdot, \cdot) = g(r\cdot, \cdot)$.

One has that the tensor field $r$ is skew-symmetric for $g$. The eigendistributions of $r$ are null for $g$ and Lagrangian for $\omega$, hence $r$ is split and $g$ has neutral signature, since the dimension of a null subspace of a Euclidean space of signature $(p, q)$ is less than or equal to $\min (p, q)$ (Proposition 2.45 in [12]). In the terminology of [13] this structure would be an almost Kähler $\mathbb{D}$-manifold. If additionally the eigendistributions of $r$ are integrable, we have a bi-Lagrangian foliation [9].

We call this structure an **integrable $(0, 1)$-structure** on $(M, g)$.

**Almost pseudo Kähler structure on $(M, g)$**. It is given by a symplectic form $\omega$ on $M$ such that $j^2 = -\text{id}$, where $j$ is the unique tensor field satisfying $\omega(\cdot, \cdot) = g(j\cdot, \cdot)$. 

3
The tensor field $j$ is skew-symmetric and also a linear isometry for $g$. Hence, $g$ must have even signature. If $j$ is additionally a complex structure, then $(M, g, j)$ is a pseudo Kähler manifold.

We call this structure an **integrable** $(0, -1)$-structure on $(M, g)$.

**Nondegenerate foliation** on $(M, g)$. It is given by a tensor field $r$ of type $(1, 1)$ symmetric with respect to $g$, with $r^2 = \text{id}$, such that $D(1)$ is integrable. The non-degeneracy refers to the fact that $g$ induces a pseudo Riemannian metric on the leaves.

We call this structure an **integrable** $(1, 0)$-structure on $(M, g)$.

### 3 Generalized geometric structures on pseudo Riemannian manifolds

#### 3.1 Integrable $(\lambda, \ell)$-structures on $(M, g)$

Given a bilinear form $c$ on a real vector space $V$, let $c^\flat \in \text{End}(V, V^*)$ be defined by $c^\flat(u)(v) = c(u, v)$. The form $c$ is symmetric (respectively, skew-symmetric) if and only if $(c^\flat)^* = c^\flat$ (respectively, $(c^\flat)^* = -c^\flat$).

A paracomplex structure $r$ on a vector bundle $E \to M$, $E \neq TM$, over a smooth manifold $M$ is a smooth tensor field of type $(1, 1)$ on $E$ satisfying $r^2 = \text{id}$ and that $r_p$ is split for any $p \in M$.

**Definition 3.1** Let $(M, g)$ be a pseudo Riemannian manifold. For $k = -1$ or $k = 1$, let $I_k$ be the complex, respectively paracomplex structure on $TM$ given by

$$I_k = \begin{pmatrix} 0 & k(g^\flat)^{-1} \\ g^\flat & 0 \end{pmatrix}.$$  

**Remark 3.2** For further reference we verify that $I_k$ is symmetric for $b$ defined in [1]. It suffices to check that $g^\flat(u)(v) = g^\flat(v)(u)$ for all vector fields $u, v$ on $M$ and $\tau \left( (g^\flat)^{-1}(\sigma) \right) = \sigma \left( (g^\flat)^{-1}(\tau) \right)$ for all one forms $\sigma, \tau$ on $M$. Both assertions follow from the symmetry of $g$ (for the second one, use the fact that $\sigma = g^\flat(x)$ and $\tau = g^\flat(y)$ for some vector fields $x, y$ on $M$).

Now we introduce four families of generalized geometric structures on $(M, g)$ interpolating between some of the structures listed in the previous section.

**Definition 3.3** Let $(M, g)$ be a pseudo Riemannian manifold. Given $\lambda = \pm 1$ and $\ell = \pm 1$, a generalized complex structure $S$ (for $\lambda = -1$) or a generalized paracomplex structure $S$ (for $\lambda = 1$) on $M$ is said to be an **integrable** $(\lambda, \ell)$-structure on $(M, g)$ if

$$SI_k = -I_k S,$$  

where $k = -\lambda \ell$.

We call $\mathcal{S}_g(\lambda, \ell)$ the set of all integrable $(\lambda, \ell)$-structures on $(M, g)$. 

3
Example 3.4 If $s$ and $\omega$ are integrable $(\lambda, 0)$- and $(0, \ell)$-structures on $(M, g)$, respectively, then easy computations show that

$$R = \begin{pmatrix} s & 0 \\ 0 & -s^* \end{pmatrix} \quad \text{and} \quad Q = \begin{pmatrix} 0 & \lambda(\omega^b)^{-1} \\ \omega^b & 0 \end{pmatrix}$$

belong to $\mathcal{S}_g(\lambda, \ell)$. They are well known to be generalized complex or paracomplex structures on $M$. In order to verify (3) notice for instance that $s$ is symmetric for $g$ if and only if $g^b \circ s = s^* \circ g^b$ and that $r$ and $j$ are as in the definitions of integrable $(0, 1)$- and $(0, -1)$-structures if and only if $(\omega^b)^{-1} \circ g^b = \ell(g^b)^{-1} \circ \omega^b$.

Remark 3.5 Analogously as in [18], one can define $(\pm, \ell)$-integrable $(1, \ell)$-structures on $(M, g)$, for $\ell = \pm 1$.

The following simple theorem, along with Theorem 4.1 below, contributes to render the notion of an integrable $(\lambda, \ell)$-structure (Definition 3.3) appropriate and relevant.

