Convergence and superconvergence analyses of HDG methods for time fractional diffusion problems

Kassem Mustapha\textsuperscript{1} · Maher Nour\textsuperscript{1} · Bernardo Cockburn\textsuperscript{2}

Abstract We study the hybridizable discontinuous Galerkin (HDG) method for the spatial discretization of time fractional diffusion models with Caputo derivative of order $0 < \alpha < 1$. For each time $t \in [0, T]$, when the HDG approximations are taken to be piecewise polynomials of degree $k \geq 0$ on the spatial domain $\Omega$, the approximations to the exact solution $u$ in the $L^\infty(0, T; L^2(\Omega))$-norm and to $\nabla u$ in the $L^\infty(0, T; L^2(\Omega))$-norm are proven to converge with the rate $h^{k+1}$ provided that $u$ is sufficiently regular, where $h$ is the maximum diameter of the elements of the mesh. Moreover, for $k \geq 1$, we obtain a superconvergence result which allows us to compute, in an elementwise manner, a new approximation for $u$ converging with a rate $h^{k+2}$ (ignoring the logarithmic factor), for quasi-uniform spatial meshes. Numerical experiments validating the theoretical results are displayed.

1 Introduction

In this paper, we study the method resulting from using exact integration in time and a hybridizable discontinuous Galerkin (HDG) method for the spatial discretization of the following time fractional diffusion model problem:

\[ c D^{1-\alpha} u(x, t) - \Delta u(x, t) = f(x, t) \quad \text{for } (x, t) \in \Omega \times (0, T], \tag{1a} \]
\[ u(x, t) = g(x) \quad \text{for } (x, t) \in \partial \Omega \times (0, T], \tag{1b} \]

with \( u(x, 0) = u_0(x) \) for \( x \in \Omega \), where \( \Omega \) is a convex polyhedral domain of \( \mathbb{R}^d (d = 1, 2, 3) \) with boundary \( \partial \Omega \), \( f \), \( g \) and \( u_0 \) are given functions assumed to be sufficiently regular such that the solution \( u \) of Eq. 1 is in the space \( W^{1, 1}(0, T; H^2(\Omega)) \), (further regularity assumptions will be imposed later), and \( T > 0 \) is a fixed but arbitrary value. Here, \( c D^{1-\alpha} \) denotes time fractional Caputo derivative of order \( \alpha \) defined by

\[ c D^{1-\alpha} v(t) := I^\alpha v'(t) := \int_0^t \omega_{\alpha}(t - s)v'(s) \, ds \quad \text{with } 0 < \alpha < 1, \tag{2} \]

where \( v' \) denotes the time derivative of the function \( v \) and \( I^\alpha \) is the Riemann–Liouville (time) fractional integral operator; with \( \omega_{\alpha}(t) := \frac{t^{\alpha-1}}{\Gamma(\alpha)} \) and \( \Gamma \) being the gamma function.

In this work, we investigate a high-order accurate numerical method for the space discretization for problem (1). Using exact integration in time, we propose to deal with the accuracy issue by developing a high-order HDG method that allows for locally varying spatial meshes and approximation orders which are beneficial to handle problems with low regularity. The HDG methods were introduced in [4] in the framework of steady-state diffusion which share with the classical (hybridized version of the) mixed finite element methods their remarkable convergence and superconvergence properties, [7], as well as the way in which they can be efficiently implemented, [13]. They provide approximations that are more accurate than the ones given by any other DG method for second-order elliptic problems [25]. In [6], a similar method was studied for the fractional subdiffusion problem:

\[ u'(x, t) - D^{1-\alpha} \Delta u(x, t) = f(x, t) \quad \text{for } (x, t) \in \Omega \times (0, T], \tag{3} \]

where \( D^{1-\alpha} \) is the Riemann–Liouville fractional time derivative operator,

\[ D^{1-\alpha} v(t) := (I^\alpha v(t))' = \frac{\partial}{\partial t} \int_0^t \omega_{\alpha}(t - s)v(s) \, ds. \tag{4} \]

(For other numerical methods of Eq. 3, see [2, 8, 9, 17–19, 22, 23, 29] and related references therein.) When \( f \equiv 0 \) (that is, homogeneous case), the two representations (1a) and (3) are different ways of writing the same equation, as they are equivalent under reasonable assumptions on the initial data. However, the numerical methods
obtained for each representation are formally different. In [6], the authors extended the approach of the error analysis used in [1] for the heat equation by using several important properties of $\mathcal{D}^{1-\alpha}$. Indeed, a duality argument was applied (where delicate regularity estimates were required) to prove the superconvergence properties of the method.

We start our work by introducing the spatial semi-discrete HDG method for the model problem (1) in the next section. In order to actually implement the HDG scheme, we discretize in time using a generalized Crank-Nicolson scheme [20]. The existence and uniqueness of the resulting fully discrete scheme will be shown. In Section 3, we prove the main optimal convergence results of the HDG method. Indeed, for each time $t \in [0, T]$, we prove that the error of the HDG approximation to the solution $u$ of problem (1) in the $L^\infty(0, T; L_2(\Omega))$-norm and to the flux $q := -\nabla u$ in the $L^\infty(0, T; L_2(\Omega))$-norm converge with order $h^{k+1}$ where $k$ is the polynomial degree and $h$ is the maximum diameter of the elements of the spatial mesh; see Theorem 2. Some important properties of the fractional integral operator $I^\alpha$ are used in our a priori error analysis. In Section 4, for quasi-uniform meshes and whenever $k \geq 1$, by a simple elementwise postprocessing with a computation cost that is negligible in comparison with that of obtaining the HDG approximate solution, we obtain a better approximation to $u$ converging in the $L^\infty(0, T; L_2(\Omega))$-norm with a rate of order $\sqrt{\log(T/h^2/(\alpha+1))}h^{k+2}$; see Theorem 3. Here, we partially rely on the superconvergence analysis of the postprocessed HDG scheme in [6, Section 5]. In Section 5, we present some numerical tests which indicate the validity of our theoretical optimal convergence rates of the HDG scheme as well as the superconvergence rates of the postprocessed HDG scheme.

Here is a brief history of the numerical methods for problem (1) in the existing literature. For the one dimensional case, a box-type scheme based on combining order reduction approach and an $L_1$-discretization was considered in [32]. An explicit finite difference (FD) method was studied in [26]. For an implicit FD scheme in time and Legendre spectral methods, we refer the reader to [15]. An extension of this work was considered in [14], where a time-space spectral method has been proposed and analyzed. An implicit Crank–Nicolson had been considered in [27] where the stability of the proposed scheme was proven. Two finite difference/element approaches were developed in [30]. Therein, the time direction was approximated by the fractional linear multistep method and the space direction was approximated by the standard finite element method (FEM). A compact difference scheme (fourth order in space) was proposed in [33] for solving problem (1) but with a variable diffusion parameter. The unconditional stability and the global convergence of the scheme were shown. In [28], a high-order local DG (LDG) method for space discretization was studied. Optimal convergence rates was proved.

