1. Introduction and statement of results

Let $k$ be an algebraically closed field of characteristic zero. Given an integer $d \geq 2$, consider the associated polynomial ring $S := k[t_1, \ldots, t_d]$. Let $G$ be a cyclic subgroup of $SL(d, k)$ generated by $\text{diag}(\zeta^{a_1}, \ldots, \zeta^{a_d})$, where $\zeta$ is a primitive $n^{th}$ root of unit and $a_1, \ldots, a_d$ are integers satisfying the following conditions: we have $0 < a_j < n$ and $\gcd(a_j, n) = 1$ for every $1 \leq j \leq d$; we have $a_1 + \cdots + a_d = n$. The group $G$ acts naturally on $S$ and the invariant ring $R := S^G$ is a Gorenstein isolated singularity of Krull dimension $d$. For example, when $d = 2$, the ring $R$ identifies with the Kleinian singularity $k[u, v, w]/(u^n + vw)$ of type $A_{n-1}$.

The affine $k$-scheme $X := \text{Spec}(R)$ is singular. Following Orlov [5,4], we can then consider the associated dg category of singularities $\mathcal{D}^{\text{sing}}_{\text{dg}}(X)$, also known as matrix factorizations or maximal Cohen–Macaulay modules. Roughly speaking, this dg category encodes all the crucial information concerning the isolated singularity of $X$.

Let us denote by $(Q, \rho)$ the quiver with relations defined by the following steps:

(s1) consider the quiver with vertices $\mathbb{Z}/n\mathbb{Z}$ and with arrows $x_j^i : i \to i + a_j$, where $i \in \mathbb{Z}/n\mathbb{Z}$ and $1 \leq j \leq d$. The relations $\rho$ are given by $x_j^{i+a_j} = x_j^{i+j}$ for every $i \in \mathbb{Z}/n\mathbb{Z}$ and $1 \leq j, j' \leq d$;

(s2) remove from (s1) all arrows $x_j^i : i \to i'$ with $i > i'$;

(s3) remove from (s2) the vertex 0.

Consider the matrix $(n - 1) \times (n - 1)$ matrix $C$ such that $C_{ij}$ equals the number of arrows in $Q$ from $j$ to $i$ (counted modulo the relations). Let us write $M$ for the matrix $(-1)^{i-j}c(i^{-1})^T - \text{Id}$ and $M : \oplus_{r=1}^{n-1} \mathbb{Z}/l^r \to \oplus_{r=1}^{n-1} \mathbb{Z}/l^r$ for the associated (matrix) homomorphism, where $l^r$ is a (fixed) prime power.

**Theorem 1.1.** We have the following computation:

$$K_i(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) \simeq \begin{cases} \text{cokernel of } M & \text{if } i \geq 0 \text{ even,} \\ \text{kernel of } M & \text{if } i \geq 0 \text{ odd,} \\ 0 & \text{if } i < 0. \end{cases}$$

Thanks to **Theorem 1.1**, the computation of the (nonconnective) algebraic $K$-theory with coefficients of the cyclic quotient singularities reduces to the computation of (co)kernels of explicit matrix homomorphisms! To the best of the author’s knowledge, these computations are new in the literature. In the particular case of Kleinian singularities of type $A_n$ they were originally established in [8, §3].

**Corollary 1.2.**

(i) If there exists a prime power $l^r$ and an even (resp. odd) integer $j \geq 0$ such that $K_j(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) \neq 0$, then for every even (resp. odd) integer $i \geq 0$ at least one of the groups $K_i(D^{\text{sing}}_{\text{dg}}(X))$ and $K_{i-j}(D^{\text{sing}}_{\text{dg}}(X))$ is non-zero.

(ii) If there exists a prime power $l^r$ such that $K_i(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) = 0$ for every $i \geq 0$, then the groups $K_i(D^{\text{sing}}_{\text{dg}}(X)), i \geq 0$, are uniquely $l^r$-divisible.

**Proof.** Combine the following universal coefficients sequence (see [8, §5])

$$0 \longrightarrow K_i(D^{\text{sing}}_{\text{dg}}(X)) \otimes \mathbb{Z}/l^r \longrightarrow K_i(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) \longrightarrow \{l^r\text{-torsion in } K_{i-1}(D^{\text{sing}}_{\text{dg}}(X))\} \longrightarrow 0$$

with the computation of **Theorem 1.1**.