Theorem 3.6 Let $(M, g)$ be a pseudo Riemannian manifold. For $\lambda = \pm 1, \ell = \pm 1$, integrable $(\lambda, \ell)$-structures on $(M, g)$ interpolate between integrable $(\lambda, 0)$- and $(0, \ell)$-structures on $(M, g)$, that is, if

$$R = \begin{pmatrix} s & 0 \\ 0 & t \end{pmatrix} \quad \text{and} \quad Q = \begin{pmatrix} 0 & p \\ \omega^b & 0 \end{pmatrix}$$

belong to $\mathcal{S}_g(\lambda, \ell)$, then $s$ and $\omega$ are integrable $(\lambda, 0)$- and $(0, \ell)$-structures on $(M, g)$, respectively.

Proof We call $q = \omega^b$. It is well known from [11] and [20] (see also [19]) that if $R$ and $Q$ as above are both generalized complex (respectively paracomplex) structures, then $s$ is a complex or a product structure on $M$ and $\omega$ is a closed 2-form. Also, that $t = -s^*$ and $p = -q^{-1}$ (respectively, $p = q^{-1}$).

Now, since $R$ and $Q$ anti-commute with $I_k$ ($k = -\lambda \ell$), one has that $g^b \circ s = s^* \circ g^b$ and $(\omega^b)^{-1} \circ g^b = \ell(g^b)^{-1} \circ \omega^b$, and so, by the equivalent statements in Example 3.4 we have that $s$ and $\omega$ are integrable $(\lambda, 0)$- and $(0, \ell)$-structures, respectively. \[\qed\]

3.2 Integrable $(\lambda, \ell)$-structures on $(M, g)$ in classical terms

Proposition 3.7 An integrable $(\lambda, \ell)$-structure $S$ on a pseudo Riemannian manifold $(M, g)$ has the form

$$S = \begin{pmatrix} A & \lambda B(g^b)^{-1} \\ g^b B & -A^* \end{pmatrix}$$

where $A$ and $B$ are endomorphisms of $TM$ satisfying

$$\lambda A^2 + \ell B^2 = id, \quad AB - BA = 0, \quad g^b A = A^* g^b.$$

Proof For a bilinear map $\pi : V^* \times V^* \to \mathbb{R}$, let $\pi^z : V^* \to V$ be defined by $\eta(\pi^z(\xi)) = \pi(\xi, \eta)$, for all $\xi, \eta \in V^*$. 

5
Since $S$ is a generalized complex (for $\lambda = -1$) or paracomplex structure (for $\lambda = 1$), by [7] (see also [19]) one has

$$S = \begin{pmatrix} A & \pi^2 \\ \theta^\flat & -A^* \end{pmatrix},$$

where $\theta$ and $\pi$ are skew-symmetric, and $A$ satisfies

$$A^2 + \pi^2 \theta^\flat = \lambda \text{id}, \quad \theta^\flat A = A^* \theta^\flat, \quad \text{and} \quad \pi^2 A^* = A \pi^2.$$  \hfill (5)

Now, as $S$ anti-commutes with $I_k$, we have that

$$g^\flat \pi^2 = \lambda \ell B (g^\flat)^{-1} \quad \text{and} \quad g^\flat A = A^* g^\flat.$$ \hfill (7)

By putting $B = (g^\flat)^{-1} \theta^\flat$, we have $\pi^2 = \lambda B (g^\flat)^{-1}$ and so (7) holds. Now $\theta^\flat A = A^* \theta^\flat$ and $g^\flat A = A^* g^\flat$ yield $AB - BA = 0$. Finally, from $A^2 + \pi^2 \theta^\flat = \lambda \text{id}$ and $\pi^2 \theta^\flat = \lambda \ell B^2$, we obtain $\lambda A^2 + \ell B^2 = \text{id}$. \hfill

M. Crainic obtained in [7] (see also [19]) conditions on $A, \theta$ and $\pi$ for $S$ as in (5) to be Courant integrable. One can deduce conditions on $A$ and $B$ as in [14] for the integrability of $S$.

### 3.3 A signature associated to integrable $(1, 1)$-structures on $(M, g)$

**Proposition 3.8** Let $S$ be an integrable $(1, 1)$-structure on a pseudo Riemannian manifold $(M, g)$ of dimension $m$. Then the form $\beta_S$ on $TM$ defined by

$$\beta_S (x, y) = b (SI_- x, y)$$

is symmetric and has signature $(2n, 2m - 2n)$ for some integer $n$ with $0 \leq n \leq m$.

**Proof** The form $\beta_S$ is symmetric since $S$ and $I_{-1}$ anti-commute and are skew-symmetric and symmetric for $b$ (see Remark 3.2), respectively.

We have that $(SI_{-1})^2 = \text{id}$. Let $D(\pm 1)$ be the $\pm 1$-eigendistribution of $SI_{-1}$. We verify that $I_{-1} (D(1)) = D(-1)$, so $D(1)$ and $D(-1)$ have both dimension $m$. Let $b^\pm = b|_{D(\pm 1) \times D(\pm 1)}$ and $\beta^\pm = \beta_S|_{D(\pm 1) \times D(\pm 1)}$. We compute that $b^\pm|_{D(1) \times D(-1)} \equiv 0$; in particular, by the orthogonality lemma (2.30 in [12]), $b^\pm$ is nondegenerate. Suppose that $b^+$ has signature $(n, m - n)$. Hence $b^-$ has signature $(m - n, n)$ ($b$ is split). On the other hand, we compute also that $b^\pm = \pm \beta^\pm$. Therefore the signature of $\beta_S$ is $(2n, 2m - 2n)$, as desired. \hfill

**Definition 3.9** An integrable $(1, 1)$-structure $S$ on $(M, g)$ as above is called an **integrable $(1, 1; n)$-structure**, and we write $\text{sig} (S) = n$.

The next proposition explains the meaning of $\text{sig} (S)$ for an extremal integrable $(1, 1)$-structure on $M$ as in Example 3.4.