For the two- (or three-) dimensional cases, a standard second-order central difference approximation was used in space, and, for the time stepping, two alternating direction implicit (ADI) schemes ($L_1$-approximation and backward Euler method) were investigated in [31]. A fractional ADI scheme for problem (1a) in 3D was proposed in [3]. Unique solvability, unconditional stability and convergence in $H^1$-norm were shown. A compact fourth order FD method (in space) with operator-splitting techniques was considered in [10]. The Caputo derivative was evaluated by the $L_1$
approximation, and the second order spatial derivatives were approximated by the fourth-order, compact (implicit) FDs. In [12], the authors developed two simple fully discrete schemes based on piecewise linear Galerkin FEMs in space and implicit backward differences for the time discretizations. Finally, a high-order accurate (variable) time-stepping discontinuous Petrov-Galerkin that allows low regularity combined with standard finite elements in space was investigated recently in [20]. Stability and error analysis were rigourously studied.

2 The HDG method

This section is devoted to defining a scalar approximation \( u_h(t) \) to \( u(t) \), a vector approximation \( q_h(t) \) to the flux \( q(t) \), and a scalar approximation \( \hat{u}_h(t) \) to the trace of \( u(t) \) on element boundaries for each time \( t \in [0, T] \), using a spatial HDG method. We begin by discretizing the domain \( \Omega \) by a conforming triangulation (for simplicity) \( T_h \) made of simplexes \( K \); we denote by \( \partial T_h \) the set of all the boundaries \( \partial K \) of the elements \( K \) of \( T_h \). We denote by \( E_h \) the union of faces \( F \) of the simplexes \( K \) of the triangulation \( T_h \).

Next, we introduce the discontinuous finite element spaces:

\[
W_h = \{ w \in L^2(\Omega) : w|_K \in \mathcal{P}_k(K) \quad \forall K \in T_h \},
\]

(5a)

\[
V_h = \{ v \in [L^2(\Omega)]^d : v|_K \in [\mathcal{P}_k(K)]^d \quad \forall K \in T_h \},
\]

(5b)

\[
M_h = \{ \mu \in L^2(E_h) : \mu|_F \in \mathcal{P}_k(F) \quad \forall F \in E_h \},
\]

(5c)

where \( \mathcal{P}_k(K) \) is the space of polynomials of total degree at most \( k \) in the spatial variable.

To describe our scheme, we rewrite (1a) as a first order system as follows: \( q + \nabla u = 0 \) and \( \partial_t^{1-\alpha} u + \nabla \cdot q = f \). So, \( q \) and \( u \) satisfy: for \( t \in (0, T] \),

\[
(q, \phi) - (u, \nabla \cdot \phi) + \langle u, \phi \cdot n \rangle = 0 \quad \forall \phi \in H(\text{div}, \Omega),
\]

(6a)

\[
(\partial_t^{1-\alpha} u, \chi) - (q, \nabla \chi) + \langle q \cdot n, \chi \rangle = (f, \chi) \quad \forall \chi \in H^1(\Omega).
\]

(6b)

where \( (v, w) := \sum_{K \in T_h} \langle v, w \rangle_K \) and \( \langle v, w \rangle := \sum_{K \in T_h} \langle v, w \rangle_{\partial K} \). Throughout the paper, for any domain \( D \) in \( \mathbb{R}^d \), by \( (u, v)_D = \int_D uv \, dx \) we denote the \( L^2 \)-inner product on \( D \). However, we use instead \( \langle u, v \rangle_D \) for the \( L_2 \)-inner product when \( D \) is a domain of \( \mathbb{R}^{d-1} \). We use \( \| \cdot \|_D \) to denote the \( L^2(D) \)-norm where we drop \( D \) when \( D = \Omega \). For vector functions \( v \) and \( w \), the notation is similarly defined with the integrand being the dot product \( v \cdot w \). For later use, the norm and semi-norm on any Sobolev space \( X \) are denoted by \( \| \cdot \|_X \) and \( | \cdot |_X \), respectively. We also denote \( \| \cdot \|_{X(0,T;Y(\Omega))} \) by \( \| \cdot \|_{X(Y)} \).

For each \( t > 0 \), the HDG method provides approximations \( u_h(t) \in W_h \), \( q_h(t) \in V_h \), and \( \hat{u}_h(t) \in M_h \) of \( u(t), q(t) \), and the trace of \( u(t) \), respectively. These are determined by requiring that

\[
(q_h, r) - (u_h, \nabla \cdot r) + \langle \hat{u}_h, r \cdot n \rangle = 0, \quad \forall r \in V_h,
\]

(7a)
\[(c D^{1-a} u_h, w) - (q_h, \nabla w) + (\hat{q}_h \cdot n, w) = (f, w), \quad \forall w \in W_h, \tag{7b} \]

\[(\tilde{u}_h, \mu)_{\partial \Omega} = (g, \mu)_{\partial \Omega}, \quad \forall \mu \in M_h, \tag{7c} \]

\[(\hat{q}_h \cdot n, \mu) - (\hat{q}_h \cdot n, \mu)_{\partial \Omega} = 0, \quad \forall \mu \in M_h, \tag{7d} \]

and take the numerical trace for the flux as

\[\hat{q}_h = q_h + \tau (u_h - \hat{u}_h) n \quad \text{on } \partial \Omega, \tag{7e} \]

for some nonnegative stabilization function \(\tau\) defined on \(\partial \Omega\); we assume that, for each element \(K \in \Omega\), \(\tau|_{\partial K}\) is constant on each of its faces. At \(t = 0\), \(u_h(0) \in W_h\) approximates the initial solution \(u_0\).

The first two equations are inspired by the weak form of the fractional differential equations satisfied by the exact solution, Eq. 6a. The form of the numerical trace given by Eq. 7d allows us to express \((u_h, q_h, \hat{q}_h)\) elementwise in terms of \(\hat{u}_h\) and \(f\) by using Eqs. 7a, 7b and 7e. Then, the numerical trace \(\hat{u}_h\) is determined by as the solution of the transmission condition (7d), which enforces the single-valuedness of the normal component of the numerical trace \(\hat{q}_h\), and the boundary condition (7c). Thus, the only globally-coupled degrees of freedom are those of \(\hat{u}_h\).

In our experiments, to implement our spatial semi-discrete HDG scheme (7), we use for simplicity a generalized Crank-Nicolson (CN) scheme for time discretization, see [20]. Formally, the CN scheme is second-order accurate provided that the continuous solution is sufficiently regular. To this end, we introduce a uniform partition of the time interval \([0, T]\) given by the points: \(t_i = i \delta\) for \(i = 0, \ldots, N\), with \(\delta = T/N\) being the time-step size. We take \(\delta\) to be sufficiently small so that the spatial discretizations errors are dominant.

