Abstract

By demanding a compact spectrum for the right-handed neutrinos and an approximate quark-lepton symmetry inspired from $SO(10)$ gauge unification (assuming a Dirac neutrino mass matrix close to the up quark mass matrix), we construct a fine tuning scenario for baryogenesis via leptogenesis. We find two solutions with a normal hierarchy, with the lightest neutrino mass $m_1$ different from zero, providing an absolute scale for the spectrum. In the approximations of the model, there are three independent CP phases: $\delta_L$ (that we take of the order of the quark Kobayashi-Maskawa phase) and the two light neutrino Majorana phases $\alpha$ and $\beta$. A main conclusion is that, although this general scheme is rather flexible, in some regions of parameter space we find that the necessary baryogenesis with its sign is given in terms of the $\delta_L$ phase alone. The light Majorana phases can also be computed and turn out to be close of $\pi/2$ or small. Moreover, $SO(10)$ breaks down to the Pati-Salam group $SU(4) \times SU(2) \times SU(2)$ at the expected natural intermediate scale of about $10^{10} - 10^{11}$ GeV. A prediction is done for the effective mass in $(\beta\beta)_{0\nu}$ decay, the $\nu_e$ mass and the sum of all light neutrino masses.

1 Introduction and qualitative remarks

The discovery of oscillations, advocated so many years ago by Pontecorvo [1], in solar and atmospheric neutrinos is one of the most important experimental discoveries of the last century, the most relevant after the proposal of the Standard Model and its precision tests. The discovery of neutrino oscillations is also a milestone in the search of New Physics (NP).

Up to now four quantities related to the Pontecorvo, Maki, Nagakawa and Sakata (PMNS) matrix [2][3] have been experimentally measured:

\[ \Delta m_s^2 \simeq 8 \times 10^{-5} \text{ eV}^2 \]  \hspace{1cm} (1)
\[ \tan^2 \theta_s \simeq 0.4 \]  \hspace{1cm} (2)
\[ \Delta m_a^2 \simeq 2.5 \times 10^{-3} \text{ eV}^2 \]  \hspace{1cm} (3)
\[ \tan^2 \theta_a \simeq 1 \]  \hspace{1cm} (4)

where the subindices \( s \) and \( a \) mean respectively solar and atmospheric neutrinos.

An upper bound has been been found for the component of \( \nu_{eL} \) along the heaviest \( \nu_L \) mass eigenstate

\[ \sin^2 \theta_{13} < 0.05 \]  \hspace{1cm} (5)

and the limits

\[ m_{\nu_e} < 2.2 \text{ eV} \]  \hspace{1cm} (6)
\[ | < m_{ee} > | < 0.4 \text{ eV} \]  \hspace{1cm} (7)
\[ \sum_i m_{\nu_i} < 1 \text{ eV} \]  \hspace{1cm} (8)

from the high energy spectrum of the electrons in nuclear beta decay, from the upper limit on the rate in neutrinoless double beta decay (for Majorana neutrinos) and from astrophysics.

Interestingly, a more restrictive bound combining all cosmological data has been obtained recently by G. Fogli et al. [4] :

\[ \sum_i m_{\nu_i} < 0.2 \text{ eV} \]  \hspace{1cm} (9)
to which we will refer in Section 8, comparing it to our results.

But for the moment, in this qualitative introduction, we will rely on the generally accepted loser bound [5].

The most natural framework to account for the order of magnitude of neutrino masses is the seesaw model [5], where the $6 \times 6$ neutrino mass matrix has the form

$$
\begin{pmatrix}
0 & m_D^t \\
M & M_R
\end{pmatrix}
$$

(10)

where the $3 \times 3$ Dirac neutrino mass matrix $m_D$ has elements of the order of the masses of charged fermions and $M_R$ is the Majorana mass matrix of the right-handed neutrinos, which are singlets of the Standard Model gauge group, with elements of the order of the scale of breaking of the lepton quantum number.

The information on oscillations gives us only four of the nine parameters of the light neutrino mass matrix. Within the simplifying assumption of neglecting $\theta_{13}$ and consequently the neutrino Dirac CP violating phase, we will be able to strongly constrain the value of its smallest eigenvalue, and fix the values of the two higher ones, as well as the two Majorana phases, simply by demanding that these parameters have a soft dependence on the values of the matrix elements of $M_R$.

We will obtain these results despite the fact that we expect a rather hierarchical spectrum for the eigenvalues of $m_D$, as it happens for the other fermions and as is natural in a $SO(10)$ framework. The mathematical principle is quite simple: it is that the inverse of a function with a critical dependence on a variable is a very slowly varying function: the product of the derivatives is of $O(1)$. The demand of having matrix elements and eigenvalues of $M_R$ of the same order, given a mixing matrix of leptons similar to the one for quarks, will fix $m_1$ and the Majorana phases of light neutrinos. As a result of this requirement, we shall get a compact spectrum for the $N_R$ masses, which will make the leptogenesis scenario for baryogenesis natural, as well as predictions for the electron neutrino mass bounded from tritium $\beta$ decay and the matrix element $| < m_{ee} > |$ appearing in neutrinoless double beta decay.

By compact spectrum for the heavy right-handed neutrinos we simply mean to have eigenvalues of the same order of magnitude.

From the seesaw formula
\[ m_L = -m_D \ M_R^{-1} m_D^t \] (11)

one gets

\[ \det M_R = -\frac{(\det m_D)^2}{\det m_L} \] (12)

From eqn. (8) one obtains the upper limit

\[ | \det m_L | < \frac{1}{27} \ eV^3 \] (13)

while in principle there is no lower limit for the l.h.s. of the inequality (13). Notice that we write the absolute value in the l.h.s. of (13) because neutrino masses, being Majorana masses, can differ in sign for neutrinos with opposite CP.

Moreover, from eqns. (1) and (3) we get:

\[ \Delta m_s^2 = |m_2|^2 - |m_1|^2 \simeq 8 \times 10^{-5} \ eV^2 \] (14)

\[ \Delta m_a^2 = |m_3|^2 - \cos^2 \theta_s |m_2|^2 - \sin^2 \theta_s |m_1|^2 \simeq 2.5 \times 10^{-3} \ eV^2 \] (15)

where the unfamiliar formula (15) for \( \Delta m_a^2 \), proposed in [6], is demonstrated in the Appendix. This formula is an improvement over the usual ones found in the literature, \( \Delta m_a^2 = |m_3|^2 - |m_2|^2 \) or \( \Delta m_a^2 = |m_3|^2 - |m_1|^2 \). Of course, in the limit \( |m_2| \simeq |m_1| \) all these formulas coincide. However, we must underline that the results of this paper are not really sensitive to adopting formula (15) or the usual ones.

From the preceding formula one gets a lower limit for the ratio

\[ \left| \frac{m_2}{m_3} \right| > 0.18 \] (16)

A temptative lower bound for \( | \det m_L | \) may be found in the \( SO(10) \) framework by taking, as in [7],

\[ | \det m_D | = 4 \times 10^{-2} \ GeV^3 \] (17)

and for \( | \det M_R | \) the upper limit

\[ | \det M_R | \leq 2.7 \times 10^{34} \ GeV^3 \] (18)
which comes by assuming that the three right-handed neutrinos take a mass at the scale of $B - L$ spontaneous symmetry breaking in the $SO(10)$ model, with breaking to the $SU(4) \times SU(2) \times SU(2)$ Pati-Salam group [8] at the intermediate scale $3 \times 10^{11}$ |

We then get, from the seesaw formula (12):

$$|\det m_L| \geq 6 \times 10^{-11} \text{eV}^3$$

(19)

Assuming a normal hierarchy for the light neutrinos:

$$|m_2| \sim \sqrt{\Delta m^2_s} \simeq 8.9 \times 10^{-3} \text{eV}$$

(20)

$$|m_3| \sim \sqrt{\Delta m^2_a} \simeq 5.0 \times 10^{-2} \text{eV}$$

(21)

eqn. (19) will then imply the following lower bound for $|m_1|:

$$|m_1| \geq 1.3 \times 10^{-7} \text{eV}$$

(22)

i.e., a non-vanishing value for the lightest neutrino mass $m_1$, an absolute scale for the light neutrino spectrum.

As we will see below, a rather sharp prediction for $m_1$ and relevant predictions for the l.h.s. of eqns. (6)-(8) will be achieved by our demand of a compact $M_R$ spectrum and successful leptogenesis.

The measurements of the cosmic microwave background anisotropies [11] and the abundance of light nuclei produced in primordial nucleosynthesis [12] give a consistent value for the baryon asymmetry:

$$Y_B = \frac{n_B - n_{\bar{B}}}{s} \simeq \frac{1}{7.04} \frac{n_B - n_{\bar{B}}}{n_\gamma} \simeq 9 \times 10^{-11}$$

(23)

This baryonic asymmetry may arise from the leptogenesis scenario [13], with a leptonic asymmetry produced at a high scale, which gives rise by the $B - L$ conserving sphaleron processes [14] at the electroweak scale to a baryon asymmetry below that scale.

Within the leptogenesis scenario, the baryon asymmetry, baryon to entropy fraction, is given by
\[ Y_B \simeq -\frac{1}{2} Y_L \]  

that should be compared with the experimental value given by (23).

Concerning Grand Unification, the \( SU(5) \) minimal model is disfavored, since it generates a small baryon asymmetry at the high scale, washed out at the electroweak scale, since in that model \( B - L \) is conserved. Thus, \( SO(10) \) with its \( B - L \) generator spontaneously broken, that we will adopt in its non-Supersymmetric version, should be preferred to \( SU(5) \) to realize the leptogenesis scenario.

The paper is organized as follows. In Section 2 we give the relevant formulas for the inverse seesaw, mass matrices and mixings. In Section 3 we formulate our \( SO(10) \) Ansatz. In Section 4 we give the formulas needed for \( CP \) violation and the baryon asymmetry. Section 5 is devoted to a simple mathematical procedure to obtain a quasi-degenerate right-handed neutrino spectrum (that presents a level crossing) and a realistic light neutrino spectrum. We underline an illuminating limit of considering, for the matrix diagonalizing \( m_D \), a pure Cabibbo matrix that then we extend to a general matrix of the CKM form, introducing therefore \( CP \) violation. We find two possible solutions. In Section 6 we expose a simple procedure to slowly lift the degeneracy of the heavy right handed neutrinos, and give the corresponding evolution of \( \Delta m_s^2 \) and \( \Delta m_a^2 \). In Section 7 we exhibit the results for \( CP \) violation and baryon asymmetry, in the one-flavor approximation, and in Section 8 we give the predictions for \( m_{\nu_e} \) and the effective neutrino mass in \((\beta\beta)_{0\nu}\). In Section 9 we relax a reality assumption used in Sections 6 and 7. In Section 10 we comment on the compact heavy neutrino spectrum and on the level crossing region. Finally in Sections 11 and 12 we underline open problems within the present approach and we conclude.

2 Inverse seesaw, mass matrices and mixings

From (11), we can deduce the inverse seesaw formula,

\[ M_R = -m_D^T m_L^{-1} m_D \]  

(25)
and diagonalizing the neutrino Dirac mass matrix $m_D$ by

$$m_D = V^{L+} m_D^{\text{diag}} V^R$$  \hspace{1cm} (26)$$

one gets the formula [6]

$$M_R = -m_D^t m_L^{-1} m_D = -V^{Rt} m_D^{\text{diag}} V^{L*} m_L^{-1} V^{L+} m_D^{\text{diag}} V^R$$

$$= -V^{Rt} m_D^{\text{diag}} A^L m_D^{\text{diag}} V^R$$  \hspace{1cm} (27)$$

where the last equality follows from the definition [6] of the matrix $A^L$

$$A^L = V^{L*} m_L^{-1} V^{L+}$$  \hspace{1cm} (28)$$

The neutrino mass matrix $m_L$ is diagonalized by the PMNS matrix $U$ :

$$m_L = U^{*} m_L^{\text{diag}} U^+$$  \hspace{1cm} (29)$$

where

$$m_L^{\text{diag}} = \text{diag}(m_1, m_2, m_3)$$  \hspace{1cm} (30)$$

and $U$ writes :

$$U = \begin{pmatrix}
  c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\
  -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\
  s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13}
\end{pmatrix} \cdot \text{diag}(1, e^{i\alpha}, e^{i\beta})$$  \hspace{1cm} (31)$$

where $\delta$ is the Dirac phase and $\alpha$ and $\beta$ are the Majorana phases. For the latter we adopt the convention of Davidson et al. [13].