**Proposition 3.10** a) Let $r$ be an integrable $(1, 0)$-structure on $(M, g)$ and suppose that the metrics induced on $D(1)$ and $D(-1)$ have signatures $(p_+, q_+)$ and $(p_-, q_-)$, respectively. Then

\[ R = \begin{pmatrix} r & 0 \\ 0 & -r^* \end{pmatrix} \]
is an integrable \((1, 1; p_+ + q_-)\)-structure on \((M, g)\).

b) Let \(\omega\) be an integrable \((0, 1)\)-structure on \((M, g)\). Then

\[
Q = \begin{pmatrix} 0 & (\omega^b)^{-1} \\ \omega^b & 0 \end{pmatrix}
\]

is an \((1, 1; \frac{2m}{2})\)-structure on \((M, g)\).

**Proof**

a) We compute

\[
\beta_R(u + \sigma, v + \tau) = -(g(r u, v) + \hat{g}(r^* \sigma, \tau)),
\]

where \(\hat{g}\) is the symmetric bilinear form on \(T^*M\) defined by

\[
\hat{g}(\alpha, \tau) = g((\omega^b)^{-1} \alpha, (\omega^b)^{-1} \tau).
\]

Let \(h\) be the nondegenerate bilinear form on \(TM\) given by \(h(\cdot, \cdot) = g(\cdot, \cdot)\). Note that the signature of \(\beta_R\) is twice the signature of \(h\), hence we compute the signature of \(h\). Now, \(r^2 = id\) and the eigendistributions \(D(\pm 1)\) of \(r\) are orthogonal with respect to \(h\) and \(g\). The signature of \(h\) is equal to the sum of the signatures of \(h|_{D(1) \times D(1)}\) and \(h|_{D(-1) \times D(-1)}\) and it can be seen that these are \((p_+, q_+)\) and \((q_-, p_-)\), respectively. Then, the signature of \(h\) is \((p_+ + q_-, q_+ + p_-)\). Thus, \(\text{sig}(R) = p_+ + q_-\), as desired.

b) We compute

\[
\beta_Q(u + \sigma, v + \tau) = \hat{g}(\omega^b u, \tau) - g((\omega^b)^{-1} \sigma, v),
\]

where \(\hat{g}\) is as in a). Let \(\{u_1, \ldots, u_p, v_1, \ldots, v_q\}\) be a local orthonormal basis of \(TM\) with respect to \(g\) where \(u_i\) is space-like (for \(i = 1, \ldots, p\)) and \(v_j\) is time-like (for \(j = 1, \ldots, q\)). Let \(\{u^*_1, \ldots, u^*_p, v^*_1, \ldots, v^*_q\}\) be the dual basis of \(T^*M\) with respect to \(\omega\), i.e., \(u^*_i = \omega^b u_i\) and \(v^*_i = \omega^b v_i\). It is easy to check that \(\hat{g}(\omega^b u, \omega^b v) = -g(u, v)\), for all \(u, v \in TM\) and that

\[
\{v_1 + v^*_1, \ldots, v_q + v^*_q, u_1 - u^*_1, \ldots, u_p - u^*_p, v_1 - v^*_1, \ldots, v_q - v^*_q, u_1 + u^*_1, \ldots, u_p + u^*_p\}
\]

is an orthogonal basis of \(\beta_Q\) where the first \(p + q\) vectors fields are space-like and the remaining \(p + q\) vectors fields are time-like. \(\blacksquare\)

4 The \((\lambda, \ell)\)-twistor bundles over \((M, g)\)

Let \(\mathbb{L}\) denote the Lorentz numbers \(a + \varepsilon b\), \(\varepsilon^2 = 1\) and let \(V\) be a vector space over \(\mathbb{F} = \mathbb{R}, \mathbb{C}, \mathbb{L}\) or \(\mathbb{H}\), where \(\mathbb{H} = \mathbb{C} + j\mathbb{C}\) are the quaternions (we consider right vector spaces over \(\mathbb{H}\)). Let \(O(m, n)\) be the group of automorphisms of the symmetric form of the Euclidean space of signature \((m, n)\) and let \(SO^* (m)\) be the group of automorphisms of an anti-Hermitian form on \(\mathbb{H}^m\) (in [12] it is called \(SK(m, \mathbb{H})\)).

**Theorem 4.1** Let \((M, g)\) be a pseudo Riemannian manifold of dimension \(m\) and signature \((p, q)\). Then, integrable \((\lambda, \ell)\)-structures on \((M, g)\) are smooth sections of a fiber bundle over \(M\) with typical fiber \(G/H\), according to the following table.

| \(\lambda\) | \(\ell\) | \(\text{sig}\) | \(G\) | \(H\) |
|---|---|---|---|---|
| 1 | 1 | \(n\) | \(O(m, \mathbb{C})\) | \(O(n, m - n)\) |
| 1 | -1 | - | \(O(p, q) \times O(p, q)\) | \(O(p, q)\) |
| -1 | 1 | - | \(O(p, p) \times O(p, p)\) | \(O(p, p)\) |
| -1 | -1 | - | \(O(m, \mathbb{C})\) | \(SO^* (m)\) |
Let $D$ to $D$ we have $S$ notation, in the rest of the subsection we write $b$ and $I_k$ instead of $b_p$ and $(I_k)_p$.

Before proving the theorem we introduce some notation and present a proposition. Now we work at the algebraic level. We fix $p \in M$ and call $E = T_p M$. By abuse of notation, in the rest of the subsection we write $b$ and $I_k$ instead of $b_p$ and $(I_k)_p$.