The time-stepping CN combined with the HDG method provides approximations

\[u_h^j \in W_h, q_h^j \in V_h,\]

and \(\hat{u}_h^j \in M_h\) of \(u(t_j)\), \(q(t_j)\), and the trace of \(u(t_j)\), respectively, for \(j = 1, \ldots, N\). Starting from \(u_h^0 = u_h(0) \approx u_0\), and with appropriate choices of \(q_h^0\) and \(\hat{q}_h^0\), our fully discrete scheme is defined by:

\[
\begin{align*}
(J_{\alpha} \bar{u}_h(t_j), w) - (q_h^{j-\frac{1}{2}}, \nabla \cdot r) + (\hat{q}_h^{j-\frac{1}{2}} \cdot n, w) &= 0, \quad \forall w \in W_h, \\
(J_{\alpha} \bar{u}_h(t_j), w) - f^{j-\frac{1}{2}}(f(t_{j-1}) + f(t_j)), q_h^{j-\frac{1}{2}} &= (f^{j-\frac{1}{2}}, w), \quad \forall w \in W_h, \tag{8} \\
(q_h^j \cdot n, \mu_1) - (\hat{q}_h^{j-\frac{1}{2}} \cdot n, \mu_1)_{\partial \Omega} &= 0, \quad \forall \mu_1 \in M_h,
\end{align*}
\]

where \(f^{j-\frac{1}{2}} := \frac{1}{2}(f(t_{j-1}) + f(t_j))\), \(\hat{q}_h^{j-\frac{1}{2}} = q_h^{j-\frac{1}{2}} + \tau (u_h^{j-1} - \hat{u}_h^{j-1}) n \) on \(\partial \Omega\),

\[J_{\alpha} \bar{u}_h(t_j) = \int_{t_{j-1}}^{t_j} \int_0^t \omega_{\alpha}(t - s) \bar{u}_h(s) \, ds \, dt, \]

with \(\bar{u}_h(s) := \delta^{-1}(u_h^j - u_h^{j-1})\) for \(s \in (t_{i-1}, t_i)\), \(q_h^{j-\frac{1}{2}} := \frac{1}{2}(q_h^j + q_h^{j-1})\), and the functions \(u_h^{j-\frac{1}{2}}, \bar{u}_h^{j-\frac{1}{2}}, \) and \(q_h^{j-\frac{1}{2}}\) are similarly defined.

For each \(1 \leq j \leq N\), Eq. 8 amounts to a square linear system. Thus the existence of the CN HDG solution follows from its uniqueness. We prove the uniqueness by
induction hypothesis on \( j \). We let \( f_i := \frac{1}{2} (1 \leq i \leq j) \) and \( g \) be identically zero in Eq. 8, we assume that \((u^i_h, q^i_h, \tilde{q}^i_h) \equiv (0, 0, 0)\) for \( 1 \leq i \leq j - 1 \) and the task is to show that this holds true for \( i = j \). To do so, choose \( r = q^j_h, w = u^j_h, \mu = \tilde{q}^j \cdot n \) and \( \mu_1 = \tilde{u}^j_h \) in Eq. 8 and then simplify, yield

\[
\|q_h\|^2 - (u^j_h, \nabla \cdot q^j_h) + \langle \tilde{u}^j_h, q^j_h \cdot n \rangle = 0,
\]

\[
2J_{\alpha} u_h(t_j), u^j_h) - (q^j_h, \nabla u^j_h) + \langle \tilde{q}^j_h \cdot n, u^j_h \rangle = 0,
\]

\[
\langle \tilde{q}^j_h \cdot n, \tilde{u}^j_h \rangle = 0.
\]

Since \((u^j_h, \nabla \cdot q^j_h) = (\tilde{u}^j_h \cdot q^j_h \cdot n) - (q^j_h, \nabla u^j_h)\), adding the above equations give

\[
2(J_{\alpha} u_h(t_j), u^j_h) + \|q^j_h\|^2 + \|\tilde{q}^j_h - u^j_h \cdot (q^j_h - \tilde{q}^j_h) \cdot n\| = 0.
\]

Hence, by the induction hypothesis and the identity \((q^j_h - \tilde{q}^j_h) \cdot n = \tau (u^j_h - \tilde{u}^j_h)\) on \( \partial T_h \), we notes that

\[
2\int_0^{t_j} (I_{\alpha} u_h(t), u^j_h(t)) dt + \|q^j_h\|^2 + \|\tilde{q}^j_h - u^j_h \|^2_{\partial T_h} = 0,
\]

and therefore, the use of the coercivity property of \( I_{\alpha} \), Eq. 9, completes the proof.

3 Error estimates

In this section, we carry our a priori error analysis of the HDG method. First, we state the coercivity and continuity properties of \( I_{\alpha} \) [24, Lemma 3.1] that will be used throughout the paper: with \( c_{\alpha} := \cos(\frac{\alpha \pi}{2}) \),

\[
\int_0^T (I_{\alpha} v(t), v(t)) dt \geq c_{\alpha} \int_0^T \|I_{\alpha} v(t)\|^2 dt \quad \text{for} \quad v \in C(0, T; L_2(\Omega)),
\]

and for \( v, w \in C(0, T; L_2(\Omega)) \), we have

\[
2\int_0^T (v, I_{\alpha} w) dt \leq \int_0^T \left( \frac{1}{c_{\alpha}^2} (v, I_{\alpha} v) + (w, I_{\alpha} w) \right) dt.
\]

We also use the following integral inequality [6, Lemma 4]:

**Lemma 1** For any \( t \geq 0 \), suppose that \( E^2(t) \leq A(t) + 2 \int_0^t B(s) \ E(s) \ ds \), for some nonnegative functions \( A \) and \( B \). Then,

\[
E(T) \leq \max_{t \in (0, T)} A^{1/2}(t) + \int_0^T B(s) \ ds \quad \text{for any} \quad T > 0.
\]

Next, we define the projections which play the comparison function role in the error analysis. For each \( t \in (0, T] \), we assume that \( q(t) \in [H^1(T_h)]^d \) and
\( u(t) \in H^1(\mathcal{T}_h) \), where \( H^1(\mathcal{T}_h) = \prod_{K \in \mathcal{T}_h} H^1(K) \), the projections \( \Pi_v q(t) \in V_h \) and \( \Pi_w u(t) \in W_h \) are defined by: on each simplex \( K \in \mathcal{T}_h \) and for all faces \( F \) of \( K \),

\[
\begin{align*}
(\Pi_v q(t), v)_K &= (q(t), v)_K, \\
(\Pi_w u(t), w)_K &= (u(t), w)_K,
\end{align*}
\]

for all \( v \in [P_{k-1}(K)]^d \), \( w \in P_{k-1}(K) \) and \( \mu \in P_k(F) \). This projection introduced in [5] to study HDG methods for the steady-state diffusion problem and also used in the error analyses of HDG methods for classical diffusion [1] as well as for fractional subdiffusion [6] problems. As mentioned in [5], the projection \( \Pi_v \) depends not only on \( q \), but rather on both \( q \) and \( u \). Similarly for the projection \( \Pi_w \). Hence the notations \( \Pi_v \) and \( \Pi_w \) are somewhat misleading but convenient.