Let us make a remark on the counting of phases. One has, in all generality, 6 independent phases in the Type I seesaw scheme, as established in [13][16] and as it is exposed in the review [13] (last reference, Section 2.1). In the model that we develop below, the number of independent phases will be reduced according to the hypotheses adopted.

Taking into account the data on solar and atmospheric neutrinos and the fact that $s_{13}$ is bounded to be small, we will take
and approximate, from now on, the matrix $U$ as follows:

$$
U \simeq \begin{pmatrix}
    c_s & s_s & 0 \\
    -\frac{s_s}{\sqrt{2}} & c_s & \frac{1}{\sqrt{2}} \\
    \frac{s_s}{\sqrt{2}} & -\frac{c_s}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{pmatrix} \, \text{diag}(1, e^{i\alpha}, e^{i\beta})
$$

(33)

and CP violation originating in the Dirac phase $\delta$ drops out.

To simplify the expressions in what follows, we change the notation for the diagonal matrix in (29)-(31)

$$
\text{diag}(m_1, e^{-2i\alpha} m_2, e^{-2i\beta} m_3) \rightarrow \text{diag}(m_1, m_2, m_3)
$$

(34)

where, from now on, $m_2$ and $m_3$ are assumed to be complex parameters.

Eqn. (29) now writes, in the approximation (33), and with the notation convention of the r.h.s. of (34):

$$
m_L \simeq \begin{pmatrix}
    c_s & s_s & 0 \\
    -\frac{s_s}{\sqrt{2}} & c_s & \frac{1}{\sqrt{2}} \\
    \frac{s_s}{\sqrt{2}} & -\frac{c_s}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{pmatrix} \, \text{diag}(m_1, m_2, m_3) \begin{pmatrix}
    c_s & -\frac{s_s}{\sqrt{2}} & \frac{s_s}{\sqrt{2}} \\
    s_s & \frac{c_s}{\sqrt{2}} & -\frac{c_s}{\sqrt{2}} \\
    0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{pmatrix}
$$

(35)

Let us strongly underline again that in (35), and in what follows, the parameters $m_2, m_3$ are assumed to be complex, containing, according to (34), the Majorana phases defined by (31).

These phases will be computed at different stages. Their calculation will depend on some hypotheses to be made explicit below, and on the successive parametrizations assumed for the matrix $m_D$ (26).

From the previous hypotheses we obtain the following complex symmetric matrix

$$
m_L^{-1} = \begin{pmatrix}
    \frac{s_s^2}{m_1^2} + \frac{s_s^2}{m_2^2} & -\frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) & \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) \\
    -\frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) & \frac{1}{2} \left( \frac{s_s^2}{m_1} + \frac{c_s^2}{m_2} + \frac{1}{m_3} \right) & -\frac{1}{2} \left( \frac{s_s^2}{m_1} + \frac{c_s^2}{m_2} - \frac{1}{m_3} \right) \\
    \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) & -\frac{1}{2} \left( \frac{s_s^2}{m_1} + \frac{c_s^2}{m_2} - \frac{1}{m_3} \right) & \frac{1}{2} \left( \frac{s_s^2}{m_1} + \frac{c_s^2}{m_2} + \frac{1}{m_3} \right)
\end{pmatrix}
$$

(36)

and the matrix $A_L$ (28) is also complex symmetric.
\[ A^{L*} = A^L \]  

(37)

In a previous work [6], to comply with the lower bound for the mass of the lightest right-handed neutrino claimed by [17], we did set upper limits on the coefficients of contributions proportional to the products of the Dirac matrix eigenvalues \((m_D^3)^2\) and \(m_D^2 m_D^3\) in the \(M_R\) matrix, related to \(m_L\) by the inverse seesaw formula.

From formula (27) we see that to get a quasi-degenerate heavy Majorana neutrino spectrum we need that the terms proportional to \((m_D^3)^2\) and \(m_D^2 m_D^3\) to have to be small, that means for a hierarchical Dirac mass spectrum that the matrix elements of \((\nu)^{L*}\) \(A_{33}\) and \(A_{23} = A_{32}\) have to be small. From (28), we get the following expression for these matrix elements of interest:

\[
A_{23}^L = V_{31}^L \left[ \left( \frac{c_s^2}{m_1} + \frac{s_s^2}{m_2} \right) V_{21}^{L*} - \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) V_{22}^{L*} + \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) V_{23}^{L*} \right]
\]

(38)

\[
A_{33}^L = V_{31}^L \left[ \left( \frac{c_s^2}{m_1} + \frac{s_s^2}{m_2} \right) V_{31}^{L*} - \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) V_{32}^{L*} + \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) V_{33}^{L*} \right]
\]

(39)

3 Our \(SO(10)\) Ansatz

The seesaw model is realized in the framework of \(SO(10)\) unified gauge theories [18], where \(B - L\) is a generator, which has to be spontaneously broken. Long time
before the firm evidence for neutrino oscillations this phenomenon had been claimed \[19\] as the most promising experimental signal for \(SO(10)\) unification.

A systematic study of the spontaneous symmetry breaking in \(SO(10)\) unified theories has lead to propose \[9\] the model with \(SU(4) \times SU(2) \times SU(2)\) \[8\] intermediate gauge group, broken at the scale of order \(3 \times 10^{11} \text{ GeV}\) \[10\].

A general analysis has been done in \[7\] on the possibility to construct a realistic leptogenesis scenario within the seesaw model with neutrino Dirac masses in a hierarchical ratio, as it is the case for u-type quarks. The most promising case has been found with \(M_3 \sim 10^{14} \text{ GeV}\) and nearby values for the masses of the two lightest right-handed neutrinos.

Although in the present paper we follow the general idea \[7\] of leptogenesis generated by quasi-degenerate right-handed neutrinos, we look for a more compact spectrum for \(N_R\), with the heaviest right-handed neutrino at the intermediate scale, of the order \(10^{11} \text{ GeV}\).

In \(SO(10)\) the hypothesis that the electroweak Higgs transforms as a combination of \(10\) representations implies at the unification scale the equalities among mass matrices

\[
m_e = m_d \tag{40}
\]

\[
m_D = m_u \tag{41}
\]

For \(b\) and \(\tau\) masses relation \(40\) at the intermediate scale is in reasonable agreement with experiment but, as Georgi and Jarlskog \[20\] have shown in the \(SU(5)\) case, one needs also higher dimensional representations. The generalization of this argument to \(SO(10)\) was given by Harvey et al. \[21\]. For an overview on fermion masses and mixings in gauge theories, see the review article \[22\].

Within \(SO(10)\), with the electroweak Higgs boson belonging to the \(10\) and/or \(126\) representations, and \textit{no component along the 120 representation}, the mass matrices are symmetric. As a consequence, the unitary matrices \(V^R\) and \(V^L\) that diagonalize Dirac neutrino matrix \[26\] are related:

\[
V^R = V^L* \tag{42}
\]

and the matrix \(M_R\) \[27\] becomes

\[
M_R = -m_D^L m_L^{-1} m_D = -V^{L+} m_D^{diag} V^{L*} m_L^{-1} V^{L+} m_D^{diag} V^{L*} \\
= -V^{L+} m_D^{diag} A^L m_D^{diag} V^{L*}
\] (43)

Let us now go back to the question of the phase counting, quoted for the seesaw scheme in Section 3, in the particular case of \(SO(10)\) with symmetric Dirac neutrino matrix. Since \(V^L\) has only one phase, and \(m_L\), through the mixing matrix \(U\) \(31\) has three phases, we have reduced the number of independent phases, from 6 in the general case to 4 independent phases. In the approximation \(32\) \(s_{13} \approx 0\) that we have adopted, this means that we have 3 independent phases, namely a phase from \(V^L\), that we will call \(\delta_L\), and the two Majorana phases \(\alpha\) and \(\beta\) from \(33\).

Below, in Sections 5 and 6, we will impose two other conditions that reduce further the number of independent phases, from 3 to a single one.

For the diagonalized Dirac neutrino matrix

\[
m_D^{diag} = \begin{pmatrix}
m_D, & 0 & 0 \\
0, & m_D, & 0 \\
0, & 0, & m_D
\end{pmatrix}
\] (44)

we will adopt the numerical values proposed in \[7\], inspired from the up-quark mass matrix:

\[
m_D^1 = 10^{-3} \text{ GeV} \quad m_D^2 = 0.4 \text{ GeV} \quad m_D^3 = 100 \text{ GeV}
\] (45)

The matrix \(m_D^{diag} A^L m_D^{diag}\) appearing in \(27\) has the form

\[
m_D^{diag} A^L m_D^{diag} = \begin{pmatrix}
m_D^1, A_{11}^L, m_D^1 m_D^2 A_{12}^L, m_D^1 m_D^3 A_{13}^L \\
m_D^2, m_D^2 A_{12}^L, m_D^2 A_{22}^L, m_D^2 m_D^3 A_{23}^L \\
m_D^3, m_D^3 A_{13}^L, m_D^3 m_D^3 A_{23}^L, m_D^3 A_{33}^L
\end{pmatrix}
\] (46)

that clearly shows that in order to have a compact \(N_R\) spectrum from \(27\) one needs small values for the matrix elements \(A_{23}^L\) and \(A_{33}^L\).

For \(V^L\) we will assume a form qualitatively similar to the Cabibbo-Kobayashi-Maskawa (CKM) quark matrix, that reads, in the standard convention (except for the phase \(\delta_L\), we take the same notation as for the light neutrino mixing matrix \(31\), but in what follows there is no ambiguity):

\[
\frac{11}{11}
\]
where $\delta_L$ is the CP-violating phase.

Formula (47) is correct at least for exact quark-lepton symmetry, with Higgs in the 10 representation: if the mass matrices (40) are diagonal and real one has $V^L = V_{CKM}$. For phenomenological purposes we assume this form in what follows.

We define, as usual, in terms of Wolfenstein parameters:

$$s_{12} = \lambda$$
$$s_{23} = A\lambda^2$$
$$s_{13}e^{i\delta_L} = A\lambda^3(\rho + i\eta)$$

Of course, in our problem the parameters $\lambda, A, \rho, \eta$ do not necessarily have the same precise values as in the quark sector: we are interested only in an order of magnitude estimate.

Let us say some words concerning the diagonalization of the right-handed neutrino matrix. Since in our $SO(10)$ Ansatz $M_R$ (43) is complex and symmetric, we can diagonalize it by using a single unitary matrix:

$$M_R = W_R M_R^{\text{diag}} W_R^t$$  \hspace{1cm} (49)

The matrix $W_R$ is such that all eigenvalues are real and positive. The effect of phases will appear in the matrix $W_R$. These phases will of course have consequences for baryogenesis and for neutrinoless double beta decay.

As we will see below, our demand of suppressed values for $A_{33}^L$ and $A_{23}^L$ generates a compact form for the $M_R$ spectrum, which helps in getting in a natural way the desired lepton asymmetry.