Let $\sigma (\lambda, \ell)$ denote the set of all $S \in \text{End}_\mathbb{R} (E)$ satisfying

$$S^2 = \lambda \text{id}, S \text{ is split and skew-symmetric for } b \text{ and } SI_k = -I_k S \text{ with } k = -\lambda \ell.$$ Similarly, $\sigma (1, 1; n)$ consists, by definition, of the elements $S$ of $\sigma (1, 1)$ with $\text{sig} (S) = n$.

Note that $(E, I_k)$ is a vector space over $\mathbb{C}$ (respectively, $\mathbb{L}$) for $k = -1$ (respectively, $k = 1$) via $(a + ib) x = ax + b I_{-1} x$ (respectively, $(a + \varepsilon b) x = ax + b I_1 x$).

**Proposition 4.2** Let $b_{-1} : E \times E \to \mathbb{C}$ and $b_1 : E \times E \to \mathbb{L}$ be defined by

$$b_{-1} (x, y) = b (x, y) - ib (x, I_{-1} y) \quad \text{and} \quad b_1 (x, y) = b (x, y) + \varepsilon b (x, I_1 y).$$

Then $b_{-1}$ is $\mathbb{C}$-symmetric and $b_1$ is $\mathbb{L}$-symmetric (with respect to $I_{-1}, I_1$, respectively).

Also, if $S \in \text{End}_\mathbb{E} (E)$ satisfies $S^2 = \lambda \text{id}$ then $S \in \sigma (\lambda, \ell)$ if and only if

$$b_k (S x, S y) = -\lambda b_k (x, y)$$

for any $x, y \in E$ (where $k = -\lambda \ell$).

**Proof** Let us denote $\epsilon_1 = \varepsilon$ and $\epsilon_{-1} = i$ (in particular, $\epsilon_2^2 = k$). From Definition 3.1 and the fact that $I_k$ is symmetric for $b$ (see Remark 3.2) and $I_k^2 = \text{id}$ we have that, for $k = \pm 1$,

$$b_k (x, y) = b_k (y, x) \quad \text{and} \quad \epsilon_k b_k (x, y) = b_k (\epsilon_k x, y)$$

for all $x, y \in E$. Then the first assertion is true.

Now we prove the second assertion. Suppose first that $S \in \sigma (\lambda, \ell)$. We call $k = -\lambda \ell$. Since $S$ anti-commutes with $I_k$ and $S$ is skew-symmetric for $b$, we have

$$b_k (S x, S y) = b (S x, S y) + k \epsilon_k b (S x, I_k S y) = -b (S^2 x, y) - k \epsilon_k b (S x, S I_k y) = -b (S^2 x, y) + k \epsilon_k b (S^2 x, I_k y) = -\lambda b (x, y) + k \epsilon_k b (x, I_k y) = -\lambda (b (x, y) - k \epsilon_k b (x, I_k y)) = -\lambda b_k (x, y).$$

Conversely, suppose that $S^2 = \lambda \text{id}$ and (8) holds. Note that $b_k (S x, y) = -b_k (x, S y)$; it implies that

$$b (S x, y) = -b (x, S y) \quad \text{and} \quad b (S x, I_k y) = b (x, I_k S y).$$

From the first identity in (8), we have that $S$ is skew-symmetric for $b$. As a consequence of (8) and the nondegeneracy of $b$ we have that $-S I_k = I_k S$.

We complete the proof by showing that $S$ is split in the case $\lambda = 1$ ($S^2 = \text{id}$). Let $D(\delta)$ be the $\delta$-eigenspaces of $S$, with $\delta = \pm 1$, and consider the restriction of $I_k$ to $D(1)$. This restriction gives an isomorphism between $D(1)$ and $D(-1)$ (and hence they have the same dimension). Indeed, if $v \in D(\pm 1)$, as $S$ anti-commutes with $I_k$, we have $S (I_k v) = -I_k (S v) = \mp I_k v$. Therefore, $S \in \sigma (\lambda, \ell)$, as desired. ■
Remark 4.3 If \((M,g)\) admits an integrable \((-1,1)\)-structure then \(g\) must be split. Indeed, any \(S \in \sigma (-1,1)\) is an anti-isometry of the nondegenerate symmetric form \(h = \text{Im} (b_1)\), whose signature is twice that of \(g\). Now, \(S\) sends any \textit{space-like subspace} of \((\mathbb{E}, h)\) to a \textit{time-like subspace}, and vice versa, and so \(h\) is split and the assertion follows.

Proof of Theorem 4.1 We consider first the case \(-\lambda \ell = k = -1\). By Proposition 4.2 we have that \(b_{-1}\) is \(\mathbb{C}\)-symmetric and nondegenerate. Now, by the Basis Theorem 4.2, there exist complex linear coordinates \((\phi_{-1})^{-1} : (\mathbb{E}, I_{-1}) \rightarrow \mathbb{C}^m\) such that \(B_{-1} := (\phi_{-1})^* b_{-1}\) has the form

\[
B_{-1} (Z, W) = Z^t W,
\]

where \(Z, W \in \mathbb{C}^m\) are column vectors and the superscript \(t\) denotes transpose.

Let \(\tilde{\Sigma}(\lambda, \ell)\) be the subset of \(\text{End}_\mathbb{R} (\mathbb{C}^m)\) corresponding to \(\sigma (\lambda, \ell)\) via the isomorphism \(\phi_{-1}\). By the second statement of Proposition 4.2 \(O(m, \mathbb{C})\) (the Lie group preserving \(B_{-1}\)) acts by conjugation on \(\tilde{\Sigma}(1, 1)\) and \(\tilde{\Sigma}(-1, -1)\).

