Tetrahydrobiopterin Supplementation Improves Endothelial Function But Does Not Alter Aortic Stiffness in Patients With Rheumatoid Arthritis

Kaisa M. Mäki-Petäjä, PhD; Lisa Day, BSc;† Joseph Cheriyan, MA, FRCP; Frances C. Hall, FRCP, DPhil; Andrew J. K. Östör, MBBS, FRACP; Nicholas Shenker, FRCP, PhD; Ian B. Wilkinson, FRCP, DM

Background—Rheumatoid arthritis is a systemic inflammatory condition associated with increased cardiovascular risk that may be due to underlying endothelial dysfunction and subsequent aortic stiffening. We hypothesized that supplementation with tetrahydrobiopterin (BH₄) would recouple endothelial nitric oxide synthase and thus improve endothelial function and consequently reduce aortic stiffness.

Methods and Results—We conducted 2 randomized, double-blinded, placebo-controlled crossover studies examining 2 separate regimens: an acute regimen, with a single dose of BH₄ 400 mg versus placebo (n = 18), and a short-term regimen, composed of a 1-week treatment with BH₄ 400 mg once daily versus placebo (n = 15). Flow-mediated dilatation and aortic pulse wave velocity were studied 4 times, before and after each treatment phase. Acute BH₄ supplementation led to an improvement of flow-mediated dilatation, whereas placebo had no effect (mean±SD of effect difference 2.56±4.79%; P = 0.03). Similarly, 1-week treatment with BH₄ improved endothelial function, but there was no change with placebo (mean±SD of effect difference 3.50±5.05%; P = 0.02). There was no change in aortic pulse wave velocity following acute or short-term BH₄ supplementation or placebo (mean±SD of effect difference: acute 0.09±0.67 m/s, P = 0.6; short-term 0.03±1.46 m/s, P = 0.9).

Conclusion—Both acute and short-term supplementation with oral BH₄ improved endothelial function but not aortic stiffness. This result suggests that BH₄ supplementation may be beneficial for patients with rheumatoid arthritis by improving endothelial dysfunction and potentially reducing risk of cardiovascular disease. There appears to be no causal relationship between endothelial function and aortic stiffness, suggesting that they occur in parallel, although they may share common risk factors such as inflammation. (J Am Heart Assoc. 2016;5:e002762 doi: 10.1161/JAHA.115.002762)

Key Words: arteriosclerosis • endothelial function • inflammation • rheumatoid arthritis • tetrahydrobiopterin

Rheumatoid arthritis (RA) and other chronic inflammatory diseases are associated with increased premature mortality, mostly due to an excess of cardiovascular disease (CVD). A number of underlying mechanisms have been proposed, including endothelial dysfunction. Reduced nitric oxide (NO) bioavailability or endothelial dysfunction is thought to be a key early step in the initiation of atherosclerosis and predicts future CVD-related events in a variety of populations, improving risk classification beyond the Framingham Heart Study scores. We and others have demonstrated that RA patients have endothelial dysfunction, which can be improved with anti-inflammatory therapies. Aortic stiffening, an independent risk factor for CVD, has also been implicated. Several groups have reported increased aortic pulse wave velocity (aPWV) in RA and suggested that this could be a consequence of endothelial dysfunction. Previous studies suggested a link between endothelial function and stiffness of muscular arteries, but whether endothelial function is causally related to aortic stiffness is unknown.

The mechanism of endothelial dysfunction in RA is incompletely understood, but reduced tetrahydrobiopterin (BH₄) availability or stability and increased production of reactive oxygen species have been suggested. Under basal conditions, endothelial nitric oxide synthase (eNOS) is responsible for NO production, but during inflammation, inducible NOS is also expressed in arterial endothelial cells.
Inducible NOS activation impairs vasorelaxation in vitro, at least in part, by limiting availability of BH4 to eNOS,1 and we have demonstrated in vivo that inducible NOS activation in RA is independently related to endothelial function.9 BH4 deficiency is thought to lead to eNOS uncoupling, in which electrons flowing from the reductase domain to the oxygenase domain are diverted to molecular oxygen rather than L-arginine, leading to production of superoxide (O2•−) rather than NO.22 Increased release of myeloperoxidase from activated neutrophils may also play an important role in endothelial dysfunction in RA. Myeloperoxidase catalytically consumes NO and increases the production of reactive oxygen species, subsequently leading to uncoupling of eNOS20 and oxidation of BH4 to inactive BH2.19,23,24 We and others have shown that circulating myeloperoxidase levels are elevated in patients with RA9,25 and independently predict endothelial dysfunction in patients with unstable coronary disease26 and RA.9 Inflammation appears to reduce BH4 bioavailability, which may in part mediate the endothelial dysfunction present in RA; therefore, supplementation with BH4 may be a reasonable therapeutic option to restore normal eNOS function and thus endothelial function in RA. Previous studies have demonstrated that intra-arterial administration of BH4 improves endothelium-dependent dilation in patients with hypercholesterolemia,27 coronary artery disease,28 and type II diabetes.29 Oral BH4 supplementation improves endothelial function in elderly participants,30 in long-term smokers,31 and in patients with hypercholesterolemia32 and hypertension.33 No studies to date, however, have investigated the effects of BH4 in patients with RA. Moreover, it is unclear if improvement of endothelial function would lead to a reduction of aortic stiffness or if other mechanisms are responsible for increased aortic stiffness.