\section{Leptogenesis and baryon asymmetry}

In this Section we recall the basic formulas concerning the CP violating asymmetry $\epsilon_1$ and the corresponding baryogenesis asymmetry $Y_{B_1}$. We work in the basis
in which the mass matrices of charged leptons and of right-handed neutrinos are diagonal, i.e. from (25) and (49):

\[ M_{R}^{\text{diag}} = -W_{R}^{+} m_{D}^{t} m_{L}^{-1} m_{D} W_{R}^{*} \]  

(50)

Therefore, in the computation of the CP-violating asymmetry \( \epsilon_{1} \) we define

\[ \hat{m}_{D} = m_{D} W_{R}^{*} \]  

(51)

such that

\[ M_{R}^{\text{diag}} = -\hat{m}_{D}^{4} m_{L}^{-1} \hat{m}_{D} \]  

(52)

By convention we label the masses of the heavy neutrinos \( N_{R_{i}} \) (i = 1, 2, 3):

\[ 0 \leq M_{1} \leq M_{2} \leq M_{3} \]  

(53)

In terms of \( \hat{m}_{D} \), the CP asymmetry writes, for the lightest heavy neutrino \( N_{R_{1}} \):

\[ \epsilon_{1} = \frac{1}{8 \pi v^{2}} \sum_{k \neq 1} f \left( \frac{M_{k}^{2}}{M_{1}^{2}} \right) \text{Im} \left( (\hat{m}_{D}^{+}\hat{m}_{D})_{ik} \right) \]  

(54)

where \( v = 174 \text{ GeV} \) is the scale of electroweak symmetry breaking, and the function \( f(x) \) is given by [23] :

\[ f(x) = \sqrt{x} \left[ \frac{1}{1 - x} + 1 - (1 + x) \log \left( \frac{1 + x}{x} \right) \right] \]  

(55)

that in the limit \( x \gg 1 \) becomes:

\[ f(x) \simeq -\frac{3}{2 \sqrt{x}} \]  

(56)

and the effective neutrino mass, that controls the amount of washout, writes:

\[ \tilde{m}_{1} = \frac{(\hat{m}_{D}^{+}\hat{m}_{D})_{11}}{M_{1}} \]  

(57)

The cases that we encounter in our calculations below satisfy the strong washout condition

\[ \tilde{m}_{1} \gg 3 \times 10^{-3} \text{ eV} \]  

(58)
and the corresponding baryon asymmetry writes, in the one-flavor approximation, that we will adopt in the following [24]:

\[ Y_{B_1} = -\frac{1}{2} 0.3 \frac{\epsilon_1}{g_*} \left( \frac{0.55 \times 10^{-3} eV}{\bar{m}_1} \right)^{1.16} \]  

(59)

where \( g_* \simeq 107 \) in the Standard Model, in the non-Supersymmetric case.

5 Quasi-degenerate heavy right-handed neutrinos and realistic light neutrino spectrum

In order to get a compact \( N_R \) spectrum, a sufficient condition is to impose that the matrix elements \( A_{33}^L \) and \( A_{23}^L \) are suppressed, because we are dealing with the matrix (46) and the \( m_D \) eigenvalues (45). As a first exercise, we thus consider the solutions of the equations, linear and homogeneous in the inverse of the neutrino masses \( \frac{1}{m_i} (i = 1, 2, 3) \),

\[ A_{23}^L(m_1, m_2, m_3) = A_{33}^L(m_1, m_2, m_3) = 0 \]  

(60)

We are aware that this is a very drastic assumption, but will help to guide our research of a compact right-handed neutrino spectrum, and also to look for its consequences on the light neutrino masses and the amount of baryogenesis that one can get. We must emphasize that in this Section, and in the following ones, we are dealing with a fine tuning scheme. We cannot content ourselves with just order-of-magnitude estimates, but we need precise numerical calculations.

Notice a new important point in the phase counting of eqn. (43) with the hypothesis (32). Under the two reality conditions (60) that we now impose, the 3 phases (see Section 3) are now reduced to a single phase, either \( \delta_L \) or one of the two Majorana phases \( \alpha \) or \( \beta \).

Since we do not have experimental information on the Majorana phases, we will, from now on, compute \( \alpha \) and \( \beta \), and later the CP asymmetry \( \epsilon_1 \) and baryon asymmetry \( Y_{B_1} \) in terms of \( \delta_L \). Of course, in principle one could also compute the pair \( (\delta_L, \alpha) \) in terms of \( \beta \) or \( (\delta_L, \beta) \) in terms of \( \alpha \). But in the present \( SO(10) \)
approach the natural thing to do is to take as input $\delta_L$, since we can take it to be of the order of Kobayashi-Maskawa (KM) phase $\delta_{KM}$, on which we have information.

5.1 $V^L$ in the limit of a pure Cabibbo matrix

For our purpose, it is a good illustration to study the consequences of this hypothesis considering it within the very simplified approximation of a $2 \times 2$ Cabibbo matrix

$$V^L = \begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (61)$$

Since from (61) $\delta_L$ drops out, we are left with only two phases, namely the Majorana phases $\alpha$ and $\beta$. Imposing the two reality conditions (60), these phases will be fixed, as we see below.

From (60) and (61), we find that the light and heavy neutrino spectra turn out to be reasonable. From (38)(39), the matrix elements of $A^L$ we are interested in are

$$A^L_{23} = A^L_{32} = -\frac{1}{2} \left( \frac{s^2_s}{m_1} + \frac{c^2_s}{m_2} - \frac{1}{m_3} \right) c_{12} - \frac{c_s s_s}{\sqrt{2}} \left( \frac{1}{m_1} - \frac{1}{m_2} \right) s_{12}$$

$$A^L_{33} = \frac{1}{2} \left( \frac{s^2_s}{m_1} + \frac{c^2_s}{m_2} + \frac{1}{m_3} \right) \quad (62)$$

If we impose the very strong assumption (60) we have the two equations

$$\frac{s^2_s}{m_1} + \frac{c^2_s}{m_2} - \frac{1}{m_3} + \sqrt{2} c_s s_s \left( \frac{1}{m_1} - \frac{1}{m_2} \right) \tan \theta_{12} = 0$$

$$\frac{s^2_s}{m_1} + \frac{c^2_s}{m_2} + \frac{1}{m_3} = 0 \quad (63)$$

and solving for $m_2$ and $m_3$ in terms of $m_1$, one gets:

$$m_2 = -\frac{\sqrt{2} - \tan \theta_s \tan \theta_{12}}{\sqrt{2} \tan^2 \theta_s + \tan \theta_s \tan \theta_{12}} m_1$$

$$m_3 = \frac{\sqrt{2} - \tan \theta_s \tan \theta_{12}}{\tan \theta_s \tan \theta_{12}} m_1 \quad (64)$$

From the data (1)-(4) and formulas (14)(15) one gets, from (64), a number of solutions for $m_1$ and $\theta_{12}$.
However, if one looks for solutions with $\theta_{12}$ in the neighborhood of the Cabibbo angle $\theta_C$, one finds the following solutions, according to the sign of $\tan \theta_s$, since only its square $|2|$ is measured:

(1) For $\tan \theta_s \simeq -\sqrt{0.4}$ one gets,

$$\tan \theta_{12} = 0.140$$  \hspace{1cm} (65)

$$|m_1| = 0.0030 \text{ eV} \hspace{1cm} m_2 = -3.1522 \ m_1 \hspace{1cm} m_3 = -16.9273 \ m_1$$  \hspace{1cm} (66)

We have taken several digits for the $m_i$ values to get a compact spectrum for the $N_{R_i}$ and, as we will see below, for later to obtain the non-degeneracy of the two higher states. The reason is that we are dealing with a fine-tuning problem. Of course, one could take the first digits and say the degree of approximation at each stage, but we believe that our way of presenting the results, although harder to read, corresponds better to the reality of the calculation.

In consistency with (34) we assume the convention $m_1 > 0$ and one gets the following spectrum

$$m_1 = 0.0030 \text{ eV} \hspace{1cm} m_2 = -0.0094 \text{ eV} \hspace{1cm} m_3 = -0.0507 \text{ eV}$$  \hspace{1cm} (67)

where two heavier neutrinos have opposite CP from the lighter one. This means that the Majorana phases are

$$\alpha = \frac{\pi}{2} \hspace{1cm} \beta = \frac{\pi}{2}$$  \hspace{1cm} (68)

We find, from (26), (42) and the value $\tan \theta_{12}$ (65), for the symmetric Dirac mass matrix:

$$m_D = \begin{pmatrix} 0.0087 & -0.0549 & 0 \\ -0.0549 & 0.3923 & 0 \\ 0 & 0 & 100 \end{pmatrix} \text{ GeV}$$  \hspace{1cm} (69)

and

$$M_1 = 5.5504 \times 10^9 \text{ GeV} \hspace{1cm} M_2 = 1.42991 \times 10^{10} \text{ GeV} \hspace{1cm} M_3 = 1.42992 \times 10^{10} \text{ GeV}$$  \hspace{1cm} (70)

(2) For $\tan \theta_s \simeq +\sqrt{0.4}$ one gets
\[ \tan \theta_{12} = 0.243 \]  
\[ |m_1| = 0.0062 \text{ } eV \quad m_2 = -1.752 \quad m_3 = 8.191 \quad m_1 \]  

Assuming again the convention \( m_1 > 0 \) one gets the following hierarchical spectrum

\[ m_1 = 0.0062 \text{ } eV \quad m_2 = -0.0109 \text{ } eV \quad m_3 = 0.0509 \text{ } eV \]  

where two neutrinos (the lightest and the heaviest) have opposite CP from the third one. This means that the Majorana phases are

\[ \alpha = -\frac{\pi}{2} \quad \beta = 0 \]  

We obtain for this solution, from the value \( \tan \theta_{12} \) (71), the Dirac neutrino matrix

\[ m_D = \begin{pmatrix} 0.0233 & -0.0916 & 0 \\ -0.0916 & 0.3777 & 0 \\ 0 & 0 & 100 \end{pmatrix} \text{GeV} \]  

and the quasi-degenerate right-handed heavy neutrino spectrum:

\[ M_1 = 6.72168 \times 10^9 \text{GeV} \quad M_2 = 8.30366 \times 10^9 \text{GeV} \quad M_3 = 8.30409 \times 10^9 \text{GeV} \]  

The results for these two solutions seem encouraging because we get in both cases a value of the angle \( \theta_{12} \) that is rather close to the Cabibbo angle \( \theta_C \). It seems highly non-trivial and amazing that such a simplified form of the \( V^L \) matrix could give already these results consistent with quark-lepton symmetry.

### 5.2 \( V^L \) with approximate CKM form

We now switch on the other \( V^L \) parameters and consider the full matrix (47). To perform the calculations we adopt for \( m_1 \) and \( \tan \theta_{12} \) the values obtained in the pure Cabibbo limit, namely \( m_1 = 0.0030 \text{ } eV, \tan \theta_{12} = 0.140 \) for solution (1) and \( m_1 = 0.0062 \text{ } eV, \tan \theta_{12} = 0.243 \) for solution (2).

For the numerical calculations we thus proceed in the following way:
i) From either solution (1) or solution (2) of the preceding Subsection, we fix the parameters $m_1$ and $\tan \theta_{12}$:

(1) $\tan \theta_s = -\sqrt{0.4}$ \quad $m_1 = 0.0030 \text{ eV}$ \quad $\tan \theta_{12} = 0.140 \quad (77)$

(2) $\tan \theta_s = +\sqrt{0.4}$ \quad $m_1 = 0.0062 \text{ eV}$ \quad $\tan \theta_{12} = 0.243 \quad (78)$

ii) For the rest of the $V_L$ matrix elements we deduce the Wolfenstein parameter $\lambda$ in (48) from (77) and (78) and take, just a guess, the parameters $A$, $\rho$ and $\eta$ from the quark sector CKM matrix, i.e. for example

$$A = 0.8 \quad \rho = 0.13 \quad \eta = 0.35 \quad (79)$$

and, using these parameters, we fix $s_{23}, s_{13}$ following (48):

(1) $\tan \theta_{12} = 0.140$, \quad $s_{23} = 0.0154$, \quad $s_{13} = 0.0008$, \quad $\delta_L = 1.2152 \quad (80)$

gives

$$V^L \approx \begin{pmatrix} 0.990 & 0.139 & (2.8 - 7.5i) \times 10^{-4} \\ -0.139 & 0.990 & 0.015 \\ (18.6 - 7.4i) \times 10^{-4} & -0.015 & 1. \end{pmatrix} \quad (81)$$

while from

(2) $\tan \theta_{12} = 0.243$, \quad $s_{23} = 0.0446$, \quad $s_{13} = 0.0039$, \quad $\delta_L = 1.2152 \quad (82)$

one obtains

$$V^L \approx \begin{pmatrix} 0.972 & 0.236 & (1.37 - 3.68i) \times 10^{-3} \\ -0.236 & 0.971 & 0.045 \\ (9.20 - 3.58i) \times 10^{-3} & -0.044 & 1. \end{pmatrix} \quad (83)$$

iii) Then, we solve equations (60) for $m_2$ and $m_3$ and compare with experiment for $\Delta m^2_s$ and $\Delta m^2_a$.