Now, the symmetric form \(B_{-1}\) above coincides with the symmetric form \(B_+\) defined in the proof of Theorem 3.9 in [18] (except for the inessential fact that in that theorem the dimension of \(M\) is even). Moreover, the condition \(\mathbb{N}\) in Proposition 4.2 is the same as the condition \((5)\) in [18] Propostion 3.11. Hence \(\tilde{\Sigma}(1, 1; n)\) and \(\tilde{\Sigma}(-1, -1)\) correspond with the sets \(\Sigma(+, +; n)\) and \(\Sigma(-, +)\) given in the proof of [18] Theorem 3.9), respectively. Therefore, the assertions of the theorem in these cases hold.

Now we analyze the remaining cases \(-\lambda \ell = k = 1\). We have by Proposition 4.2 that \(b_1\) is \(\mathbb{L}\)-symmetric. We suppose as above that the pseudo Riemannian metric \(g\) on \(M\) has signature \((p, q)\) and that \(\mathcal{B} = \{u_1, \ldots, u_m\}\) is an orthonormal basis of \(T_p M\), with \(g(u_i, u_i) = 1\) for \(1 \leq i \leq p\) and \(g(u_j, u_j) = -1\) for \(j > p\). Since \(I_1 (u) = g^s (u)\) for any \(u \in T_p M\), an easy computation shows that the matrix of \(b_1\) with respect to \(\mathcal{B}\) (thought of as an \(\mathbb{L}\)-basis of \((\mathbb{E}, I_1)\)) is \(\varepsilon \text{ diag} (\text{id}_p, -\text{id}_q)\), where \(\text{id}_s\) is the \(s \times s\)-identity matrix. Therefore, there exist \(\mathbb{L}\)-linear coordinates \((\phi_1)^{-1} : (\mathbb{E}, I_1) \rightarrow \mathbb{L}^m\), such that \(B_1 := (\phi_1)^* b_1\) has the form

\[
B_1 ((Z_1, W_1), (Z_2, W_2)) = \varepsilon (Z_1^t Z_2 - W_1^t W_2),
\]

where \(Z_1, Z_2 \in \mathbb{L}^p\) and \(W_1, W_2 \in \mathbb{L}^q\). Let \(\mathbb{L}^{p,q}\) be \(\mathbb{L}^m\) endowed with the form \(B_1\).

Let \(\tilde{\Sigma}(\lambda, \ell)\) be the subset of \(\text{End}_\mathbb{R} (\mathbb{L}^m)\) corresponding to \(\sigma (\lambda, \ell)\) via the isomorphism \(\phi_1\).

Let \(e = (1 - \varepsilon) /2, \quad \overline{e} = (1 + \varepsilon) /2\), which are null Lorentz numbers forming an \(\mathbb{R}\)-basis of \(\mathbb{L}\). One has \(e^2 = \overline{e}^2 = \overline{\varepsilon}, e \overline{\varepsilon} = 0\) and \(\varepsilon e = -e, \varepsilon \overline{e} = \overline{e}\). Any element of \(\mathbb{L}^{p,q}\) can be written as \(xe + y\overline{e}\) with \(x, y \in \mathbb{R}^m\) and \(B_1\) has the form

\[
B_1 (x_1 e + y_1 \overline{e}, x_2 e + y_2 \overline{e}) = \varepsilon (e \langle x_1, x_2 \rangle_{p,q} + \overline{\varepsilon} \langle y_1, y_2 \rangle_{p,q}),
\]

where \(\langle \cdot, \cdot \rangle_{p,q}\) is the canonical nondegenerate symmetric bilinear form with signature \((p, q)\) on \(\mathbb{R}^m\).

Following Section 3 of [13], the group \(G\) of transformations preserving \(B_1\) is isomorphic to \(O(p, q) \times O(p, q)\); more precisely, by writing any element \(\hat{A}\) of \(G\) in the null basis, \(\hat{A} = Ae + B \overline{e}\), we have that \(A, B \in O(p, q)\) and

\[
\hat{A} (xe + y\overline{e}) = (Ax) e + (By) \overline{e}
\]

(10)
for all \( x, y \in \mathbb{R}^m \). Clearly \( G \) acts by conjugation on \( \tilde{\Sigma} (1, -1) \) and \( \tilde{\Sigma} (-1, 1) \).

**Case** \((1, -1)\): Let \( S \in \text{End} \mathbb{R} (\mathbb{L}^m) \) be the conjugation in \( \mathbb{L}^m \), that is, \( S (xe + ye) = ye + xe \), where \( x, y \in \mathbb{R}^m \). By Proposition 4.2 it is easy to check that \( S \in \tilde{\Sigma} (1, -1) \); indeed \( S^2 = 1 \).

\[
B_1 (S (x_1 e + y_1 e), S (x_2 e + y_2 e)) = B_1 (y_1 e + xe, y_2 e + xe) = \varepsilon (e \langle y_1, y_2 \rangle) + \langle xe, xe \rangle = -\varepsilon (e \langle x_1, x_2 \rangle) + \langle y_1, y_2 \rangle = -B_1 ((x_1 e + y_1 e), (x_2 e + y_2 e)).
\]

The isotropy subgroup at \( S \) of the action of \( G \equiv O(p, q) \times O(p, q) \) is isomorphic to the diagonal subgroup of \( O(p, q) \times O(p, q) \), which is isomorphic to \( O(p, q) \).