Its approximation properties are described in the following result.

**Theorem 1** ([5]) Suppose \( \tau|_{\partial K} \) is nonnegative and \( \tau_{K}^{\text{max}} := \max \tau|_{\partial K} > 0 \). Then the system (11) is uniquely solvable for \( \Pi_v q \) and \( \Pi_w u \). Furthermore, there is a constant \( C \) independent of \( K \) and \( \tau \) such that for each \( t \in (0, T] \),

\[
\begin{align*}
\|e_q(t)\|_K &\leq C h_{K}^{k+1} \left( |q(t)|_{H^{k+1}(K)} + \tau_{K}^{*} |u(t)|_{H^{k+1}(K)} \right), \\
\|e_u(t)\|_K &\leq C h_{K}^{k+1} \left( |u(t)|_{H^{k+1}(K)} + |\nabla \cdot q(t)|_{H^k(K)} / \tau_{K}^{\text{max}} \right),
\end{align*}
\]

where \( e_q := \Pi_v q - q \), \( e_u := \Pi_w u - u \), and \( h_K \) is the diameter of the spatial mesh element \( K \). Here \( \tau_{K}^{*} := \max \tau|_{\partial K \setminus F^*} \), where \( F^* \) is a face of \( K \) at which \( \tau|_{\partial K} \) is maximum.

Note that the approximation error of the projection is of order \( k + 1 \) provided that the stabilization function is such that both \( \tau_{K}^{*} \) and \( 1/\tau_{K}^{\text{max}} \) are uniformly bounded and the exact solution is sufficiently regular.

Thus, the main task now is to estimate the terms \( \varepsilon_u := \Pi_w u - u \) and \( \varepsilon_q := \Pi_v q - q_h \). For convenience, we further introduce the following notations: \( \varepsilon_{\tilde{u}} := P_M u - \tilde{u}_h \) and \( \varepsilon_{\tilde{q}} := P_M q - \tilde{q}_h \) where \( P_M \) denotes the \( L^2 \)-orthogonal projection onto \( M_h \), and \( P_M \) denotes the vector-valued projection each of whose components are equal to \( P_M \). For later use, for each \( t \in (0, T] \), Eq. 11c is equivalent to

\[
\langle \Pi_v q(t) \cdot n + \tau \Pi_w u(t) - P_M (q(t) \cdot n) - \tau P_M u(t), \mu \rangle_F \quad \forall \mu \in P_k(F).
\]

Since \( \Pi_v q(t) \cdot n + \tau \Pi_w u(t) - P_M (q(t) \cdot n) - \tau P_M u(t) \in P_k(F) \),

\[
\Pi_v q(t) \cdot n + \tau \Pi_w u(t) - P_M (q(t) \cdot n) - \tau P_M u(t) = 0 \quad \text{for each} \ t \in (0, T]. \quad (13)
\]

The projection of the errors satisfy the equations stated in the next lemma.
Lemma 2 For each $t > 0$, we have
\[
(e_q, r) - (\varepsilon_u, \nabla \cdot r) + (\varepsilon_\tilde{u}, r \cdot n) = (e_q, r), \quad \forall r \in V_h \tag{14a}
\]
\[
(I^a u', w) - (e_q, \nabla w) + (\varepsilon_\tilde{q} \cdot n, w) = (I^a e_u', w), \quad \forall w \in W_h \tag{14b}
\]
\[
(\varepsilon_\tilde{u}, \mu)_{\partial\Omega} = 0, \quad \forall \mu \in M_h \tag{14c}
\]
and we also have
\[
\varepsilon_\tilde{q} \cdot n := e_q \cdot n + \tau (\varepsilon_u - \varepsilon_\tilde{u}) \quad \text{on } \partial T_h. \tag{14e}
\]

Proof From (6), we recall that $q$ and $u$ satisfy the equations
\[
(q, r) - (u, \nabla \cdot r) + (u, r \cdot n) = 0, \quad \forall r \in V_h, \tag{14a}
\]
\[
(I^a u', w) - (q, \nabla w) + (q \cdot n, w) = (f, w), \quad \forall w \in W_h. \tag{14b}
\]
By the equalities $q = \Pi_v q - e_q$ and $u = \Pi_w u - e_u$, the fact that $P_M$ is the $L^2$—projection into $M_h$ and (11), we get
\[
(\Pi_v q, r) - (u, \nabla \cdot r) + (P_M u, r \cdot n) = (e_q, r), \quad \forall r \in V_h \tag{16}
\]
\[
(I^a (\Pi_w u)', w) - (q, \nabla w) + (\Pi_v q \cdot n + \tau (\Pi_w u - P_M u), w) = (f + I^a e_u', w), \quad \forall w \in W_h. \tag{17}
\]
Subtracting the Eqs. 7a and 7b from Eqs. 16 and 17, respectively, we obtain Eqs. 14a and 14b, respectively. The Eq. 14c follows directly from Eqs. 7c and 1b.

By the definition of $e_\tilde{q}$ and since $P_M$ is the $L^2$—projection into $M_h$, we have
\[
(\varepsilon_\tilde{q} \cdot n, \mu)_{\partial\Omega} = ((P_M q - \tilde{q}_h) \cdot n, \mu)_{\partial\Omega} - ((P_M q - \tilde{q}_h) \cdot n, \mu)_{\partial\Omega}
\]
\[
= ((q - \tilde{q}_h) \cdot n, \mu)_{\partial\Omega} - ((q - \tilde{q}_h) \cdot n, \mu)_{\partial\Omega}
\]
\[
= [(q \cdot n, \mu)_{\partial\Omega} - (q \cdot n, \mu)_{\partial\Omega}] - [(\tilde{q}_h \cdot n, \mu) - (\tilde{q}_h \cdot n, \mu)_{\partial\Omega}] = 0
\]
where in the last equality we used that $q$ is in $H(div, \Omega)$ and Eq. 7d. Thus, the identity (14d) holds. For the proof of Eq. 14e,
\[
\varepsilon_\tilde{q} \cdot n = P_M (q \cdot n) - (q_h \cdot n + \tau (u_h - \tilde{u}_h)) \quad \text{by (7e)},
\]
\[
= (\Pi_v q \cdot n + \tau (\Pi_w u - P_M u)) - (q_h \cdot n + \tau (u_h - \tilde{u}_h)) \quad \text{by (13)},
\]
\[
= e_q \cdot n + \tau (\varepsilon_u - \varepsilon_\tilde{u}). \quad \square
\]
Let $S_h := \|\sqrt{T}(e_u - e_u^h)\|_{\partial T_h}$. For $T > 0$,
\[
\int_0^T (I^\alpha e_u', e_u') \, dt + \|e_q(T)\|^2 + S_h^2(T) \leq \|e_q(0)\|^2 + S_h^2(0) + \frac{1}{\alpha} \int_0^T (I^\alpha e_u', e_u') \, dt + 2 \int_0^T (e_q', e_q) \, dt.
\]