Notice that this numerical procedure is less rigid that the one adopted in the simpler case of a pure Cabibbo matrix of the preceding Subsection, where $\Delta m^2_s$ and $\Delta m^2_a$ were fixed to the experimental central values (1)(3) and we did solve for $\tan \theta_{12}$, $m_1$, $m_2$ and $m_3$. We prefer to change here our numerical approach due to
the extreme fine tuning of the problem. It seems to us sensible enough if we get results for $\Delta m_s^2$ and $\Delta m_a^2$ that are roughly consistent with experiment.

We find the following results.

(1) For $\tan \theta_s \simeq -\sqrt{0.4}$, $m_1 = 0.0030 \ eV$ and $\tan \theta_{12} = 0.140$, one gets:

$$m_2 = -0.0095 \ eV, \ m_3 = -0.0495 \ eV$$

that correspond to the Majorana phases

$$\alpha = \frac{\pi}{2} - 0.0018, \ \ \ \beta = \frac{\pi}{2} - 0.0038$$

Let us notice an important point. We obtain the CP violating part of the Majorana phases for the light neutrinos (i.e. their departure relatively to $\frac{\pi}{2}$ in (85)) from the $\delta_L$ phase, that we take close to the KM phase $\delta_{KM}$. This can seem paradoxical, because $\delta_L$ concerns the Dirac neutrino mass. However, because of $\delta_L$, the matrix $A_L$ is complex. This implies that, setting $m_1$ real as we have done above, the solutions from eqns. (60) for $m_2$ and $m_3$ (with the notation (34)) must be complex. The departure of these Majorana phases relatively to the ones obtained in the real Cabibbo limit (68)(74) turn out to be numerically small.

We obtain, from (14)(15) and (84) :

$$\Delta m_s^2 = 8.1 \times 10^{-5} \ eV^2, \ \ \ \Delta m_a^2 = 2.4 \times 10^{-3} \ eV^2$$

The agreement with the data is good.

Let us now give the complex symmetric Dirac neutrino mass and the right-handed heavy neutrino spectrum for this solution. We get

$$m_D = \begin{pmatrix}
0.0090 + 0.0003i & -0.0576 - 0.0011i & 0.1849 + 0.0739i \\
-0.0576 - 0.0011i & 0.4155 - 0.0003i & -1.5206 + 0.0103i \\
0.1849 + 0.0739i & -1.5206 + 0.0103i & 99.9764
\end{pmatrix} \ \ \ \ GeV$$

and the quasi-degenerate right-handed heavy neutrino spectrum :

$$M_1 = 5.53144 \times 10^9 \ GeV, \ \ M_2 = 1.43230 \times 10^{10} \ GeV, \ \ M_3 = 1.43232 \times 10^{10} \ GeV$$
(2) For $\tan \theta_s \simeq +\sqrt{0.4}$, $m_1 = 0.0062$ eV and $\tan \theta_{12} = 0.243$ one gets:

$$m_2 = -0.0106 \ e^{-0.016i} \ eV \quad m_3 = 0.0455 \ e^{0.0078i} \ eV$$

that correspond to the Majorana phases

$$\alpha = -\frac{\pi}{2} + 0.0080 \quad \beta = -0.0039$$

We obtain, from (14)(15) and (89):

$$\Delta m^2_s = 7.4 \times 10^{-5} \ eV^2 \quad \Delta m^2_a = 2.0 \times 10^{-3} \ eV^2$$

The agreement with the data is not as good as for solution (1). We could change the initial conditions for $m_1$ and $\tan \theta_{12}$ and get a better agreement. However, it is not our intention to make a fit but to get a qualitative agreement with the data.

We get the Dirac matrix for this solution

$$m_D = \begin{pmatrix}
0.0304 + 0.0066i & -0.1319 - 0.0148i & 0.9152 + 0.3575i \\
-0.1319 - 0.0148i & 0.5676 - 0.0076i & -4.3450 + 0.0869i \\
0.9152 + 0.3575i & -4.3450 + 0.0869i & 99.8003
\end{pmatrix} \ \text{GeV}$$

and the quasi-degenerate right-handed heavy neutrino spectrum:

$$M_1 = 6.84678 \times 10^9 \ GeV \quad M_2 = 8.84878 \times 10^9 \ GeV \quad M_3 = 8.84909 \times 10^9 \ GeV$$

The signs and phases of the results (84) and (89) will have quantitative consequences for the effective neutrino mass in neutrinoless double beta decay, as we will see below.

5.3 CP violation and baryon asymmetry

The results of the preceding Subsection show that imposing the very drastic conditions (60) one gets quasi-degenerate right-handed neutrino spectra.

To have a feeling on how to proceed, let us make an exercise in the case (1), where the quasi-degeneracy (88) is less pronounced. Let us compute the Dirac matrix (51) in the basis in which the heavy right-handed neutrino mass matrix is diagonal, $\epsilon_1$, $\tilde{m}_1$
and finally $Y_{B_1}$. We will assume that the lightest neutrino decays out-of-equilibrium and that one can apply the one-flavor approximation.

We find the following result

$$
\hat{m}_D \simeq \begin{pmatrix}
-0.055i & -0.052 + 0.132i & -0.131 - 0.052i \\
-0.001 + 0.391i & -0.006 - 1.081i & 1.080 - 0.006i \\
-0.002 + 0.347i & -0.064 + 70.702i & -70.702 - 0.064i
\end{pmatrix} \text{ GeV}
$$

Of course, unlike expression (87), this matrix is no longer symmetric. Using it in eqns. (54), (57) and (59), we obtain

$$
\epsilon_1 \simeq -3.805 \times 10^{-10} \quad \tilde{m}_1 \simeq 0.050 \text{ eV} \quad Y_{B_1} \simeq 3.05 \times 10^{-15}
$$

where we have used the exact formula (55) for the function $f(x)$ since the three heavy neutrinos are rather close in mass, although $N_{R_1}$ is lighter, and formula (59) is applied because, according to the value of $\tilde{m}_1$ (95), we are in the strong washout regime (58).

The obtained baryon asymmetry $Y_{B_1} \simeq 3 \times 10^{-15}$ is much too small, by about four to five orders of magnitude, although of the right sign. The reason is the smallness of $\epsilon_1$, that follows from the quasi-degeneracy of $M_2$ and $M_3$ and the opposite $CP$ asymmetry contribution from both heavy neutrinos. Indeed one finds, for the two terms in (54) :

$$
f \left( \frac{M_2^2}{M_1^2} \right) \frac{\text{Im} \left[ (\hat{m}_D \hat{m}_D^+)_2 \right]}{8\pi v^2 (\hat{m}_D \hat{m}_D^+)_1} \simeq -f \left( \frac{M_3^2}{M_1^2} \right) \frac{\text{Im} \left[ (\hat{m}_D \hat{m}_D^+)_3 \right]}{8\pi v^2 (\hat{m}_D \hat{m}_D^+)_1} \simeq -3.634 \times 10^{-6}
$$

that shows a strong cancellation giving a very small $CP$ violation $\epsilon_1$.

Although for the moment we do not get good phenomenological results, we should however emphasize an interesting limit of the present scheme, namely :

$$
\delta_L \to 0 \quad \text{implies} \quad \epsilon_1 \to 0 \quad Y_{B_1} \to 0
$$

$$
\alpha = \beta \to \frac{\pi}{2} \quad \text{(solution (1))} \quad \alpha \to -\frac{\pi}{2}, \quad \beta \to 0 \quad \text{(solution (2))}
$$

Notice that we have an intuitive argument to understand the quasi-degeneracy between $M_2$ and $M_3$ (88) and the smallness of the $CP$ violation (95). Indeed, in the
limit \( A_{23}^{L} = A_{33}^{L} = 0 \) (60), and neglecting terms of order \( m_{D_{1}}^{2} \) and \( m_{D_{1}}m_{D_{2}} \), since we take \( V^L \) to be close to a diagonal matrix, the \( M_{R} \) matrix has only \( M_{R_{13}} \), \( M_{R_{31}} \) and \( M_{R_{22}} \) sizeable matrix elements with \( M_{R_{13}} \simeq M_{R_{31}} \), and the matrix \( M_{R} \) is close to real. Therefore one has \( M_{2} \simeq M_{3} \) and \( \epsilon_{1} \simeq 0 \).

We can try to modify our very simplified scheme by lifting the degeneracy of \( N_{R_{2}} \) and \( N_{R_{3}} \). We will thus relax somewhat the strong condition (60), but keeping the general physical idea of a compact heavy \( N_{R} \) spectrum. We will allow for non-vanishing values for the matrix elements \( |A_{23}^{L}| \) and \( |A_{33}^{L}| \), keeping them ”small”, i.e. values much smaller than each of their individual contributions that, due to the smallness of the light neutrino masses, are naturally of the order \( \sim 10^{11} \text{ GeV}^{-1} \), as can be seen in eqns. (38) (39).

As we will further examine, one can thus obtain a rather compact \( N_{R} \) spectrum, and also reasonable values for the baryon asymmetry consistent with the data without spoiling the good properties of the light neutrino spectrum.

6 Lifting the quasi-degeneracy of heavy neutrinos

We will proceed now, in terms of some parameters, to a continuous and slow lifting of the quasi-degeneracy of the heavy right-handed neutrino masses obtained in the previous Section within the strong hypothesis (60).

In this Section we do the calculation considering non-vanishing values for the r.h.s. of the eqns. (60). Moreover, since we have seen that even the drastic assumption of taking \( A_{33}^{L} = A_{23}^{L} = 0 \) gives reasonable neutrino spectra (84) or (89), we will allow to vary \( |A_{23}^{L}| \) and \( |A_{33}^{L}| \) within a very wide range, keeping ”small” values \( (\ll 10^{11} \text{ GeV}^{-1}) \), and observe how the heavy neutrino and the light neutrino spectra evolve, as well as the consequences for the \( CP \) violation asymmetry \( \epsilon_{1} \), the effective neutrino mass \( \hat{m}_{1} \) and baryon asymmetry \( Y_{B_{1}} \). We will perform the calculations for both solutions (1) \( (\tan \theta_{s} \simeq -\sqrt{0.4}) \) and (2) \( (\tan \theta_{s} \simeq +\sqrt{0.4}) \).

Notice that the strong conditions (60) \( A_{33}^{L} = A_{23}^{L} = 0 \) are linear homogeneous equations in \( \frac{1}{m_{i}} \) \( (i = 1, 2, 3) \). We now allow for non-vanishing inhomogeneous terms
To lift the very close degeneracy between $M_2$ and $M_3$ in the case examined before, $A_{23}^L = A_{33}^L = 0$, we just need to have non-vanishing, in general complex parameters $C_{23}^L$ and $C_{33}^L$ in the r.h.s. of (98) and (99). However, to have an overall compact heavy neutrino spectrum we need inhomogeneous terms that should be small in modulus relatively to each individual term in $A_{23}^L$ and $A_{33}^L$ (38)-(39). This means that we will take non-vanishing values for $C_{23}^L$ and $C_{33}^L$ with the condition

$$|C_{23}^L|, |C_{33}^L| \ll 10^{11} \text{ GeV}^{-1}$$

In principle one should scan the general two complex numbers $C_{23}^L$ and $C_{33}^L$ and see how the heavy neutrino spectrum evolves, as well as the light neutrino masses, the light neutrino Majorana phases $\alpha$ and $\beta$, the CP asymmetry $\epsilon_1$ and final baryon asymmetry $Y_{B_1}$.

As pointed out at the beginning of Section 5, the Majorana phases (85) and (90), that we found for $C_{23}^L = C_{33}^L = 0$ have their origin in the approximation adopted for the matrix $V^L$, that we take close to the CKM matrix. In order to preserve this interesting feature, we will assume that the non-vanishing values of the inhomogeneous terms $C_{23}^L$ and $C_{33}^L$ are real and satisfy (100). Later, in Section 9 we will relax this reality assumption and will see that we have a wide domain of values for complex $C_{23}^L$ and $C_{33}^L$ that can give reasonable results.

The first important observation to be made is that the degeneracy between $N_{R_2}$ and $N_{R_3}$, that we have found solving eqns. (60) is lifted considerably if $|C_{33}^L|$ is non vanishing in some region with $|C_{33}^L| \ll 10^{11} \text{ GeV}^{-1}$, and we have realized that the mass difference $M_3 - M_2$ is rather insensitive to the precise value of $|C_{23}^L|$, provided that its value is not "too large". Importantly, the amount of CP violation, and therefore of baryon asymmetry depends also on the value adopted for $|C_{23}^L|$.