Our aim was to test the hypotheses (1) that oral BH4 supplementation would improve endothelial function in patients with RA and (2) that an improvement of endothelial function would lead to subsequent amelioration of aortic stiffening, providing evidence about the causal relationship between endothelial function and aortic stiffness; BH4 is thought to have little direct effect on inflammation per se.

**Methods**

**Study Population**

Overall, 33 patients with active RA (disease activity score [DAS28] >3.5) who met the 1987 American Rheumatism Association criteria were recruited from the rheumatology clinics at Addenbrooke’s Hospital, Cambridge, United Kingdom. Patients with manifest CVD, untreated hypertension (blood pressure ≥140/90 mm Hg), diabetes, hypercholesterolemia (total cholesterol ≥6.5 mmol/L), or renal disease and current smokers were excluded because these conditions are associated with endothelial dysfunction and arterial stiffening.34 To determine whether baseline endothelial function and aortic stiffness were abnormal in RA patients, 33 age- and sex-matched healthy control participants were randomly selected from our database to compare baseline endothelial function and aortic stiffness. A favorable ethics opinion was obtained from the National Research Ethics Service, and written informed consent was obtained from each participant prior any study procedures.

**Pilot Proof-of-Concept Study**

We conducted a small pilot study in 5 healthy nonsmoking control participants (mean age 27±6 years) to test whether a single dose of BH4 400 mg would improve endothelial function. We found that flow-mediated dilatation (FMD) response increased (from 5.79±1.77% to 11.37±4.05%; P=0.009), and there was a significant change in the baseline diameter (from 3.77±0.52 to 4.10±0.62 mm; P=0.008); however, there was no change in mean arterial pressure (P=0.1) or aPWV (P=0.2). Data are presented as mean±SD, and significance was determined using the paired Student t test. Based on these pilot data, the 400 mg once-daily dose was deemed sufficient for the main study in RA patients and was similar to doses used previously in other conditions.19,33

**Experimental Protocol**

The present study was conducted in a randomized, double-blind, crossover manner. To determine whether acute changes were sustained, patients were allocated to 1 of 2 groups: acute or short-term BH4 supplementation. In the acute study, participants made two 6-hour visits to the vascular laboratory (Figure 1A). On day 1, following the baseline measurement of endothelial function, aortic stiffness, DAS28, and venous blood sampling, participants received a single oral dose of BH4 400 mg or placebo (random assignment). At 3 hours after the administration of BH4 or placebo, the hemodynamic measurements were repeated. A 3-hour time point was chosen based on published pharmacokinetic data.35 One week later, the same protocol was followed, and participants again received either BH4 or placebo.

In the short-term supplementation study, participants made 4 visits, each separated by 1 week. Participants received BH4 400 mg once daily or placebo (random order), each for 1 week, with 1-week washout between treatments (Figure 1B). All hemodynamic measurements were assessed at baseline and at the end of each 7-day treatment period (treatment 1, washout, and treatment 2). Blood was drawn at

DOI: 10.1161/JAHA.115.002762
each time point for the measurement of biochemical markers, and DAS28 was calculated.

BH₄ Tablets

BH₄ was given in a form of sapropterin dihydrochloride (6R-BH₄). 6R-BH₄ is the synthetic form of naturally occurring BH₄ (BioMarin Pharmaceutical Inc) and is approved for treatment of BH₄-responsive phenylketonuria.

Hemodynamic Measurements

All studies were conducted in a quiet, temperature-controlled room. Blood pressure was recorded in the brachial artery using a validated oscillometric technique (HEM-705CP; Omron Corp). Radial artery waveforms were obtained with a high-fidelity micromanometer (SPC-301; Millar Instruments) from the wrist, and a corresponding central waveform was generated using a validated transfer function (Sphygmocor; AtCor Medical). Augmentation index (Alx), a composite measure of wave reflection, mean arterial pressure and heart rate were determined using the integrated software. Aortic and brachial pulse wave velocities were measured, as previously described.⁵⁶