Now, we see that the action is transitive. Let \( T \in \tilde{\Sigma} (1, -1) \) and let \( D(\pm 1) \) be the \pm 1-eigenspaces of \( T \). Let us denote \( h = \text{Im} (B_1) \). One checks that \( h \) is a real symmetric bilinear form on \( \mathbb{L}^m \) of signature \((2p, 2q)\). We know from the proof of Proposition 4.2 that multiplication by \( \varepsilon \) sends \( D(1) \) to \( D(-1) \) (after the identification of \( \varepsilon \) with \( I_1 \) via \( \phi_i \)). Moreover, it is an isometry of \( \mathbb{L}^m, h \). Thus, if we call \( h^\pm = h_{D(\pm 1) \times D(\pm 1)} \), we obtain that \( \varepsilon : (D(1), h^+) \to (D(-1), h^-) \) is an isometry. Therefore \( h^+ \) and \( h^- \) have the same signature since \( D(1) \) and \( D(-1) \) are orthogonal with respect to \( h \) by (8). This yields that the signature of \( h^+ \) is \((p, q)\) since the signature of \( h \) is \((2p, 2q)\). Let \( \{\tilde{u}_1, \ldots, \tilde{u}_m\} \) be an orthonormal basis of \((D(1), h^+)\), where the first \( p \) vectors are space-like and the remaining vectors are time-like. We define the real linear transformation \( F \) by \( F (e_i) = \tilde{u}_i \), where \( \{e_i \mid i = 1, \ldots, m\} \) is the canonical basis of \( \mathbb{L}^m \). Then \( F \) extends \( \mathbb{L} \)-linearly to a map \( \tilde{F} \) preserving \( B_1 \) and satisfying \( T = \tilde{F} S \tilde{F}^{-1} \). Consequently, \( \tilde{\Sigma} (1, -1) \) can be identified with \( O(p, q) \times O(p, q) / O(p, q) \), as desired.

**Case** \((-1, 1)\): We know from Remark 4.3 that \( g \) is split. Let \( S \in \text{End} \mathbb{R} (\mathbb{L}^{2p}) \) be defined by \( S (xe + ye) = r (y) e - r (x) ye \), where \( x, y \in \mathbb{R}^{2p} \) and \( r (x_1, x_2) = (x_2, x_1) \), with \( x_i \in \mathbb{R}^p \). It is easy to check that \( S \in \tilde{\Sigma} (-1, 1) \) and that the isotropy subgroup at \( S \) of the action of \( O(p, p) \times O(p, p) \) consists of the maps \( A \) as in (10) with \( B = r Ar \). Hence, the isotropy subgroup is isomorphic to \( O(p, p) \).

It remains to show that the action is transitive. Let \( T \in \tilde{\Sigma} (-1, 1) \) and define \( R = \varepsilon T \). Note that \( R^2 = 1 \) and denote by \( D(\pm 1) \) the \pm 1-eigenspaces of \( R \). It is easy to check that \( h := \text{Re} (B_1) \) is a real symmetric bilinear form on \( \mathbb{L}^{2p} \) of signature \((2p, 2p)\). As before, we call \( h^\pm = h_{D(\pm 1) \times D(\pm 1)} \). In the same way as in the proof of the case \((1, -1)\), we have that \( \varepsilon : (D(1), h^+) \to (D(-1), h^-) \) is an isometry. Therefore, \( h^+ \) and \( h^- \) have the same signature and since \( D(1) \) and \( D(-1) \) are orthogonal with respect to \( h \) by (8), we have that the signature of \( h^+ \) is \((p, p)\). Let \( F \) be the real linear transformation sending an orthonormal basis of \((D(1), h^+)\) to an orthonormal basis of the 1-eigenspace of \( \varepsilon S \) (with the inner product induced from \( h \)). Then \( F \) extends \( \mathbb{L} \)-linearly to a map \( \tilde{F} \) preserving \( B_1 \) and satisfying \( R = \tilde{F} (\varepsilon S) \tilde{F}^{-1} \). It follows that \( T = \tilde{F} S \tilde{F}^{-1} \), and so \( T \) is conjugate to \( S \in O(p, p) \times O(p, p) \). □

### 5 Examples

We present two families of examples of left invariant integrable \((\lambda, \ell)\)-structures on Lie groups. In this case, the usually hardest computation, namely the verification of integrability, is simplified by the following fact (see [3, Section 3]).
Let $G$ be a Lie group with Lie algebra $\mathfrak{g}$. The Courant bracket of left invariant sections of $TG = G \times \mathfrak{g} \times \mathfrak{g}^*$ coincides, via the obvious identification, with the Lie bracket of the corresponding elements of the cotangent Lie algebra $T^*\mathfrak{g} = \mathfrak{g} \ltimes \mathfrak{ad}^* \mathfrak{g}^*$, that is, the direct sum of $\mathfrak{g} \oplus \mathfrak{g}^*$ endowed with the Lie bracket

$$[(x, \alpha), (y, \beta)] = ([x, y], -\beta \circ \text{ad}_x + \alpha \circ \text{ad}_y)$$

for $x, y \in \mathfrak{g}$ and $\alpha, \beta \in \mathfrak{g}^*$. So, essentially, a left invariant generalized (para)complex structure on a Lie group $G$ is the same as a left invariant (para)complex structure on the Lie group $T^*G$, which is skew-symmetric with respect to the bi-invariant canonical split metric on $T^*G$ (the proof of the assertion for the paracomplex case is similar to the proof of the complex case given in [3]). In this way, our examples 5.1 and 5.2 below can be set in the context of the articles [3] and [1], respectively.

5.1 Integrable $(-1, -1)$-structures on nilmanifolds

Generalized complex geometry was strengthened by the existence of manifolds admitting no known complex or symplectic structure but which do admit generalized complex structures. We have an analogous situation in our context of integrable $(\lambda, \ell)$-structures on a pseudo Riemannian manifold, in the invariant setting. It is known, for instance, that all 6-dimensional nilmanifolds admit generalized complex structures [6], but some of them admit neither complex nor symplectic left invariant structures [17, Theorem 5.1]. Nevertheless,

**Theorem 5.1** Any of the five 6-dimensional nilmanifolds admitting neither a left invariant complex nor a left invariant symplectic structure admits a left invariant pseudo Riemannian metric $g$ and a compatible integrable $(-1, -1)$-structure.