To reduce the number of parameters, we assume that $C_{23}^L$ and $C_{33}^L$ are real and of equal modulus $|C_{23}^L| = |C_{33}^L|$. As we vary $C_{23}^L$ and $C_{33}^L$ we find essentially the same heavy neutrino spectrum and roughly the same values for $\Delta m^2_2$ and $\Delta m^2_3$, independently of their relative sign. We find that what is dependent on this relative sign is
the amount of CP violation and baryon asymmetry. If $C_{23}^L = C_{33}^L$ (independently of its sign), the baryon asymmetry can be at most of $O(10^{-12})$, but if $C_{23}^L$ and $C_{33}^L$ are of opposite sign, one can get a correct amount of baryon asymmetry.

In conclusion, after some trial and error guesses, we respectively adopt real numbers for $C_{23}^L$ and $C_{33}^L$ for both solutions (1) ($\tan \theta_s < 0$) and (2) ($\tan \theta_s > 0$)

\[
\begin{align*}
(1) & \quad -C_{23}^L = C_{33}^L > 0 \\
(2) & \quad -C_{23}^L = C_{33}^L < 0
\end{align*}
\]

with $|C_{33}^L| << 10^{11} \text{ GeV}$. As it will become clear below, the adopted sign for each of the solutions corresponds to the experimental sign $Y_B > 0$ in some region for the parameters $C_{23}^L, C_{33}^L$. We assume that $Y_{B1} \simeq Y_B$, an hypothesis that will be justified in Section 10.

We will now show how the heavy neutrino and the light neutrino spectra evolve under the conditions (101)-(102). In the next Section we will show how $\epsilon_1$, $\tilde{m}_1$ and $Y_{B1}$ behave.

Of course, our ansatz for $C_{23}^L, C_{33}^L$ is just a guess. We do not intend to make a fit to the overall data, light neutrino spectrum and baryon asymmetry. We just want to see if the description of these data is possible within this scheme of a compact heavy neutrino spectrum and approximate quark-lepton symmetry. Other equations of the type (98)-(99), with complex r.h.s. values for the parameters $C_{23}^L, C_{33}^L$ give also acceptable results, as we will see in Section 9.

### 6.1 Heavy and light neutrino spectra for case (1) $\tan \theta_s < 0$

To perform the calculations we adopt again the values of the pure Cabibbo limit, namely $m_1 = 0.0030 \text{ eV}$, $\tan \theta_{12} = 0.140$, although one could slightly change these values to get a better fit.

In Fig. 1-a the right-handed heavy neutrino spectrum is plotted. In Figures 1-b and 1-c we show respectively the solar and atmospheric quantities $\Delta m_s^2$, $\Delta m_a^2$.
Fig. 1-a. Log-log plot of the right-handed heavy neutrino spectrum (masses in GeV units) as a function of $-C^{L}_{23} = C^{L}_{33} > 0$ in units of $GeV^{-1}$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$. Within the range $-C^{L}_{23} = C^{L}_{33} = 10^6 - 10^7$ $GeV^{-1}$ there is a level crossing. The angular points come from the fact that the curves are obtained from interpolation of a finite number of points. The same applies to the other figures.

Fig. 1-b. $\Delta m^2_s$ in $eV^2$ units as a function of $-C^{L}_{23} = C^{L}_{33} > 0$ in units of $GeV^{-1}$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$, in a log scale for $C^{L}_{33}$. 
Fig. 1-c. $\Delta m^2_a$ in eV$^2$ units as a function of $-C^L_{23} = C^L_{33} > 0$ in units of GeV$^{-1}$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$, in a log scale for $C^L_{33}$.

Let us comment on these figures. The angular points that appear in the figures are an artifact of the representation of the curves, obtained from an interpolation of a finite number of points. Notice that for each point we must perform the singular value decomposition of the matrix $M_R$ in order to compute the quantities necessary to obtain the baryon asymmetry.

The first striking point is that, as we have learned from eqns. \[98\] \[99\], the $N_R$ spectrum (Fig. 1-a) is very compact for $C^L_{33}$ not "too large", $C^L_{33} < 10^7$ GeV$^{-1}$. As explained in the Introduction, there is an expected correlation between the stability of the light neutrino spectrum and the compact heavy right-handed neutrino one. The fine-tuning for the close heavy neutrino masses ensures the stability of the light neutrino ones. For $-C^L_{23} = C^L_{33} > 10^7$ GeV$^{-1}$ the right-handed neutrino spectrum evolves into a hierarchical spectrum. The values obtained for $\Delta m^2_s$ (Fig. 1-b) and $\Delta m^2_a$ (Fig. 1-c) are very stable and consistent with experiment for a wide range of values of $-C^L_{23} = C^L_{33}$, of about eight orders of magnitude.

We observe two other important things in Fig. 1-a: the degeneracy between $N_{R_2}$ and $N_{R_3}$ is lifted, and there is a level crossing around $-C^L_{23} \simeq C^L_{33} = 3 \times 10^6$ GeV$^{-1}$.

An important point to be also underlined is that one of the levels ($N_{R_1}$ before the crossing) remains practically constant in the whole studied range, while the mass of
$N_{R_2}$ decreases. After the crossing we will call $N_{R_1}$ this right-handed neutrino, being the lightest, according to convention \[53\].

As we can see from Figs. 1-b and 1-c, the values obtained for $\Delta m^2_s$ and $\Delta m^2_a$ are in good agreement with the data for a very wide range of the parameters.

For the Majorana phases $\alpha$ and $\beta$, shown in Figs. 1-d and 1-e we find rather constant values (in a logarithmic scale) that are very close but a little smaller than $\frac{\pi}{2}$, as shown in the figures below.

Fig. 1-d. The Majorana phase $\alpha$ as a function of $-C_{23}^L = C_{33}^L > 0$ in units of GeV$^{-1}$, in a log scale for $C_{33}^L$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$. The x-axis is centered at $\pi/2$. 
Fig. 1-e. The Majorana phase $\beta$ as a function of $-C_{23}^L = C_{33}^L > 0$ in units of GeV$^{-1}$, in a log scale for $C_{33}^L$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$. The x-axis is centered at $\pi/2$.

6.2 Heavy and light neutrino spectra for case (2) $\tan \theta_s > 0$

To perform the calculations we adopt again the values obtained in the pure Cabibbo limit, namely $m_1 = 0.0062$ eV, $\tan \theta_{12} = 0.243$.

In Fig. 2-a the right-handed heavy neutrino spectrum is plotted. In Figures 2-b and 2-c we show respectively the solar and atmospheric quantities $\Delta m_s^2$, $\Delta m_a^2$. Figs. 2-d and 2-e display the result for the Majorana phases $\alpha$ and $\beta$. 
Fig. 2-a. Log-log plot of the right-handed heavy neutrino spectrum (masses in GeV units) as a function of $C_{23}^L = -C_{33}^L > 0$ in units of $GeV^{-1}$, for fixed $m_1 = 0.0062 \, eV$ and $\tan \theta_{12} = 0.243$. Within the range $-C_{33}^L = 10^5 - 10^6 \, GeV^{-1}$ there is a level crossing.

Fig. 2-b. $\Delta m_2^2$ in $eV^2$ units as a function of $C_{23}^L = -C_{33}^L > 0$ in units of $GeV^{-1}$, in a log scale for $-C_{33}^L$, for fixed $m_1 = 0.0062 \, eV$ and $\tan \theta_{12} = 0.243$. 
Fig. 2-c. $\Delta m^2_3$ in eV$^2$ units as a function of $C_{23}^L = -C_{33}^L > 0$ in units of GeV$^{-1}$, in a log scale for $-C_{33}^L$, for fixed $m_1 = 0.0062$ eV and tan $\theta_{12} = 0.243$.

As shown in the figures below, in a logarithmic scale, we find for the Majorana phase $\alpha$ a rather constant value that is very close but a little larger than $-\frac{\pi}{2}$ and for $\beta$ a small negative almost constant value.

Fig. 2-d. The Majorana phase $\alpha$ as a function of $C_{23}^L = -C_{33}^L > 0$ in units of GeV$^{-1}$, in a log scale for $-C_{33}^L$, for fixed $m_1 = 0.0062$ eV and tan $\theta_{12} = 0.243$. The x-axis is centered at $-\pi/2$. 

30
Fig. 2-e. The Majorana phase $\beta$ as a function of $C_{23}^L = -C_{33}^L > 0$ in units of GeV$^{-1}$, in a log scale for $-C_{33}^L$, for fixed $m_1 = 0.0062$ eV and $\tan \theta_{12} = 0.243$.

The first striking point in this case is that, as imposed from eqns. (98)(99), the $N_R$ spectrum (Fig. 2-a) has the same features as for the precedent solution, although it is very compact for $-C_{33}^L < 10^6$ GeV$^{-1}$, much more than in case (1). Within the range $C_{23}^L = -C_{33}^L = 10^5 - 10^6$ GeV$^{-1}$ there is also a level crossing, on which we will comment below. For $C_{23}^L = -C_{33}^L > 10^6$ GeV$^{-1}$ the right-handed neutrino spectrum evolves also into a hierarchical spectrum. Secondly, $\Delta m_{a}^2$ (Fig. 2-b) and $\Delta m_{a}^2$ (Fig. 2-c) are very stable for a wide range of values of $C_{23}^L = -C_{33}^L$, of about seven order of magnitude. However, the agreement with experiment is not as good as for solution (1), although it is acceptable within a 3$\sigma$ range. Of course, we could somewhat change the initial conditions $m_1 = 0.0062$ eV, $\tan \theta_{12} = 0.243$ and become closer to the data. This could be done, but we will not do it because our purpose is only a qualitative one within our (fine-tuning) scheme.
7 CP violation and baryon asymmetry in the region approaching the level crossing

Let us turn now to the quantities that are important for Baryogenesis via Leptogenesis. Labelling the lightest heavy right-handed neutrino $N_R_1$, our calculations show that the quantities $-\epsilon_1$, $\tilde{m}_1$ and $Y_{B_1}$ have a strong discontinuity across the level crossing region. We call always $N_R_1$ the lightest heavy neutrino, even after the crossing, according to the convention [53].

We will justify and characterize this term of level crossing, and discuss its implications before this region in Section 10.

To simplify the presentation of the results, we will restrict ourselves to the region before the crossing, where $M_2$ and $M_1$ become relatively close, i.e., to the following regions, slightly different in both cases:

(1) $10^5 \text{ GeV}^{-1} \leq -C_{23}^L = C_{33}^L \leq 10^{6.4} \text{ GeV}^{-1}$

$10^9 \text{ GeV} \leq M_2 - M_1 \leq 8.3 \times 10^9 \text{ GeV}$ (103)

(2) $10^4 \text{ GeV}^{-1} \leq C_{23}^L = -C_{33}^L \leq 10^{5.6} \text{ GeV}^{-1}$

$10^9 \text{ GeV} \leq M_2 - M_1 \leq 2. \times 10^9 \text{ GeV}$ (104)

To avoid the delicate situation related to the quasi-degeneracy of two heavy neutrinos, extensively studied by A. Pilaftsis et al. [25], we need the condition (see also [7])

$$\Gamma_1 << M_2 - M_1 \quad (105)$$

where $\Gamma_1$ is the width of the lightest heavy right-handed neutrino, that has an upper bound qualitatively given by [7]:

$$\Gamma_1 \leq \frac{m_t^2}{16\pi v^2} M_1 \quad (106)$$

Before the level crossing region one gets, from the parameters quoted above ($m_t \simeq m_{D_3} \simeq 100 \text{ GeV}$, $v = 174 \text{ GeV}$ and $M_1 \simeq 5 \times 10^9 \text{ GeV}$):
Therefore, before the level crossing region, taking into account the inequalities (103) (104), we see that in both cases (1) and (2) the condition (105) is satisfied. We are far away from resonant leptogenesis and we do not have to face complications related to quasi-degenerate heavy neutrinos, for which \( M_2 - M_1 \leq \Gamma_1 \).

Let us now show the quantities \(-\epsilon_1, \tilde{m}_1\) and \(Y_{B_1}\) for both solutions within the interesting ranges (103) (104).