**Proof** Since $(e_u, \nabla \cdot r) = -(\nabla e_u, r) + \langle e_u, r \cdot n \rangle$, Eq. 14a can be rewritten as:
\[
(e_q, r) + (\nabla e_u, r) + \langle e_u - e_u^h, r \cdot n \rangle = (e_q, r).
\]
A time differentiation of both sides yields,
\[
\left(\frac{d}{dt} e_q'\right, r) + (\nabla e_u', r) + \langle e_u^\prime - e_u', r \cdot n \rangle = (e_q, r).
\]
Setting $r = e_q$ and choosing $w = e_u'$ in Eq. 14b, we observe that
\[
(I^\alpha e_u', e_u') - (e_q, \nabla e_u) + \langle e_u^\prime \cdot n, e_u' \rangle = (I^\alpha e_u', e_u').
\]
Combining the above two equations and using $(e_q', e_q) = \frac{1}{2} \frac{d}{dt} \|e_q\|^2$, we obtain
\[
(I^\alpha e_u', e_u') + \frac{1}{2} \frac{d}{dt} \|e_q\|^2 + \psi_h = (I^\alpha e_u', e_u') + (e_q', e_q) + \psi_h,
\]
where
\[
\psi_h = \langle e_u^\prime - e_u', e_q \cdot n \rangle + \langle e_u^\prime \cdot n, e_u' \rangle.
\]
A time differentiation of Eq. 14c followed by choosing $\mu = e_q \cdot n$ and then using Eq. 14d yields $\langle e_q \cdot n, e_q' \rangle_{\partial\Omega} = \langle e_u^\prime \cdot n, e_u' \rangle = 0$. Thus, by Eq. 14e,
\[
\psi_h = \langle e_u^\prime - e_u', (e_q - e_q^\prime) \cdot n \rangle = \langle (e_u - e_u^h), (e_u^h - e_u) \rangle = \frac{1}{\alpha} \frac{d}{dt} S_h^2(t).
\]
Now, integrating Eq. 18 over the time interval $[0, T]$ and using Eq. 19, we get
\[
\int_0^T (I^\alpha e_u', e_u') \, dt + \frac{1}{2} \int_0^T \frac{d}{dt} \|e_q\|^2 + S_h^2 \, dt = \int_0^T (I^\alpha e_u', e_u') \, dt + \int_0^T (e_q', e_q) \, dt.
\]
Therefore,
\[
2 \int_0^T (I^\alpha e_u', e_u') \, dt + \|e_q(T)\|^2 + S_h^2(T) = \|e_q(0)\|^2 + S_h^2(0) + 2 \int_0^T (I^\alpha e_u', e_u') \, dt + 2 \int_0^T (e_q', e_q) \, dt.
\]
An application of the continuity property of the fractional derivative operator $I^\alpha$, Eq. 10, yields
\[
2 \int_0^T (I^\alpha e_u', e_u') \, dt \leq \frac{1}{\alpha} \int_0^T (I^\alpha e_u', e_u') \, dt + \int_0^T (I^\alpha e_u', e_u') \, dt.
\]
Finally, inserting this in Eq. 20 and simplifying completes the proof. \qed
Next, we show the main error bounds of the HDG method. For the remaining part of the paper, we choose \( u_h(0) = \Pi_h u_0 \) and so, \( \varepsilon_u(0) = 0 \).

**Theorem 2** Assume that \( u \in C^1(0, T; H^{k+1}(\Omega)) \) and \( q \in C^1(0, T; H^{k+1}(\Omega)) \). Assume also that \( \tau_K^* \) and \( 1/\tau_K^{\max} \) are bounded by \( C \). Then we have that
\[
\|(u - u_h)(T)\| + \|(q - q_h)(T)\| \leq C_1(1 + T) h^{k+1}.
\]
The constant \( C_1 \) only depends on \( C, \alpha, \|u\|_{C^1(H^{k+1})} \), and on \( \|q\|_{C^1(H^{k+1})} \).

**Proof** From the decompositions: \( u - u_h = \varepsilon_u - e_u \) and \( q - q_h = \varepsilon_q - e_q \), and the error projection in Theorem 1, we have
\[
\|(u - u_h)(T)\| + \|(q - q_h)(T)\| \leq C_1 h^{k+1} + \|\varepsilon_u(T)\| + \|\varepsilon_q(T)\|.
\]
The task now is to estimate \( \|\varepsilon_u(T)\| \) and \( \|\varepsilon_q(T)\| \). From Lemma 3, for \( t \geq 0 \), we have
\[
E(t) \leq A(t) + \int_0^t B(s) E(s) ds
\]
where
\[
A(t) := \|\varepsilon_q(0)\|^2 + S_h^2(0) + \frac{1}{c^2} \int_0^t (T^\alpha e_u', e_u') ds, \quad B(t) := \|e_q'(t)\|,
\]
\[
E(t) := \left( \|\varepsilon_q(t)\|^2 + \int_0^t (T^\alpha e_u', e_u') ds \right) \frac{1}{2}.
\]
Thus, an application of the integral inequality in Lemma 1, yields
\[
E(T) \leq \max_{t \in (0, T)} A_{t}^\frac{1}{2} + \int_0^T B(s) ds \quad \text{for any} \quad T > 0.
\]
Hence,
\[
\|\varepsilon_q(T)\|^2 + \int_0^T (T^\alpha e_u', e_u') ds \leq C \left( \|\varepsilon_q(0)\|^2 + S_h^2(0) + \int_0^T \left( \frac{1}{c^2} \|T^\alpha e_u'\| \|e_u'\| + T \|e_q'\|^2 \right) ds \right) . (21)
\]
However, since \( \varepsilon_u(t) = \int_0^t e_u'(s) ds = T^{\frac{1}{2}} (T^{\alpha} e_u'(t)) \) because \( \varepsilon_u(0) \), by the Cauchy-Schwarz inequality and the coercivity property of the operator \( T^{\alpha} \), Eq. 9,
\[
\|\varepsilon_u(t)\|^2 \leq \left( \int_0^t \omega_1^{\frac{1}{2}}(t - s) \|T^\alpha e_u'(s)\| ds \right)^2 \leq \int_0^t \omega_1^{\frac{1}{2}}(s) ds \int_0^t \|T^\alpha e_u'(s)\|^2 ds \leq \frac{t^{1 - \alpha}}{(1 - \alpha) \Gamma^2(1 - \frac{\alpha}{2})} \int_0^t \|T^\alpha e_u'(s)\|^2 ds \leq \frac{t^{1 - \alpha}}{(1 - \alpha) \Gamma^2(1 - \frac{\alpha}{2})} c_a \int_0^t (T^\alpha e_u', e_u') ds.
\]
Therefore, combining Eq. 21 with the above bound, and apply Theorem 1 for the time derivative error projections $\epsilon_u'$ and $\epsilon_q'$, we obtain

$$\|\epsilon_q(t)\|^2 + \|\epsilon_u(t)\|^2 \leq C_1^2(1 + T)^2\left(\|\epsilon_q(0)\|^2 + S_h^2(0) + h^{2k+2}\right).$$

To complete the proof, we need to bound $\|\epsilon_q(0)\|^2 + S_h^2(0)$.