**Proof** By [17, Theorem 5.1], the five 6-dimensional nilpotent Lie algebras referred to in the statement of the theorem are (with the notation of that paper)

$$\mathfrak{g}_1 = (0, 0, 12, 13, 14 + 23, 34 + 52), \quad \mathfrak{g}_2 = (0, 0, 12, 13, 14 + 34 + 52),$$
$$\mathfrak{g}_3 = (0, 0, 12, 13, 14 + 35), \quad \mathfrak{g}_4 = (0, 0, 12, 23, 14 + 35),$$
$$\mathfrak{g}_5 = (0, 0, 12, 15 + 34).$$

Let $G_i$ denote the simply connected Lie group with Lie algebra $\mathfrak{g}_i$. Now we endow each $\mathfrak{g}_i$ with a pseudo Riemannian metric $g_i$. For $\mathfrak{g}_1$, the Gram matrix of $g_1$ with respect to the ordered basis

$$\{e_4, -4e_1 + e_4, -3e_1 - e_2 + e_3, -e_1 + e_2 + e_3, e_6, 2e_5 + e_6\}$$

is $C_1 = \text{diag} (4, -4, 2, -2, -2, 2)$; in particular, the signature of $g_1$ is $(3, 3)$. For the remaining cases we give the Gram matrix $C_i$ of $g_i$ with respect to the basis $\{e_1, \ldots, e_6\}$:

$$C_2 = \text{diag} (-2, 1, 1, 1, 1/2), \quad C_3 = \text{diag} (-1, 1, 1, 1, 1),$$
$$C_4 = \text{diag} (-2, 1, 2, 1, 1, 1), \quad C_5 = \text{diag} (-1, 1, -1, 1, 1, 1).$$

Finally, we give compatible integrable $(-1, -1)$-structures $S_i$ on $(G_i, g_i)$ in classical terms, as in [11], that is, we make explicit the $6 \times 6$-matrices $A^i$ and $B^i$ in each case with respect to the basis $\{e_1, \ldots, e_6\}$ (we write down only their nonzero components).
One can check that $S_i$ satisfies (2) for $\lambda = -1$ and (3) for $\kappa = -1$. It remains to check that $S_i$ is integrable. According to the fact above the statement of the theorem, we give the cotangent algebra $T^*g_i$ by specifying the Lie bracket on the basis $\{e_1, \ldots, e_6, e_1^*, \ldots, e_6^*\}$, where $e_i^* (e_j) = \delta_{ij}$. Since $g_i$ is a subalgebra of $T^*g_i$, and $g_i^*$ is an abelian subalgebra of $T^*g_i$, it suffices to compute $[e_i, e_j^*]$ for $1 \leq i, j \leq 6$. We list them following the notation above (for instance, $5^*1 + 6^*3$ in the forth place means that $[e_5^*, e_1] = [e_6^*, e_3] = e_4^*$):

For $g_1$: $(23^* + 34^* + 45^*, 3^*1 + 35^* + 6^*5, 4^*1 + 5^*2 + 46^*5, 5^*1 + 6^*3, 26^*, 0)$;
For $g_2$: $(23^* + 34^* + 45^*, 3^*1 + 6^*5, 4^*1 + 46^*, 5^*1 + 6^*3, 26^*, 0)$;
For $g_3$: $(24^* + 35^* + 46^*, 4^*1, 5^*1 + 56^*, 6^*1, 6^*3, 0)$;
For $g_4$: $(24^* + 46^*, 4^*1 + 35^*, 5^*2 + 56^*, 6^*1, 6^*3, 0)$;
For $g_5$: $(25^* + 56^*, 5^*1, 46^*, 6^*3, 6^*1, 0)$.

Using this, one computes that the Nijenhuis tensor of $S_i$ vanishes. Hence $S_i$ is integrable.

Notice that in general $B^j$ does not have maximal rank. This asserts that, in a certain sense, $S_i$ is far away from the extremal cases as in Example 3.4.

### 5.2 A curve of integrable $(1, -1)$-structures on the Riemannian manifold of ellipses

Although the theory of integrable $(\lambda, \ell)$-structures applies mostly to the pseudo Riemannian case (and even more to neutral signature) we have the following example in the Riemannian setting.

Given $a \in \mathbb{R}^2$ and a positive definite $2 \times 2$-matrix $A$ with $\det A = 1$, let

$$E (A, a) = \left\{ z \in \mathbb{R}^2 \mid (z - a)^t A^{-1} (z - a) = 1 \right\},$$

which is an ellipse enclosing a region of area $\pi$ (centered at the point $a$, with axes not necessarily parallel to the coordinate axes). Any such ellipse has this form and we call $E$ the space consisting of all of them.