### 7.1 Case (1) \( \tan \theta_3 < 0 \)

Fig. 1-d displays the \( CP \) violation parameter \(-\epsilon_1\), Fig. 1-e the washout parameter \(\tilde{m}_1\), and in Fig. 1-f the baryon asymmetry \(Y_{B_1}\) in the one-flavor approximation.

\[
\Gamma_1 \leq 3. \times 10^7 \text{ GeV}
\]
Fig. 1-e. $\tilde{m}_1$ in eV units as a function of $-C_{23}^{L} = C_{33}^{L}$ in units of GeV$^{-1}$, in a log scale for $C_{33}^{L}$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$.

Fig. 1-f. Log-log plot of $Y_{B_1}$ as a function of $-C_{23}^{L} = C_{33}^{L}$ in units of GeV$^{-1}$, for fixed $m_1 = 0.0030$ eV and $\tan \theta_{12} = 0.140$.

We observe that $\epsilon_1$ is negative and becomes large enough in absolute magnitude to give a large positive $Y_{B_1}$ with rather stable values of the parameter $\tilde{m}_1$ that imply strong wash-out in the whole region. Notice that $-\epsilon_1$ as well as $Y_{B_1}$ grow as the mass difference $M_3 - M_2$ slowly grows and the mass difference $M_2 - M_1$ becomes
smaller, a phenomenon already underlined by Akhmedov et al. [7].

The main conclusion that we can draw from Fig. 1-f is that there is no problem to get a baryon asymmetry $Y_{B_1}$ of the right order of magnitude $(Y_B)_{exp} \simeq 9 \times 10^{-11}$.

We must underline that if we did took the opposite sign in (101), we would have obtained the opposite sign for $\epsilon_1$ and therefore also for $Y_{B_1}$. Therefore, our scheme does not predict the sign of $Y_B$ since it depends on the chosen sign of the inhomogeneous terms.

### 7.2 Case (2) $\tan \theta_s > 0$

Fig. 2-d displays the $CP$ violation parameter $-\epsilon_1$, Fig. 2-e the washout parameter $\tilde{m}_1$, and in Fig. 2-f the baryon asymmetry $Y_{B_1}$ in the one-flavor approximation.

```
Fig. 2-d. Log-log plot of $-\epsilon_1$ as a function of $C_{23}^L = -C_{33}^L$ in units of GeV$^{-1}$, for fixed $m_1 = 0.0062$ eV and $\tan \theta_{12} = 0.243$.
```
Fig. 2-e. $\tilde{m}_1$ in eV units as a function of $C_{23}^L = -C_{33}^L$ in units of GeV$^{-1}$, in a log scale for $-C_{33}^L$, for fixed $m_1 = 0.0062$ eV and $\tan \theta_{12} = 0.243$.

We observe that $\epsilon_1$ is negative and becomes large in absolute magnitude to give a rather large positive $Y_{B_1}$ with values of the parameter $\tilde{m}_1$ within the strong wash-out regime.

We must again point out that if we did took the opposite signe of the r.h.s. of
we would have obtained the opposite sign for \( \epsilon_1 \) and therefore also for \( Y_{B_1} \).

The main conclusion that we can draw from Fig. 2-f is that in this case we are somewhat short of having a baryon asymmetry \( Y_{B_1} \) of the right order of magnitude \( (Y_B)_{\text{exp}} \simeq 9 \times 10^{-11} \). However, as pointed out above, one could modify the initial conditions (the values \( m_1 = 0.0062 \) and \( \tan \theta_{12} = 0.243 \)) and get results in better agreement with the data. But it is not our purpose to make a detailed fit for \( \Delta m_s^2 \), \( \Delta m_a^2 \) and \( Y_{B_1} \), we want just to give a qualitative trend.

Let us emphasize again that in the present scheme developed in Sections 6 and 7, due to the reality conditions on \( C_{23}^L \) and \( C_{33}^L \) we have again the interesting limit (97):

\[
\delta_L \to 0 \quad \text{implies} \quad \epsilon_1 \to 0 \quad Y_{B_1} \to 0
\]

\[
\alpha = \beta \to \frac{\pi}{2} \quad \text{(solution (1))} \quad \alpha \to -\frac{\pi}{2}, \quad \beta \to 0 \quad \text{(solution (2))} \quad (108)
\]

8 Results for \( m_{\nu e} \), \( (\beta|\beta)_0 \nu \) and sum of neutrino masses

We give here the predictions for the electron neutrino mass, on which one has limits from tritium \( \beta \) decay:

\[
m_{\nu e} = \cos^2 \theta_s \, |m_1| + \sin^2 \theta_s \, |m_2|
\]

(109)

and for the effective mass relevant for neutrinoless double beta decay \( |< m_{ee}>| \) that writes, within the approximation (33),

\[
|< m_{ee}>| = |\cos^2 \theta_s \, m_1 + \sin^2 \theta_s \, m_2|
\]

(110)

The neutrino masses and their phases for both solutions (84) (89) are very close to those obtained in the region that give an acceptable value for \( Y_B \). Taking thus the values for both solutions, using the notation (34):

1. \( m_1 = 0.0030 \, \text{eV}, \quad m_2 = -0.0095 \, e^{0.0036i} \, \text{eV}, \quad m_3 = -0.0495 \, e^{0.0075i} \, \text{eV} \) (111)
2. \( m_1 = 0.0062 \, \text{eV}, \quad m_2 = -0.0106 \, e^{-0.016i} \, \text{eV}, \quad m_3 = 0.0455 \, e^{0.0078i} \, \text{eV} \) (112)

we obtain, respectively:

1. \( m_{\nu e} \simeq 4.9 \times 10^{-3} \, \text{eV} \) \( |< m_{ee}>| \simeq 5.7 \times 10^{-4} \, \text{eV} \) (113)
\[ m_{\nu e} \simeq 7.5 \times 10^{-3} \, eV \quad | < m_{ee} > | \simeq 1.4 \times 10^{-3} \, eV \quad (114) \]

For both solutions, due to the relative signs among the \( m_i \) (i = 1, 2, 3) (i.e., due to the Majorana phases), there is a strong cancellation between the two terms in (110), a phenomenon already exhibited in [6] in another context. The cancellation is stronger for solution (1).

For the sum of the absolute magnitude of all neutrino masses, we obtain:

\[ \sum_i |m_{\nu_i}| = 0.0620 \, eV \quad (115) \]
\[ \sum_i |m_{\nu_i}| = 0.0623 \, eV \quad (116) \]

One gets very close results for both solutions, that comply with the cosmological bounds [8] and [9] [4].

Let us make a last qualitative remark comparing the different possible future experiments on neutrino masses and stress the importance of cosmological limits.

If one takes \( m_1 \simeq 0 \) one finds, from the data, \( |m_2| \simeq \sqrt{\Delta m^2_s} \simeq 9 \times 10^{-3} \, eV \) and \( |m_3| \simeq \sqrt{\Delta m^2_a + \cos^2 \theta_s \Delta m^2_s} \simeq 5 \times 10^{-2} \, eV \), which correspond to a value for the l.h.s. in eqns. (8)-(9) of the order \( 6 \times 10^{-2} \, eV \), very near the value that we have found and only a factor 3.3 below the bound (9) [4]. So, according to the present scenario, the most promising search for effects of neutrino masses, apart from oscillation experiments, is the analysis of cosmological data, while for beta decay and neutrinoless double beta decay one should need an improvement of more than two orders of magnitude.

### 9 Relaxing the additional reality constraints of the model

We now relax the conditions of the particular model that we have studied quantitatively, namely given by eqs. (98)-(99) with real \( C_{L23} \) and \( C_{L33} \) satisfying (101)-(102), and allow complex numbers for these parameters, keeping however "small" values for the moduli, as stated in (100).
Notice the important point that now we have two new sources of CP violation besides a single independent phase $\delta_L$ (or $\alpha$ or $\beta$), and we recover the situation in which there are three independent phases: $\delta_L$, $\alpha$, and $\beta$. However, as we will see below, in the range of interest for $Y_{B_1}$, the magnitude of the Majorana phases is not very different than in the real case studied in detail in Sections 5, 6 and 7. However, their new contributions have important implications for the baryon asymmetry.

Just to have a feeling of what can happen, we take an extreme case and adopt relations (101), (102) with the condition (100), but taking now $C_{23}^L$ and $C_{33}^L$ purely imaginary. Interestingly, the results are phenomenologically good and show that our general scheme of a compact $N_R$ spectrum is flexible enough.

We do not give the corresponding curves of Sections 6 and 7, and give values for representative points with acceptable phenomenological results.

For case (1), i.e. $\tan \theta_s \simeq -\sqrt{0.4}$ with $m_1 = 0.0030 \text{ eV}$ and $\tan \theta_{12} = 0.140$, taking

$$- C_{23}^L = C_{33}^L = i \ 10^{-5}$$

we find the following results:

$$\Delta m_s^2 = 8.1 \times 10^{-5} \text{ eV}^2 \quad \Delta m_a^2 = 2.4 \times 10^{-3} \text{ eV}^2$$

$$\alpha = \frac{\pi}{2} - 0.0018 \quad \beta = \frac{\pi}{2} - 0.0038$$

$$M_1 = 5.531 \times 10^9 \text{ GeV} \quad M_2 = 1.383 \times 10^{10} \text{ GeV} \quad M_3 = 1.483 \times 10^{10} \text{ GeV}$$

$$\tilde{m}_1 = 0.050 \text{ eV} \quad \epsilon_1 = -2.755 \times 10^{-5} \quad Y_{B_1} = 2.211 \times 10^{-10}$$

while for case (2), i.e. $\tan \theta_s \simeq +\sqrt{0.4}$ with $m_1 = 0.0062 \text{ eV}$ and $\tan \theta_{12} = 0.243$, taking

$$- C_{23}^L = C_{33}^L = -i \ 10^{-3}$$

we find:

$$\Delta m_s^2 = 7.4 \times 10^{-5} \text{ eV}^2 \quad \Delta m_a^2 = 2.0 \times 10^{-3} \text{ eV}^2$$

$$\alpha = -\frac{\pi}{2} + 0.0079 \quad \beta = -0.0039$$
\[ M_1 = 6.847 \times 10^9 \text{ GeV} \quad M_2 = 8.844 \times 10^9 \text{ GeV} \quad M_3 = 8.954 \times 10^9 \text{ GeV} \]

\[ \tilde{m}_1 = 0.170 \text{ eV} \quad \epsilon_1 = -3.622 \times 10^{-5} \quad Y_{B_1} = 7.035 \times 10^{-11} \quad (120) \]

These results are phenomenologically reasonable, and we find a whole region in their neighborhood that gives also good results.

Notice that in the numbers of case (2) we are not far away from saturating the bound \[^{[107]}\], and therefore we are approaching the regime of resonant leptogenesis.

Let us emphasize again that in the case examined here we have two different sources of CP violation: \( \delta_L \) and the Majorana phases \( \alpha, \beta \).

To illustrate how these new contributions to Majorana phases occur, it is useful to recall again how we perform our calculations. Proceeding like in Section 6, using eqns. \[^{[117]}\] and \[^{[119]}\], we compute, from \(^{[38]}^{[39]}\), \( m_2 \) and \( m_3 \) (with the convention \(^{[34]}\)) in terms of the given values for \( m_1 \) and \( \tan \theta_{12} \). Then, \( m_2 \) and \( m_3 \) get by construction new CP-violating contributions to the Majorana phases because, according to \(^{[117]}^{[119]}\), the inhomogeneous terms must be pure imaginary.

Of course, since now we have new sources of CP violation in the Majorana phases, in the limit \( \delta_L \to 0 \) we do not recover the simple limit \[^{[108]}\] that we got for real values of \( C_{L,23} \) and \( C_{L,33} \) or, equivalently, for CP violation in the Majorana phases fixed exclusively from the phase \( \delta_L \).

We had CP violation in Majorana phases that were induced by their calculation for a given \( \delta_L \) in the case of vanishing \( C_{L,23} \) and \( C_{L,33} \) (Subsection 5.2). But, from the imaginary inhomogeneous terms of the present Section, we have now new sources of CP violation in these phases.

These new sources of CP violation in the Majorana phases, although small, are very efficient in producing a baryon asymmetry, as we realize from the results \[^{[118]}\] and \[^{[120]}\].