Since $(\epsilon_u, \nabla \cdot r) = -(\nabla \epsilon_u, r) + \langle \epsilon_u, r, n \rangle$, setting $r = \epsilon_q$ in Eq. 14a and $w = \epsilon_u'$ in Eq. 14b yield

$$\|\epsilon_q\|^2 + (\nabla \epsilon_u, \epsilon_q) + \langle \epsilon_q - \epsilon_u, \epsilon_q \cdot n \rangle = (\epsilon_q, \epsilon_q),$$

$$(T^\alpha \epsilon_u', \epsilon_u) = (T^\alpha \epsilon_u', \epsilon_u) - (\epsilon_q, \nabla \epsilon_u) + \langle \epsilon_q \cdot n, \epsilon_u \rangle = (T^\alpha \epsilon_u', \epsilon_u).$$

Adding the above equations, and using $\langle \epsilon_q \cdot n, \epsilon_q \rangle = 0$ (this follows by choosing $\mu = \epsilon_q \cdot n$ in Eq. 14c and $\mu = \epsilon_q$ in Eq. 14d) and 14e, we obtain

$$(T^\alpha \epsilon_u', \epsilon_u) + \|\epsilon_q\|^2 + S_h^2 = (T^\alpha \epsilon_u', \epsilon_u) + (\epsilon_q, \epsilon_q).$$

Now, integrating over the time interval $[0, t]$, observing that

$$\int_0^t (T^\alpha \epsilon_u', \epsilon_u) \, ds = \int_0^t (D^{1-\alpha} \epsilon_u, \epsilon_u) \, ds \geq 0,$$

(in the first equality we used $\epsilon_u(0) = 0$ and the last inequality follows from the nonnegativity property of the Riemann–Liouville fractional derivative operator $D^{1-\alpha}$, see [16, Section 2]) and using the inequality $(\epsilon_q, \epsilon_q) \leq \frac{1}{2}\|\epsilon_q\|^2 + \frac{1}{2}\|\epsilon_q\|^2$, we get

$$\int_0^t [\frac{1}{2}\|\epsilon_q\|^2 + S_h^2] \, ds \leq \int_0^t \left(\|T^\alpha \epsilon_u'\| \|\epsilon_u\| + \frac{1}{2}\|\epsilon_q\|^2\right) \, ds.$$

Therefore, by the mean value theorem for integrals, there exist $t^*, \tilde{t} \in (0, t)$ such that

$$t\left(\frac{1}{2}\|\epsilon_q(t^*)\|^2 + S_h^2(t^*)\right) \leq \tilde{t}\left(\|\epsilon_u(\tilde{t})\| \max_{s \in (0, t)} \|T^\alpha \epsilon_u'(s)\| + \frac{1}{2}\max_{s \in (0, t)} \|\epsilon_q(s)\|^2\right).$$

Finally, dividing by $t$, taking the limit when $t$ goes to zero, and using again the fact that $\epsilon_u(0) = 0$, we observe that $\|\epsilon_q(0)\|^2 + S_h^2(0) \leq \|\epsilon_q(0)\|^2 \leq C_1 h^{2k+2}$ by the error estimate of $\epsilon_q$ given in Theorem 1. The proof is now complete. \qed

### 4 Superconvergence and post-processing

In this section, we seek a better approximation to $u$ by means of an element-by-element postprocessing. We begin by describing such approximation, then we show how to get our superconvergence result by a duality argument.

Following [1, 11], for each $t \in [0, T]$, we define the postprocessed HDG solution $u^*_h(t) \in P_{k+1}(K)$ to $u(t)$ for each simplex $K \in T_h$, as follows:

$$(u^*_h(t), 1)_K = (u_h(t), 1)_K \quad (22a)$$

$$(\nabla u^*_h(t), \nabla w)_K = -(q_h(t), \nabla w)_K \quad \forall w \in P_{k+1}(K). \quad (22b)$$

Since (22) amounts to a square linear system (for each fixed $t \in (0, T]$), the existence of the postprocessed HDG solution follows from its uniqueness. To this end, we let
\
\begin{align*}
u_h(t) \text{ and } q_h(t) \text{ to be identically zero in (22). The task is to show that } u_h^*(t) = 0 \text{ for each } t \in (0, T]. \text{ We choose } w = u_h^*(t) \text{ in Eq. 22b and observe that } u_h^*(t) \text{ is equal to a constant } c_0 \text{ on } K. \text{ Hence, by Eq. 22a, it is easy to see that } c_0 = 0. \\
\text{For showing the superconvergence property of } u_h^*, \text{ splitting the postprocessed error as: } u - u_h^* = (u - P_{k+1}u) + P_0\zeta + (\zeta - P_0\zeta) \text{ where } \zeta = P_{k+1}u - u_h^* \text{ and } P_\ell \text{ (for } \ell \geq 0) \text{ be the } L^2(\Omega)\text{-projection into the space of functions which are polynomials of total degree } \leq \ell \text{ on each element } K \in T_h. \text{ Hence, by the triangle inequality and the error properties of the projection } P_\ell, \\
\|u - u_h^*\| \leq Ch^{k+2} \|u\|_{H^{k+2}(\Omega)} + ||P_0\zeta\|_K + Ch\|\nabla \zeta\|_K. \tag{23}
\end{align*}

By the definition of \(u_h^*, \) Eqs. 22a and 22b, and the definition of the projection operator \(P_w, \) Eq. 11b, we have
\[
\begin{align*}
\|P_0\zeta\|_K^2 &= (P_{k+1}u - u_h, P_0\zeta)_K = (P_{k+1}u - u, P_0\zeta)_K + (P_0\varepsilon_u, P_0\zeta)_K \\
\|\nabla \zeta\|_K^2 &= (\nabla P_{k+1}u + q_h, \nabla \zeta)_K = (\nabla (P_{k+1}u - u), \nabla \zeta)_K - (q - q_h, \nabla \zeta)_K.
\end{align*}
\]