2. A low dimensional example

When $d = 3$, $n = 5$, $a_1 = 1$, and $a_2 = a_3 = 2$, the three steps (s1)-(s3) lead to the following quiver

```
1 \longrightarrow 2 \longrightarrow 3 \longrightarrow 4
```

with relations $xy = yx$, $yz = zy$, and $zx = xz$. Consequently, we obtain the following matrix

$$M = \begin{pmatrix} 0 & -1 & -3 & -3 \\ 1 & -1 & -4 & -6 \\ 3 & -2 & -10 & -13 \\ 3 & 0 & -11 & -19 \end{pmatrix}.$$ 

Since $\det(M) = 26$, we have $K_i(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) = 0$ whenever $l \neq 2, 13$. In the remaining two cases, a computation shows that $K_i(D^{\text{sing}}_{\text{dg}}(X); \mathbb{Z}/l^r) \simeq \mathbb{Z}/l$ for every $i \geq 0$. Thanks to **Corollary 1.2**, this implies that for every $i \geq 0$, at least one of the groups $K_i(D^{\text{sing}}_{\text{dg}}(X))$ and $K_{i-1}(D^{\text{sing}}_{\text{dg}}(X))$ is non-zero. Moreover, the groups $K_i(D^{\text{sing}}_{\text{dg}}(X)), i \geq 0$, are uniquely $l$-divisible for every prime $l \neq 2, 13$. 

3. A family of examples

When \( n = d \geq 3 \) and \( a_1 = \cdots = a_d = 1 \), the above three steps (s1)-(s3) lead to the following quiver

\[
\begin{array}{ccccccc}
1 & \cdots & 2 & \cdots & d - 3 & \cdots & d - 2 & \cdots & d - 1 \\
\vdots & & \vdots & & \vdots & & \vdots & & \vdots \\
x_1 & \cdots & x_1 & \cdots & x_1 & \cdots & x_1 & \cdots & x_1 \\
x_2 & \cdots & x_d & \cdots & x_2 & \cdots & x_d & \cdots & x_2 \\
\end{array}
\]

with relations \( x_j x_i = x_i x_j \). In the case where \( d \) is odd, we obtain the matrix

\[
M_{ij} = \begin{cases} 
- \sum_{r=0}^{i-1} \binom{d}{i-r} \binom{d}{j-i+r} & \text{if } i < j, \\
- \sum_{r=1}^{i-1} \binom{d}{i-r}^2 & \text{if } i = j, \\
- \sum_{r=1}^{j-1} \binom{d}{i-r} \binom{d}{j-i+r} + \binom{d}{i-1} & \text{if } i > j.
\end{cases}
\]

where \( \binom{d}{r} \) stands for the multicombination symbol.\(^2\) Similarly, in the case where \( d \) is even, we obtain

\[
M_{ij} = \begin{cases} 
\sum_{r=0}^{i-1} \binom{d}{i-r} \binom{d}{j-i+r} & \text{if } i < j, \\
-2 + \sum_{r=1}^{i-1} \binom{d}{i-r}^2 & \text{if } i = j, \\
\sum_{r=1}^{j-1} \binom{d}{i-r} \binom{d}{j-i+r} - \binom{d}{i-1} & \text{if } i > j.
\end{cases}
\]

Whenever \( d \) is a prime number, all the multicombinations

\[
\binom{d}{r} = \binom{d+r-1}{r} = \frac{(d+r-1) \cdots (d)}{r! (d-1)!}, \quad 0 \leq r \leq d - 2
\]

are multiples of \( d \). This implies that the homomorphism \( M: \bigoplus_{i=1}^{d-1} \mathbb{Z}/d \to \bigoplus_{i=1}^{d-1} \mathbb{Z}/d \) is zero, and consequently that \( \mathbf{K}_i(D^\text{sing}_{dg}(X); \mathbb{Z}/d) \simeq \bigoplus_{i=1}^{d-1} \mathbb{Z}/d \) for every \( i \geq 1 \). Thanks to Corollary 1.2(i), we hence conclude that for every \( i \geq 0 \) at least one of the groups \( \mathbf{K}_i(D^\text{sing}_{dg}(X)) \) and \( \mathbf{K}_{i-1}(D^\text{sing}_{dg}(X)) \) is non-zero.