It can be easily understood that the constraints \(^{[117]}\) and \(^{[119]}\) imply new contributions to the baryon asymmetry. These equations mean that the entries \( A_{L,23}^L = A_{L,32}^L \) and \( A_{L,33}^L \) are purely imaginary. This in turn implies, from \(^{[43]}\), new CP violation contributions to the mass matrix \( M_R \), providing, after its diagonalization, new contributions to \( \epsilon_1 \) and \( Y_{B_1} \). This important phenomenon certainly deserves further investigation for general complex inhomogeneous terms, keeping however a compact \( N_R \) spectrum.
The important conclusion of the calculations of the present Section is that the results presented in Sections 6 and 7 remain much more general than the very particular model that, for the sake of simplicity, was exposed there. Our scheme, although fine-tuned because we look for a compact heavy neutrino spectrum, allows for a wide range of parameters giving good results.

10 Comments on the compact heavy neutrino spectrum and on the level crossing region

We now go back to the case that we have studied in a quantitative detail, namely eqs. (98)-(99) with the conditions (101)-(102).

Before and around the level crossing region we have a rather or very compact heavy neutrino spectrum. For simplicity, we have assumed that the lightest heavy neutrino $N_{R_1}$ decays out-of-equilibrium and gives the main contribution to the important quantities relevant for baryogenesis: $\epsilon$, $\tilde{m}$ and $Y_B$.

In such a fine-tuned situation, this can seem rather artificial. Actually, one should consider the contributions of all three heavy neutrinos, and therefore the contributions of all the CP-violation parameters $\epsilon_1$, $\epsilon_2$, $\epsilon_3$, and the corresponding wash-out factors. Notice that there are studies in the literature that consider all these contributions. See, for example, the paper by E. Bertuzzo et al. [26] and also, in a qualitative way, the work by Akhmedov et al. [7]. However, to take into account the contributions of all three heavy neutrinos can present some subtleties. We have not dared for the moment to roughly add $Y_{B_1}$, $Y_{B_2}$, and $Y_{B_3}$. We simply expect that the possible contributions of all three heavy neutrinos will not strongly affect the results that we have found from $N_{R_1}$. An argument given below supports this hypothesis.

Let us now comment on the crossing region. As pointed out above, there is a level crossing in both cases: (1) $\tan \theta_s < 0$ and (2) $\tan \theta_s > 0$. This happens around $-C_{L_{23}}^L = C_{L_{33}}^L \approx 3 \times 10^6 \text{ GeV}^{-1}$ for solution (1) and $C_{L_{23}}^L = -C_{L_{33}}^L \approx 5 \times 10^5 \text{ GeV}^{-1}$ for solution (2). At some point in this region the heavy neutrinos $N_{R_1}$ and $N_{R_2}$ become degenerate.
But we want to make explicit more precisely what we understand by level crossing. What we mean is that the properties of the $N_{R_1}$ neutrino before the level crossing become (up to signs) those of the $N_{R_2}$ neutrino after the level crossing, and vice-versa, exchanging their effect on the absolute magnitude of the final quantities $\epsilon, \tilde{m}$ and $Y_B$. This can be seen easily by writing the effective Dirac neutrino mass that enters in formulas (51), (54), before and after the crossing region.

To illustrate what happens, we will take as an example solution (1). Similar features appear for solution (2). To be definite, we consider $N_{R_1}$ (the lightest neutrino) and $N_{R_2}$ (the next-to-lightest neutrino) before the crossing region, as we have computed in Section 7. Applying for $N_{R_2}$ naively the formulas (54), (57) and (59) making just the exchange $M_1 \leftrightarrow M_2$, let us give for solution (1) the quantities $\tilde{m}_1, \epsilon_1, Y_{B_1}$ and $\tilde{m}_2, \epsilon_2, Y_{B_2}$ at one point before the crossing region, for example for the value $C^L_{33} = 10^6 \text{ GeV}^{-1}$ and at one point after the crossing, for example for $C^L_{33} = 10^7 \text{ GeV}^{-1}$. Let us recall that the Dirac matrix (87) is completely fixed, but the redefined matrix (51) changes from point to point because it depends on the diagonalization of the matrix $M_R$ by (49).

One finds, before the crossing, for $C^L_{33} = 10^6 \text{ GeV}^{-1}$, the values for the heavy neutrino masses:

\[
M_1 = 5.531 \times 10^9 \text{ GeV} \quad M_2 = 1.017 \times 10^{10} \text{ GeV} \quad M_3 = 2.017 \times 10^{10} \text{ GeV}
\]

and the hermitian matrix that enters in (57) and (54):

\[
\tilde{m}_D^+ \tilde{m}_D \simeq \begin{pmatrix}
0.259 & 18.176 - 0.089i & -0.125 - 25.597i \\
18.176 + 0.089i & 3352.06 & -0.00006 - 4720.59i \\
-0.125 + 25.597i & -0.00006 + 4720.59i & 6647.84
\end{pmatrix} \text{ GeV}^2
\]

and one gets therefore:

\[
\tilde{m}_1 = 0.047 \text{ eV} \quad \epsilon_1 = -2.749 \times 10^{-6} \quad Y_{B_1} = 2.383 \times 10^{-11}
\]

\[
\tilde{m}_2 = 329.586 \text{ eV} \quad \epsilon_2 = -1.425 \times 10^{-10} \quad Y_{B_2} = 4.245 \times 10^{-20}
\]

Notice here one point. The numbers obtained in (123) are very interesting in relation with the calculations done in Section 7 for the region before the level cross-
ing. We have assumed there that $Y_B$ is dominated by the contribution of the lightest neutrino $Y_{B_1}$. We see indeed that, at least within these naive estimate, this is true as far as the consideration of the next-to-lightest neutrino is concerned.

Remember that we have adopted the level ordering convention (53), that applies also after the crossing: $N_{R_1}$ is the lightest neutrino and $N_{R_2}$ the next-to-lightest neutrino.

One finds, after the crossing, for example for $C_{33}^L = 10^7 \, GeV^{-1}$, the heavy neutrino masses:

$$M_1 = 2.011 \times 10^9 \, GeV \quad M_2 = 5.531 \times 10^9 \, GeV \quad M_3 = 1.020 \times 10^{11} \, GeV \ (124)$$

and the hermitian matrix that enters in (57) and (54):

$$\hat{m}_D^+ \hat{m}_D \simeq \begin{pmatrix} 193.27 & -5.937 - 0.020i & -0.00029 + 1376.69i \\ -5.937 + 0.020i & 0.342 & -0.143 - 42.293i \\ -0.00029 - 1376.69i & -0.143 + 42.293i & 9806.55 \end{pmatrix} \, GeV^2 \ (125)$$

and one gets therefore:

$$\tilde{m}_1 = 96.125 \, eV \quad \epsilon_1 = 8.023 \times 10^{-10} \quad Y_{B_1} = -9.981 \times 10^{-19}$$

$$\tilde{m}_2 = 0.062 \, eV \quad \epsilon_2 = 3.694 \times 10^{-6} \quad Y_{B_2} = -2.312 \times 10^{-11} \ (126)$$

The shifts in order of magnitude among the elements of the matrices before and after the crossing, (122) or (125), explain the strong differences (in magnitude and even in sign) of the relevant quantities in these two regions, (123) or (126). We observe a strong discontinuity for the lightest neutrino properties (and for the next-to-lightest ones) that happens going through the crossing region. Up to the sign of $\epsilon$ and therefore of $Y_B$, we see that after the crossing the lightest neutrino has very strong wash-out and very small $|\epsilon_1|$ and therefore $|Y_{B_1}|$, and that the opposite is true for the next-to-lightest heavy neutrino $N_{R_2}$. It is easy to examine this for the parameter $\tilde{m}_i$ ($i = 1, 2$), just by inspection of the matrix elements $(\hat{m}_D^+ \hat{m}_D)_{ii}$ in (122) and (125). For $\epsilon_i$ it is a little more involved, but can be seen also by looking at the squares of the matrix elements of $\hat{m}_D^+ \hat{m}_D$.

Let us now comment on the change of sign of $\epsilon_i$ and $Y_{B_i}$ before and after the level crossing region (123), (126). For solution (1), that we discuss here, the sign of
the inhomogeneous term $-C_{23}^{L} = C_{33}^{L} > 0$ gives $\epsilon_{i} < 0$ and $Y_{B_{i}} > 0$ before the crossing, and $\epsilon_{i} > 0$ and $Y_{B_{i}} < 0$ after the crossing. We have realized that if one changes the sign of (101), i.e. $-C_{23}^{L} = C_{33}^{L} < 0$, then one has the opposite: $\epsilon_{i} > 0$ and $Y_{B_{i}} < 0$ before the crossing, and $\epsilon_{i} < 0$ and $Y_{B_{i}} > 0$ after the crossing. Adopting this latter sign for $C_{23}^{L}, C_{33}^{L}$, nothing essential changes for the heavy neutrino spectrum and for $\Delta m_{s}^{2}$ and $\Delta m_{a}^{2}$. The same considerations apply to solution (2) using (102) and changing its sign.

Our conclusion is that, provided $N_{R_{1}}$ and $N_{R_{2}}$ are close enough in mass, one can have the right order of magnitude and sign for $Y_{B}$ before and after the crossing. This happens only at the price of changing the sign of our single free real parameter $-C_{23}^{L} = C_{33}^{L}$.

An interesting conclusion is that, after the level crossing, the second-to-lightest heavy neutrino $N_{R_{2}}$ dominates. The possibility of next-to-lightest neutrino dominance has been extensively studied recently by S. Antush et al. [27].

11 Open problems within the present approach

There are a number of problems to face and study within the present approach. Let us make an incomplete list:

(i) There is the possibility that more than one heavy right-handed neutrino decays out of equilibrium, contributing to the leptogenesis, a point that, in particular, has been suggested rather clearly in ref. [7]. If we guess a temperature $T \simeq 10^{11}$ GeV below which all heavy neutrinos decay out-of-equilibrium, then not only the lightest $N_{R_{1}}$ decays out-of-equilibrium after the level crossing, but also $N_{R_{2}}$ is in the same situation. On the other hand, the heavy neutrino spectrum being rather compact, the natural thing to do would be to consider the contributions to $Y_{B}$ of all three heavy neutrinos $N_{R_{1}}, N_{R_{2}}$ and $N_{R_{3}}$, i.e. to compute $\epsilon_{1}, \epsilon_{2}$ and $\epsilon_{3}$ and the relevant washout factors.

For the moment we just expect that the consideration of the three neutrinos will not spoil the good features of the calculations of the present paper, that take only
into account the lightest neutrino $N_{R_1}$ before the crossing.

We have given an argument going in this sense in Section 10 where we have seen that, before the level crossing, the contribution of the next-to-lightest neutrino $N_{R_2}$ is negligible compared to the one of the lightest one $N_{R_1}$.

(ii) One should take into account also the level crossing region and therefore the finite width of the right-handed neutrinos, as well as the delicate question of their interference. These problems have been treated in great detail by A. Pilaftsis and collaborators [25] that, to be complete, need to be adopted within our approach.

(iii) The flavor effects, thoroughly studied by A. Abada et al. [28] are also a delicate question to study in this region of compact right-handed neutrino spectrum, and this should also be performed.

(iv) It would be worth to study the more general case for CP violation outlined in Section 9, and make a detailed scan of the results in the case of general complex inhomogeneous terms - or equivalently general light neutrino Majorana phases -, with the constraint of having a compact heavy neutrino spectrum.

(v) It could be that the homogeneous equations (60) correspond to some symmetry, the inhomogeneous terms (that we have introduced to get a large enough CP violation $\epsilon_1$) being a breaking of this symmetry, a possibility that would be interesting.

12 Conclusions

Our demand of a compact $N_R$ spectrum, and of an approximate quark-lepton symmetry implying a hierarchical spectrum for the Dirac neutrino masses with a similar structure between $V^L$ and the CKM mixing matrix, brings to a scenario where the lepton asymmetry comes out naturally, producing the required order of magnitude for the baryon asymmetry $Y_B \sim O(10^{-10})$. We have assumed and justified that $Y_B$ is dominated by the contribution of the lightest neutrino $N_{R_1}$.