We combine the above three equations and then we apply the Cauchy-Schwarz and simplify to observe that
\[
\|u - u_h^*(T)\|_K \leq Ch^{k+2} \|u(T)\|_{H^{k+2}(\Omega)} + ||P_0\varepsilon_u(T)\|_K + Ch \|(q - q_h)(T)\|_K. \tag{24}
\]

The main task now is to show that the term \(||P_0\varepsilon_u(T)\|\) is of order \(O(h^{k+2}).\) Then the postprocessed approximation \(u_h^*\) would converge faster than the original approximation \(u_h.\) Noting that \(||P_0\varepsilon_u(T)\| = \sup_{\Theta \in C^\infty(\Omega)} \frac{(P_0\varepsilon_u(T), \Theta)}{\|\Theta\|}.\) To estimate the expression \((P_0\varepsilon_u(T), \Theta),\) we use the traditional duality approach by using the solution of the dual problem
\[
\Phi + \nabla \Psi = 0 \text{ and } (I^{\alpha*}\Psi)' - \nabla \cdot \Phi = 0 \text{ on } \Omega \times (0, T), \tag{25}
\]
with \(\Psi = 0 \text{ on } \partial \Omega \times (0, T)\) and \(\Psi(T) = 0 \text{ on } \Omega,\) where \(I^{\alpha*}\) is the adjoint operator of \(I^\alpha\) defined by [23]:
\[
I^{\alpha*}\psi(t) = \int_t^T \omega_\alpha(s-t) \psi(s) \, ds.
\]

Integrating \((I^{\alpha*}\Psi)' - \nabla \cdot \Phi = 0\) over the time interval \((t, T),\) we obtain
\[
I^{\alpha*}\psi(t) + \int_t^T \nabla \cdot \Phi(s) \, ds = 0. \tag{26}
\]

We define now the adjoint \(D^{\alpha*}\) of the Riemann–Liouville fractional derivative operator \(D^\alpha\) (see (4) for the definition of \(D^\alpha\)) as follows [23]: for \(t \in (0, T),\)
\[
D^{\alpha*}v(t) = -\frac{\partial}{\partial t} \int_t^T \omega_{1-\alpha}(s-t) \, v(s) \, ds \text{ for any } v \in C^1(0, T).
\]

Since \(\int_t^T \omega_\alpha(s-t) \omega_{1-\alpha}(q-s) \, ds = 1,\) it is easy to see that \(I^{\alpha*}\) is the right-inverse of \(D^{\alpha*},\) that is, \(D^{\alpha*}(I^{\alpha*}\Psi)(t) = \Psi(t).\) Hence, using this after applying the operator \(D^{\alpha*}\) to both sides of Eq. 26, yields
\[
\Psi(t) + D^{\alpha*} \left( \int_t^T \nabla \cdot \Phi(q) \, dq \right) = 0. \tag{27}
\]
However, since
\[
D^{\alpha^*} \left( \int_t^T \nabla \cdot \Phi(s) \, ds \right) = -\frac{\partial}{\partial t} \int_t^T \omega_1 \nabla \cdot \Phi(q) \, dq \, ds
\]
\[
= -\frac{\partial}{\partial t} \int_t^T \omega_2 \nabla \cdot \Phi(q) \, dq \, ds
\]
differentiating both sides of Eq. 27 with respect to \( t \), yield \( \Psi' - \nabla \cdot D^{\alpha^*} \Phi = 0 \). Therefore, an alternative formulation of the dual problem (25) is given by:
\[
\Phi + \nabla \Psi = 0 \text{ on } \Omega \times (0, T), \tag{28a}
\]
\[
\Psi' - \nabla \cdot D^{\alpha^*} \Phi = 0 \text{ on } \Omega \times (0, T), \tag{28b}
\]
\[
\Psi = 0 \text{ on } \partial \Omega \times (0, T), \tag{28c}
\]
\[
\Psi(T) = \Theta \text{ on } \Omega. \tag{28d}
\]

In the next lemma, an expression for the quantity \( (P_0 \varepsilon_u(T), \Theta) \) in terms of the errors \( \varepsilon_u', \varepsilon_q \), the projection errors \( e_q \) and \( e_u' \), and the solution of the dual problem will be given. In it, \( I_h \) is any interpolation operator from \( L^2(\Omega) \) into \( W_h \cap H^1_0(\Omega) \), \( P_w \) is the \( L^2 \)-projection into \( W_h \) and \( \Pi^{\text{BDM}} \) is the well-known projection associated to the lowest-order Brezzi-Douglas-Marini (BDM) space.

**Lemma 4** Assume that \( k \geq 1 \). Then, for any \( T > 0 \),
\[
(P_0 \varepsilon_u(T), \Theta) = \int_0^T [(\varepsilon_q, D^{\alpha^*} (\nabla I_h \Psi) - \Pi^{\text{BDM}} \nabla \Psi) + (e_q, D^{\alpha^*} (\Pi^{\text{BDM}} \nabla - \nabla P_w \Psi)) + (\varepsilon_u', P_0 \Psi - I_h \Psi)] \, dt.
\]

**Proof** Since \( \Psi(T) = \Theta \) by Eq. 28d and \( \varepsilon_u(0) = 0 \), we have
\[
(P_0 \varepsilon_u(T), \Theta) = \int_0^T [(\varepsilon_u, P_0 \Psi) + (P_0 \varepsilon_u', \Psi')] \, dt
\]
by the definition of the \( L^2 \)-projection \( P_0 \) and by Eq. 28b.

By the commutativity property \( P_0 \nabla \cdot = \nabla \cdot \Pi^{\text{BDM}} \) and the first error equation (14a) with \( r := D^{\alpha^*} \Pi^{\text{BDM}} \Phi \) (since \( k \geq 1 \)), we get for each \( t \in (0, T] \),
\[
(\varepsilon_u, P_0 \nabla \cdot D^{\alpha^*} \Phi) = \left( \varepsilon_u, \nabla \cdot D^{\alpha^*} \Pi^{\text{BDM}} \Phi \right),
\]
\[
= \left( \varepsilon_q, D^{\alpha^*} \Pi^{\text{BDM}} \Phi \right) + \langle \varepsilon_u', D^{\alpha^*} \Pi^{\text{BDM}} \Phi \cdot n \rangle - \left( e_q, D^{\alpha^*} \Pi^{\text{BDM}} \Phi \right)
\]
\begin{align*}
&= \left( \varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi \right) - \left( \varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi \right) \\
&= \left( \varepsilon_q, D^{\alpha*} ( - \Pi^{BDM} \nabla h \psi + \nabla I_h \psi ) \right) - \left( \varepsilon_q, D^{\alpha*} ( \nabla I_h \psi ) \right) \\
&\quad - \left( \varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi \right).
\end{align*}

Noting that, in the second last equality we used
\[ \langle \varepsilon_h, D^{\alpha*} \Pi^{BDM} \Phi \cdot n \rangle = \langle \varepsilon_h, D^{\alpha*} \Pi^{BDM} \Phi \cdot n \rangle_{\partial \Omega} = 0 \]
which follows from Eq. 14d (because \( D^{\alpha*} \Pi^{BDM} \Phi \in H(\text{div}, \Omega) \)) and the fact that \( \varepsilon_h = 0 \) on \( \partial \Omega \) by Eq. 14c.