Endothelial function was assessed in the brachial artery using the FMD technique.⁶⁷ Vessel diameter was measured using high-resolution vascular ultrasound (Acuson Aspen; Siemens AG) with a 10.0-MHz linear-array transducer. Brachial artery diameter was measured continuously for 1 minute at baseline and for a further 5 minutes following cuff deflation. The cuff was placed below (distal to) the ultrasound transducer and inflated to 200 mm Hg for 5 minutes. After return to baseline, vessel diameter was again measured continuously for 5 minutes following administration of 25 μg of sublingual glyceryl trinitrate. FMD was defined as the maximum percentage increase in vessel diameter during reactive hyperemia; glyceryl trinitrate–mediated dilatation was defined as the maximum percentage increase in vessel diameter after sublingual glyceryl trinitrate. FMD recordings were analyzed offline by a blinded operator using Cardiovascular Suite Software (Quipu).

Laboratory Measurements and DAS28

Fasting lipid profile, high-sensitivity C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR) were determined using standard methodology at the Biochemistry Laboratory at Addenbrooke’s Hospital.

DAS28 is a validated composite disease activity score. The components of DAS28 include the number of swollen and tender joints from 28 assessed joints, ESR, and patient-assessed visual analog score of overall well-being (scale 0–100). DAS28 was calculated as described previously.⁵⁸

Data Analysis

The primary outcome of the study was the difference in FMD response between BH₄ and placebo treatments. Secondary outcomes were differences in aPWV between treatments, the relationship between changes in aPWV and FMD, and the relationship between CRP and disease activity and change in FMD and aPWV.

Based on our pilot data and published data on BH₄ supplementation, we calculated that a total of 15 patients (per
BH₄ Improves Endothelial Function in RA

The effect of BH₄ supplementation on hemodynamics and vascular function are detailed in Table 2. Following a single dose of BH₄, there was a significant increase in the FMD response, whereas placebo had no effect (+3.57±4.14% versus +1.01±3.12%, between treatments; P=0.03) (Figure 2A). The order in which the treatments were given did not affect the outcome (P=0.8). Baseline diameter of brachial artery or response to sublingual glyceryl trinitrate did not change following the treatment. There were no significant differences between the changes in blood pressure, heart rate, AIx, brachial pulse wave velocity, or aPWV (Figure 2B) following BH₄ or placebo.

Short-Term BH₄ Supplementation

The 1-week treatment with BH₄ led to a significant increase in FMD compared with placebo (+3.69±4.90% versus +0.19±2.51%, between treatments; P=0.02) (Figure 2C). The order in which the treatments were given did not affect the outcome (P=0.7). Again, there was no change in blood pressure or aPWV (Figure 2D).

Seventeen of the 33 RA patients were receiving MTX, a dihydrofolate reductase inhibitor, at the time of the study. Post hoc testing demonstrated that MTX had no impact on the effect of BH₄ on endothelial function (P=0.34) for the drug×visit×MTX interaction. If anything, there was a non-significant trend demonstrating that those on MTX had greater improvement of FMD following BH₄ in comparison to those not on MTX (+4.6±5.0% versus +2.49±3.40%; P=0.18). This was despite no difference in baseline FMD (P=0.9) or brachial artery diameter (P=0.98).

The Effect of BH₄ on Inflammatory Markers and Disease Activity

Following short-term supplementation with BH₄ and placebo, there were no changes in CRP (−0.79±2.6 versus −0.93±3.17 mg/L; P=0.9), ESR (0±7 versus 1±5 mm/h; P=0.6), or DAS28 (0.02±0.46 versus −0.09±0.43; P=0.4) (Table 2).

There was no correlation between the change in FMD and change in aPWV following BH₄ (R=0.27; P=0.20); however, the change in FMD after BH₄ correlated negatively with age (R=−0.44; P=0.01). Baseline aPWV was significantly (P<0.05) correlated with mean arterial pressure (R=0.52), age (R=0.52), CRP (R=0.39), and ESR (R=0.66).

Baseline Comparison With Healthy Controls

The mean age of the healthy control group was 56±11 years. At baseline, RA patients had reduced endothelial function in comparison to control participants (FMD 3.39±2.36% versus 6.16±3.63%; P=0.001). After treatment with BH₄, the FMD response was no longer different between RA patients and controls (6.82±4.83% versus 6.16±3.63%; P=0.5). Baseline aPWV was higher in the RA group compared with controls (7.83±1.80 versus 6.8±1.03 m/s; P=0.006), whereas blood pressure did not differ between the groups (Table 1).

Discussion

The main findings of the present study are that both acute and short-term therapy with BH₄ significantly improves endothelial function, as assessed by vasodilatory response to reactive
hyperemia in patients with active RA, but does not affect blood pressure, AIx, aPWV, or brachial pulse wave velocity. These findings suggest that modulation of endothelial function does not ameliorate arterial stiffness in RA.