In this way, not only one can get a good magnitude for $Y_B$, but as a natural consequence there are also a number of other strong points in this approach.
We get two possible solutions with a normal hierarchical light neutrino mass spectrum and an absolute scale, i.e. the lightest neutrino mass $m_1$ must be non vanishing.

The light neutrino squared mass differences $\Delta m^2_s$ and $\Delta m^2_a$ are very stable and consistent with the data.

There are three CP-violating phases in the whole approach, the phase $\delta_L$ of the $V^L$ unitary matrix, and the light neutrino Majorana phases $\alpha$ and $\beta$. We take $\delta_L$ to be of the order of the Kobayashi-Maskawa phase $\delta_{KM}$.

We have thoroughly studied in a quantitative way a particular case in which all CP violating effects are computed in terms of $\delta_L$, in particular $\epsilon_1$ and $Y_{B_1}$. It is interesting that one can get a baryon asymmetry of the right order of magnitude taking $\delta_L \simeq \delta_{KM}$. Of course, this result is not obtained in the Standard Model, but in a New Physics scheme under particular assumptions: Baryogenesis via Leptogenesis, $SO(10)$ Grand Unification, approximate quark-lepton symmetry and compact heavy $N_R$ spectrum. In the limit $\delta_L \to 0$, one gets indeed $\epsilon_1 \to 0$ and $Y_{B_1} \to 0$.

The $\nu_e$ mass, bounded by tritium $\beta$ decay, is of the order of few times $10^{-3}$ eV.

The sum $\sum_i m_{\nu_i}$ satisfies the cosmological bounds, with a value rather close to the present upper limits.

Let us emphasize that $\delta_L$ induces also small CP violating corrections to the light neutrino Majorana phases, that turn out to be naturally close to $\alpha = \frac{\pi}{2}, \beta = \frac{\pi}{2}$ or 0. The effective neutrino mass, relevant for neutrinoless double beta decay, comes out to be rather small, of the order of $10^{-3}$ eV, because of strong cancellations due to the Majorana phases.

In the region of quasi-degeneracy, the heaviest $N_R$ has a mass of the order $1.5 \times 10^{10}$ GeV, roughly consistent with the expected scale of $B - L$ symmetry breaking, so that $SO(10)$ breaks down to the Pati-Salam group $SU(4) \times SU(2) \times SU(2)$ at the expected natural intermediate scale.

We expose also an example in which the phase of the Dirac neutrino mass matrix $\delta_L$ and the Majorana phases $\alpha, \beta$ are independent, providing an efficient generation of baryon asymmetry.
Acknowledgements

Appendix

In this Appendix we demonstrate the approximate formula (15) for $\Delta m^2_a$:

$$\Delta m^2_a = |m_3|^2 - \cos^2 \theta_s |m_2|^2 - \sin^2 \theta_s |m_1|^2$$  \hspace{1cm} (A.1)

The mass eigenstates read:

$$|\nu_1\rangle = c_s |\nu_e\rangle - \frac{s_s}{\sqrt{2}} |\nu_\mu\rangle + \frac{s_s}{\sqrt{2}} |\nu_\tau\rangle$$
$$|\nu_2\rangle = s_s |\nu_e\rangle + \frac{c_s}{\sqrt{2}} |\nu_\mu\rangle - \frac{c_s}{\sqrt{2}} |\nu_\tau\rangle$$
$$|\nu_3\rangle = \frac{1}{\sqrt{2}} |\nu_\mu\rangle + \frac{1}{\sqrt{2}} |\nu_\tau\rangle$$  \hspace{1cm} (A.2)

and therefore the $\mu$-neutrino state is given, in terms of the mass eigenstates:

$$|\nu_\mu\rangle = - \frac{s_s}{\sqrt{2}} |\nu_1\rangle + \frac{c_s}{\sqrt{2}} |\nu_2\rangle + \frac{1}{\sqrt{2}} |\nu_3\rangle$$  \hspace{1cm} (A.3)

that evolves in time according to:

$$|\nu_\mu(t)\rangle = - \frac{s_s}{\sqrt{2}} e^{(-ip-i\frac{m_2^2}{2p})t} |\nu_1\rangle + \frac{c_s}{\sqrt{2}} e^{(-ip-i\frac{m_2^2}{2p})t} |\nu_2\rangle + \frac{1}{\sqrt{2}} e^{(-ip-i\frac{m_2^2}{2p})t} |\nu_3\rangle$$
$$= e^{(-ip-i\frac{m_2^2}{2p})t} \left[ - \frac{s_s}{\sqrt{2}} e^{i(m_3^2-m_1^2)t} |\nu_1\rangle + \frac{c_s}{\sqrt{2}} e^{i(m_3^2-m_2^2)t} |\nu_2\rangle + \frac{1}{\sqrt{2}} |\nu_3\rangle \right]$$  \hspace{1cm} (A.4)

and, from (A.2), we can write the scalar products:

$$e^{(ip+i\frac{m_2^2}{2p})t} < \nu_e |\nu_\mu(t)\rangle$$
$$= \left[ - \frac{s_s}{\sqrt{2}} e^{i(m_3^2-m_1^2)t} < \nu_e |\nu_1\rangle + \frac{c_s}{\sqrt{2}} e^{i(m_2^2-m_2^2)t} < \nu_e |\nu_2\rangle + \frac{1}{\sqrt{2}} < \nu_e |\nu_3\rangle \right]$$
$$= \frac{s_s c_s}{\sqrt{2}} \left[ - e^{i\frac{m_3^2-m_1^2}{2p}t} + e^{i\frac{m_2^2-m_2^2}{2p}t} \right] = \frac{s_s c_s}{\sqrt{2}} e^{i\frac{m_3^2-m_2^2}{2p}t} \left[ - 1 + e^{i\frac{m_2^2-m_2^2}{2p}t} \right]$$  \hspace{1cm} (A.5)
\[ e^{i(p+\frac{m_2^2}{2p})t} < \nu_{\mu}(t) > \]
\[ = \left[ - \frac{s}{\sqrt{2}} e^{i(\frac{m_2^2-m_1^2}{2p})t} < \nu_{\mu} \nu_{1} > + \frac{c_s}{\sqrt{2}} e^{i(\frac{m_2^3-m_1^2}{2p})t} < \nu_{\mu} \nu_{2} > + \frac{1}{\sqrt{2}} < \nu_{\mu} \nu_{3} > \right] \]
\[ = \frac{1}{2} \left[ s_s^2 e^{i(\frac{m_2^2-m_1^2}{2p})t} + c_s^2 e^{i(\frac{m_3^2-m_1^2}{2p})t} + 1 \right] \quad (A.6) \]

\[ e^{i(p+\frac{m_2^2}{2p})t} < \nu_{\tau}(t) > \]
\[ = \left[ - \frac{s}{\sqrt{2}} e^{i(\frac{m_2^2-m_1^2}{2p})t} < \nu_{\tau} \nu_{1} > + \frac{c_s}{\sqrt{2}} e^{i(\frac{m_2^3-m_1^2}{2p})t} < \nu_{\tau} \nu_{2} > + \frac{1}{\sqrt{2}} < \nu_{\tau} \nu_{3} > \right] \]
\[ = \frac{1}{2} \left[ - s_s^2 e^{i(\frac{m_2^2-m_1^2}{2p})t} - c_s^2 e^{i(\frac{m_3^2-m_1^2}{2p})t} + 1 \right] \quad (A.7) \]

Denoting
\[ \alpha_{ji} = \frac{(m_j^2-m_i^2)t}{2p} \quad (A.8) \]

One obtains, from (A.7) and (A.8) and the relation
\[ \alpha_{31}-\alpha_{32} = \alpha_{21} \quad (A.9) \]

the following probabilities:
\[ | < \nu_{e} | \nu_{\mu}(t) > |^2 = s_s^2 c_s^2 [1 - \cos(\alpha_{21})] \quad (A.10) \]
\[ | < \nu_{\mu} | \nu_{\mu}(t) > |^2 = \frac{1}{4} [s_s^4 + c_s^4 + 1 + 2s_s^2c_s^2 \cos(\alpha_{21}) + 2s_s^2 \cos(\alpha_{31}) + 2c_s^2 \cos(\alpha_{32})] \quad (A.11) \]
\[ | < \nu_{\tau} | \nu_{\mu}(t) > |^2 = \frac{1}{4} [s_s^4 + c_s^4 + 1 + 2s_s^2c_s^2 \cos(\alpha_{21}) - 2s_s^2 \cos(\alpha_{31}) - 2c_s^2 \cos(\alpha_{32})] \quad (A.12) \]

and one obtains, as expected:
\[ | < \nu_{e} | \nu_{\mu}(t) > |^2 + | < \nu_{\mu} | \nu_{\mu}(t) > |^2 + | < \nu_{\tau} | \nu_{\mu}(t) > |^2 = 1 \quad (A.13) \]

Performing an expansion in powers of \( \alpha_{ji} = \frac{(m_j^2-m_i^2)t}{2p} \), one finds
\[ | < \nu_{e} | \nu_{\mu}(t) > |^2 \simeq \frac{s_s^2 c_s^2}{2} \left[ \frac{(m_2^2-m_1^2)t}{2p} \right]^2 \quad (A.14) \]
\[ | < \nu_{\mu} | \nu_{\mu}(t) > |^2 \simeq 1 - \frac{s_s^2 c_s^2}{4} \left[ \frac{(m_2^2-m_1^2)t}{2p} \right]^2 - \frac{s_s^2}{4} \left[ \frac{(m_3^2-m_1^2)t}{2p} \right]^2 - \frac{c_s^2}{4} \left[ \frac{(m_3^2-m_1^2)t}{2p} \right]^2 \quad (A.15) \]
\[ | < \nu_{\tau} | \nu_{\mu}(t) > |^2 \simeq - \frac{s_s^2 c_s^2}{4} \left[ \frac{(m_2^2-m_1^2)t}{2p} \right]^2 + \frac{s_s^2}{4} \left[ \frac{(m_3^2-m_1^2)t}{2p} \right]^2 + \frac{c_s^2}{4} \left[ \frac{(m_3^2-m_1^2)t}{2p} \right]^2 \quad (A.16) \]
with:

\[ | < \nu_e | \nu_\mu(t) > |^2 + | < \nu_\mu | \nu_\mu(t) > |^2 + | < \nu_\tau | \nu_\mu(t) > |^2 \simeq 1 \]  

(A.17)

The last terms in the r.h.s. of (A.16) and (A.17) reads:

\[ \frac{s^2}{4} \left[ \frac{(m_3^2 - m_1^2)t}{2p} \right]^2 + \frac{s^2}{4} \left[ \frac{(m_3^2 - m_2^2)t}{2p} \right]^2 = \frac{1}{4} [s^2 (m_3^2 - m_1^2)^2 + c^2 (m_3^2 - m_2^2)^2] \left( \frac{1}{2p} \right)^2 \]  

(A.18)

and, for \( m_1^2, m_2^2 < m_3^2 \), the bracket in (A.18) becomes

\[ [s^2 (m_3^2 - m_1^2)^2 + c^2 (m_3^2 - m_2^2)^2] \simeq [m_3^2 - (s^2 m_1^2 + c^2 m_2^2)]^2 \]  

(A.19)

and therefore, formulas (A.14)-(A.16) can be approximated by

\[ | < \nu_e | \nu_\mu(t) > |^2 \simeq \frac{s^2 c^2}{2} \left[ \frac{(m_3^2 - m_1^2)t}{2p} \right]^2 \]  

(A.20)

\[ | < \nu_\mu | \nu_\mu(t) > |^2 \simeq 1 - \frac{s^2 c^2}{4} \left[ \frac{(m_3^2 - m_1^2)t}{2p} \right]^2 - \frac{1}{4} \left[ \frac{(m_3^2 - m_2^2)t}{2p} \right]^2 \]  

(A.21)

\[ | < \nu_\tau | \nu_\mu(t) > |^2 \simeq -\frac{s^2 c^2}{4} \left[ \frac{(m_3^2 - m_1^2)t}{2p} \right]^2 + \frac{1}{4} \left[ \frac{(m_3^2 - m_2^2)t}{2p} \right]^2 \]  

(A.22)

that satisfies (A.17) and where

\[ m_2^2 = s^2 m_1^2 + c^2 m_2^2 \]  

(A.23)

Therefore the formula (A.1) or (15) follows.