The group $H = SL_2 (\mathbb{R}) \times \mathbb{R}^2$ of all area preserving affine transformations of the plane acts canonically and transitively on $E$, with isotropy subgroup $K = SO_2 \times \{0\}$ at $E (I, 0)$, the circle of radius 1 centered at the origin (in fact, $(A^{1/2}, a)$ sends $E (I, 0)$ to $E (A, a)$). Thus, we can identify $E = H/K$ and so $E$ is a four dimensional manifold. Consider on $H$ the left invariant Riemannian metric $g$ given at the identity by

$$g ((X, x), (Y, y)) = \text{tr} \ (X^t Y) + x^t y.$$
There is an $H$-invariant Riemannian metric $g$ on $\mathcal{E}$ such that the canonical projection $H \to \mathcal{E}$ is a Riemannian submersion. This metric $g$ on $\mathcal{E}$ turns out to be isometric to an irreducible left invariant Riemannian metric on a solvable Lie group $G$ whose metric Lie algebra has an orthonormal basis $\mathcal{B} = \{e_1, e_2, e_3, e_4\}$ such that

\[ [e_1, e_2] = [e_1, e_4] = 0, [e_3, e_4] = 2e_4, [e_4, e_2] = 2e_1, [e_3, e_1] = e_1, [e_2, e_3] = e_2 \]

(see [2] Example 3, page 19). One can take $G = T_1 \ltimes \mathbb{R}^2$, where $T_1$ is the group of upper triangular $2 \times 2$-matrices with determinant 1,

\[ e_1 = (0, (1, 0)), \quad e_2 = (0, (0, 1)), \quad e_3 = \left( \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, 0 \right) \text{ and } e_4 = \left( \begin{pmatrix} 0 & 2 \\ 0 & 0 \end{pmatrix}, 0 \right). \]

(Notice that the orthogonal projection of \( \begin{pmatrix} 0 & 2 \\ 0 & 0 \end{pmatrix} \) onto $SO_2(\mathbb{R})$ is $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.)

We will consider three geometric structures on $G$ compatible with the Riemannian metric: The first one, a Riemannian product structure $r$ whose eigendistributions are $D(1) = \text{span}\{e_1, e_2\}$ and $D(-1) = \text{span}\{e_3, e_4\}$ (both are subalgebras and the restriction of $g$ to them is trivially nondegenerate).

Now, we recall from Example 3 and Lemma 1 in [2] the definition of two left invariant almost complex structures $J_+$ and $J_-$ on $G$ given by $J_\varepsilon(e_1) = e_2$, $J_\varepsilon(e_3) = \varepsilon e_4$ ($\varepsilon = \pm 1$). It turns out that $(G, g, J_\varepsilon)$ is a Kähler manifold for $\varepsilon = 1$ and an almost Kähler manifold for $\varepsilon = -1$, which is not Kähler (for the definition of $J_-$ in terms of $J_+$ one computes that $D(1)$ and $D(-1)$ are the eigenspaces of the Ricci tensor of $\mathcal{E}$, with eigenvalues 0 and $-6$, respectively). We comment that $(G, g, J_-)$ is isomorphic to the unique proper 3-symmetric space in four dimension (see [2] [10] [15]).

Calling $\omega_\varepsilon$ the symplectic form associated to $J_\varepsilon$ and $g$, according to our nomenclature, $\omega_\varepsilon$ is then an integrable $(0, -1)$-structure on $G$. Let $R, Q_\varepsilon$ ($\varepsilon = \pm 1$) be the integrable $(1, -1)$-structures on $(G, g)$ associated with $r$ and $\omega_\varepsilon$, as in Example 3.3.4 respectively. The following proposition presents a curve $\Phi_\varepsilon$ of integrable $(1, -1)$-structures on $G$ joining $r$ with $\omega_\varepsilon$.

**Proposition 5.2** For any $t \in \mathbb{R}$,

\[ \Phi_\varepsilon(t) = \cos t \cdot R + \sin t \cdot Q_\varepsilon \]

defines a left invariant integrable $(1, -1)$-structure on $(\mathcal{E}, g)$.

**Proof** Since $R$ and $Q_\varepsilon$ are integrable $(1, 1)$-structures on $(G, g)$, they satisfy (2) for $\lambda = 1$ and (3) for $\kappa = 1$. This implies easily that $Q_\varepsilon(t)$ satisfies those conditions as well ($R$ and $Q_\varepsilon$ anticommutate). It remains only to check that the eigenspaces $D_\varepsilon(\delta)$ ($\delta = \pm 1$) are Courant involutive, or equivalently, by the fact stated at the beginning of the section, that they are Lie subalgebras of $T^*g$. For this, we consider the basis $\mathcal{C}$ of the cotangent algebra given by the juxtaposition of $\mathcal{B}$ with its dual basis $\{e_1^*, e_2^*, e_3^*, e_4^*\}$. As in the first example in this section, we have to compute only $[e_i, e_j^*]$, for $1 \leq i, j \leq 4$. In this case, we obtain

\[ [e_1, e_1^*] = e_3^*, [e_2, e_1^*] = 2e_4^*, [e_2, e_2^*] = -e_3^*, [e_3, e_1^*] = -e_1^*, \]
\[ [e_3, e_2^*] = e_2^*, [e_3, e_4^*] = -2e_4^*, [e_4, e_1^*] = -2e_2^*, [e_4, e_3^*] = 2e_3^*. \]
The matrix of $R$ with respect to $C$ is diag $(1, 1, -1, -1, -1, 1, 1)$ and the matrix of $Q_\varepsilon$ with respect to the same basis is
\[
\begin{pmatrix}
0_4 & -B_\varepsilon \\
B_\varepsilon & 0_4
\end{pmatrix}
\]
where
\[
B_\varepsilon = \text{diag (} j, \varepsilon j \text{)} \quad \text{with} \quad j = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},
\]
and $0_4$ denotes the $4 \times 4$ zero matrix. We have that the eigenspace $D_\varepsilon (\delta)$ is spanned by the vectors:
\[
\begin{align*}
-(\sin t) e_1 + (\cos t - \delta)e_2^*, & \quad (\sin t) e_2 + (\cos t - \delta)e_1^*, \\
\varepsilon(\sin t) e_3 + (\cos t + \delta)e_4^*, & \quad -\varepsilon(\sin t) e_4 + (\cos t + \delta)e_3^*.
\end{align*}
\]
An easy computation shows that any of these subspaces is a subalgebra of the cotangent algebra $T^*g$, as desired.