4. Proof of Theorem 1.1

Let \( A \) be a finite dimensional \( k \)-algebra of finite global dimension. We write \( D^b(A) \) for the bounded derived category of (right) \( A \)-modules and \( D^b_{dg}(A) \) for the canonical \( dg \) enhancement of \( D^b(A) \). Consider the \( dg \) functors \( \tau^-1 \Sigma^d: D^b_{dg}(A) \to D^b_{dg}(A), \ d \geq 0, \) where \( \tau \) stands for the Auslander–Reiten translation. Following Keller [3, §7.2], we can consider the associated \( dg \) orbit category \( C^{(d)}_A := D^b_{dg}(A)/\langle \tau^-1 \Sigma^d \rangle \). Similarly to [8, Thm. 2.5] (consult [7, §2]), we have a distinguished triangle of spectra

\[
\bigoplus_{r=1}^v \mathbf{K}(k; \mathbb{Z}/l^r) \xrightarrow{(-1)^d \Phi - \text{Id}} \bigoplus_{r=1}^v \mathbf{K}(k; \mathbb{Z}/l^r) \xrightarrow{\Sigma} \bigoplus_{r=1}^v \mathbf{K}(c^{(d)}_A; \mathbb{Z}/l^r) 
\]

where \( v \) stands for the number of simple (right) \( A \)-modules and \( \Phi_A \) for the inverse of the Coxeter matrix of \( A \). Consider the following (matrix) homomorphism

\[
(-1)^d \Phi_A - \text{Id}: \bigoplus_{r=1}^v \mathbb{Z}/l^r \to \bigoplus_{r=1}^v \mathbb{Z}/l^r.
\]

As proved by Suslin in [6, Cor. 3.13], we have \( \mathbf{K}_i(k; \mathbb{Z}/l^r) \simeq \mathbb{Z}/l^r \) when \( i > 0 \) is even and \( \mathbf{K}_i(k; \mathbb{Z}/l^r) = 0 \) otherwise. Consequently, making use of the long exact sequence of algebraic \( K \)-theory groups with coefficients associated with the above distinguished triangle of spectra, we obtain the following computations:

\[
\mathbf{K}_i(c^{(d)}_A; \mathbb{Z}/l^r) \simeq \begin{cases} 
\text{cokernel of (1)} & \text{if } i \geq 0 \text{ even}, \\
\text{kernel of (1)} & \text{if } i \geq 0 \text{ odd,} \\
0 & \text{if } i < 0.
\end{cases}
\]

---

\(^2\) Also usually known as the multisubset symbol.
Consider also the dg functors $S^{-1}\Sigma^d: \mathcal{D}^b_{dg}(A) \to \mathcal{D}^b_{dg}(A)$, $d \geq 0$, where $S$ stands for the Serre dg functor. The associated dg orbit category $C_d(A) := \mathcal{D}^b_{dg}(A)/(S^{-1}\Sigma^d)^{dc}$ is usually called the generalized $d$-cluster dg category of $A$; see [1, §1.3] and the references therein. Since $S^{-1}\Sigma = \tau^{-1}$, we have $C_d(A) \simeq C_A^{(d-1)}$.

Now, let us take for $A$ the $k$-algebra $kQ/(\rho)$ associated with the quiver with relations $(Q, \rho)$. As proved independently by Amiot–Iyama–Reiten [1, §5] and Thanhoffer de Völcsey–Van den Bergh [2], we have $\mathcal{D}^{\text{sing}}_{dg}(X) \simeq C_{d-1}(A)$. Consequently, it remains then only to show that the homomorphism (1), with $d$ replaced by $d - 2$, agrees with the homomorphism $M$ associated with the matrix $M := (-1)^{d-1}C(C^{-1})^T - \text{Id}$. On the one hand, the number of simple (right) $A$-modules agrees with the number of vertices of the quiver $Q$. This implies that $v = n - 1$. On the other hand, the inverse of the Coxeter matrix of $A$ can be expressed as $-C(C^{-1})^T$, where $C_{ij}$ equals the number of arrows in $Q$ from $j$ to $i$ (counted modulo the relations). This implies that $(-1)^{d-2}\Phi_A - \text{Id} = (-1)^{d-1}C(C^{-1})^T - \text{Id} = M$, and hence concludes the proof.

Acknowledgement

The author is grateful to Michel Van den Bergh for useful discussions.