But, by the error (14b) with \( w := D^{\alpha*} ( I_h \psi ) \),
\[ (\varepsilon_q, D^{\alpha*} ( \nabla I_h \psi )) = (\partial_t ( e^u_h - e'_u ), D^{\alpha*} ( I_h \psi )) + (\varepsilon_h \cdot n, D^{\alpha*} ( I_h \psi )) . \]

Now, putting together all the above intermediate steps,
\begin{align*}
(P_0 \varepsilon_u (T), \Theta) &= \int_0^T \left[ (e'_u, P_0 \psi) + (\varepsilon_q, D^{\alpha*} ( \nabla I_h \psi - \Pi^{BDM} \nabla \psi ) ) \\
&\quad - (D^{\alpha} \partial_t ( e^u_h - e'_u ) , I_h \psi ) - (\varepsilon_h \cdot n, D^{\alpha*} ( I_h \psi )) \\
&\quad - (\varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi ) \right] dt.
\end{align*}

But, \( \langle \varepsilon_h \cdot n, D^{\alpha*} ( I_h \psi ) \rangle = \langle \varepsilon_h \cdot n, D^{\alpha*} ( I_h \psi ) \rangle_{\partial \Omega} = 0 \) by Eq. 14d and the identity \( I_h \psi = 0 \) on \( \partial \Omega \) by the boundary condition of the dual problem (28c). Using this and the identity \( D^{\alpha} ( \partial_t ( e^u_h - e'_u ) ) = (e_u - e_u)' \) in Eq. 29, we observe
\begin{align*}
(P_0 \varepsilon_u (T), \Theta) &= \int_0^T \left[ (\varepsilon_q, D^{\alpha*} ( \nabla I_h \psi - \Pi^{BDM} \nabla \psi ) ) \\
&\quad - (\varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi ) + (e'_u, P_0 \psi - I_h \psi ) + (e'_u, I_h \psi ) \right] dt.
\end{align*}

Therefore, the desired result now follows after noting that
\[ - \int_0^T (\varepsilon_q, D^{\alpha*} \Pi^{BDM} \Phi ) \ dt = \int_0^T (\varepsilon_q, D^{\alpha*} ( \Pi^{BDM} \nabla \psi - \nabla P_w \psi ) ) \ dt, \]
(by Eq. 28a, the fact that \( P_w \) is the \( L^2 \)-projection into \( W_h \), and the orthogonality property of the projection \( \Pi_v \), Eq. 11a) and that \( (e'_u, I_h \psi ) = (e'_u, I_h \psi - P_0 \psi ) \) (by the fact that \( P_0 \psi \) is constant on each element \( K \in \mathcal{T}_h \), and the orthogonality property of the projection \( \Pi_w \), Eq. 11b). The proof is completed now. \( \square \)

In the next theorem we state the superconvergence estimate of the postprocessed HDG approximation. For the proof, we follow the derivation in [6, Section 5] step-by-step and use Lemma 4 instead of [6, Lemma 7], and we also use the achieved HDG error estimates in Theorem 2.

**Theorem 3** Assume that \( u \in C^1 (0, T; H^{k+2}(\Omega)) \) and \( q \in C^1 (0, T; H^{k+1}(\Omega)) \). Assume also that \( \tau_k^* \) and \( 1/\tau_k^{\max} \) are bounded by \( C \). Then, we have
\[ \|(u - u_h^*)(T)\| \leq C \max \left\{ 1, \sqrt{\log (Th^{-2/(\alpha+1)})} \right\} h^{k+2} \text{ for } k \geq 1, \]
where the constant $C_2$, only depends on $C$, $\alpha$, $T$, $\|u\|_{C^1(H^{k+2})}$, and on $\|q\|_{C^1(H^{k+1})}$.

5 Numerical experiments

In this section, we present numerical experiments devised to validate our theoretical predictions from HDG spatial discretizations. To do so, we use the fully discrete CN HDG scheme (8). We take the (uniform) time steps $\delta$ to be sufficiently small so that the HDG and postprocessed HDG spatial discretizations errors are dominant. This is achieved by fixing the ratio $\frac{\delta^2}{h^{k+2}}$ to a given number less than the unit because the time stepping CN scheme is second-order accurate provided that the exact solution is sufficiently regular.

We choose the spatial domain $\Omega$ to be the unit interval $(0, 1)$ and $T = 1$ in (1). We impose homogenous Dirichlet boundary conditions and choose the source term $f$ and the initial data $u_0$ so that the exact solution is $u(x, t) = t^{3-\alpha}sin(\pi x)$. For different values of $\alpha$, we obtain the history of convergence of the errors $\|(u - u_h)(T)\|$, $\|(q - q_h)(T)\|$ and $\|(u - u^*_h)(T)\|$ for different values of the polynomial degree,

| $N$ | $k = 0$ | $k = 1$ | $k = 2$ |
|-----|---------|---------|---------|
|     |         |         |         |
| 4   | 5.269e-01 | 6.031e-02 | 3.960e-03 |
| 8   | 3.027e-01 | 1.502e-02 | 5.059e-04 |
| 16  | 1.616e-01 | 4.144e-03 | 6.352e-05 |
| 32  | 8.342e-02 | 1.048e-03 | 6.352e-05 |
| 64  | 4.237e-02 | 2.697e-04 | 2.993e-05 |
| 128 | 2.135e-02 | 1.958e-04 | 5.652e-05 |

We observe optimal convergence of order $h^{k+1}$ for the errors in $u_h$ and $q_h$, and superconvergence rates of order $h^{k+2}$ (when $k \geq 1$) for the error from the postprocessed HDG solution $u^*_h$. 

Table 1 The errors $\|(u_h - u)(T)\|$, $\|(q_h - q)(T)\|$ and $\|(u^*_h - u)(T)\|$, and the corresponding rates of convergence for $\alpha = 0.5$ with HDG solutions of degree $k = 0, 1, 2$
Table 2 The errors $\|u_h - u\|(T)$, $\|q_h - q\|(T)$ and $\|(u^*_h - u\|(T)$, and the corresponding rates of convergence for $\alpha = 0.7$ with HDG solutions of degree $k = 0, 1, 2$

$k = 0, 1, 2$. To compute the spatial $L_2$-norm, we apply a composite Gauss quadrature rule with 4 points on each interval of the finest spatial mesh. The numerical results (errors and convergence rates) of the experiments are presented in Tables 1 and 2. In full agreement with our theoretical results, we obtain optimal convergence rates for the HDG scheme and $O(h^{k+2})$ superconvergence rates for the postprocessed HDG scheme.