The current study demonstrates, for the first time, that oral BH4 supplementation improves endothelial function in patients with RA by 3.5%, restoring it to levels comparable to those of healthy controls. The improvement of FMD was inversely associated with age, suggesting that endothelial dysfunction in younger RA patients may be more reversible than in older patients. FMD has been validated recently as a surrogate marker of future cardiovascular risk. Yeboah et al demonstrated that FMD is a predictor of incident cardiovascular events and that it improves the classification of participants as low, intermediate, and high CVD risk compared with the Framingham risk score in a large population-based cohort. The mean FMD in their whole cohort was 4.4% versus 3.4% in incident cases, suggesting that the improvement seen in our study is likely to have a clinical impact on cardiovascular risk reduction in patients with RA.

Previous studies have demonstrated that intra-arterial administration of BH4 improves endothelium-dependent dilatation in patients with hypercholesterolemia, coronary artery disease, and type II diabetes. Oral BH4 supplementation also improves endothelial function in elderly patients, in long-term smokers, and in patients with hypercholesterolemia and hypertension. Conversely, Cunnington et al showed that although oral BH4 led to an approximate 2.5-fold increase of

plasma BH₄ levels in patients with established coronary artery disease, it had no effect on vascular function or superoxide production because of systemic oxidation of BH₄ to BH₂.¹⁹ The impact of BH₄ on endothelial function has not been assessed previously in RA; however, other interventions (eg, individually designed exercise program) have been shown to improve endothelial function in RA patients.³⁰ Because intracellular BH₄ levels are regulated by de novo synthesis of BH₄ from guanosine triphosphate and through recycling of BH₂ to BH₄ via dihydrofolate reductase,⁴⁰ use of dihydrofolate reductase inhibitors (eg, disease-modifying antirheumatic drugs, MTX) may inhibit the bioavailability of BH₄ in the endothelium. Nevertheless, we found no difference in the effect of BH₄ supplementation on endothelial function between those RA patients on MTX and those not receiving MTX. A trend suggested that those patients on MTX had a greater increase in FMD following BH₄ supplementation, perhaps because of reduced levels of inflammation. Notably, our study was not powered to look at this difference.

We and others have demonstrated that patients with RA have increased aortic stiffening in comparison to healthy participants,¹⁰,¹⁴–¹⁶ and that can be reversed with immunomodulatory therapy.¹⁰,¹²,⁴¹ Our previous studies suggested a link between arterial stiffness and endothelial function,¹⁷,¹⁸ but it is unclear if this relationship is causal or if they occur in parallel in response to common drivers such as increased inflammation. Interestingly, in the present study, neither a single dose nor short-term supplementation with oral BH₄ led to a change in aPWV, brachial pulse wave velocity, AIx, or blood pressure in comparison to placebo. Park et al recently demonstrated in patients with chronic kidney disease that 6R-BH₄ significantly improved AIx; however, there was also a drop in blood pressure, and it appears that the change in AIx was not corrected for change in mean arterial pressure, only for heart rate. Similarly, Porkert et al showed a 15-mm Hg reduction in systolic blood pressure following 8-week treatment with BH₄ 400 mg in hypertensive patients, but this study was not placebo controlled.³³ In healthy older men, BH₄ was shown to reduce carotid artery compliance, but there was a confounding fall in systolic blood pressure.³⁴ In postmenopausal women, however, Moreau et al showed an improvement in carotid artery compliance and FMD response following a single dose of oral BH₄ without change in mean arterial pressure.³⁴

Our study also provided evidence about causality for endothelial function and aortic stiffness. We demonstrated previously that under resting conditions, local NO production modulates distensibility of muscular iliac artery in humans and that exogenous NO increases arterial distensibility; however, data relating to elastic aorta are more controversial.
A recent study by Butlin et al showed that exogenous NO donor sodium nitroprusside does not alter aortic stiffness in vivo in rats. Nevertheless, numerous studies, including ours, have demonstrated a reduction in aortic stiffness, which mirrors the changes in endothelial function, following anti-inflammatory or cholesterol-lowering therapies. The current study clearly demonstrated that improvement of endothelial function, without change in inflammation or lipids, does not lead to reduction of aortic stiffness, strongly suggesting that there is no direct causal link between aortic stiffness and endothelial function. We cannot exclude the possibility that this finding is specific to RA because previous studies have demonstrated changes in aPWV in healthy participants in acute models of induced inflammation.

**Limitations**

We did not assess serum BH4 and BH2 levels in our study; however, numerous studies have demonstrated that supplementation with 6R-BH4 leads to increase in serum BH4 levels. Moreover, we chose the time points based on published findings. Fiege et al demonstrated that the maximal plasma biopterin levels peaked between 1 and 4 hours, with median peak of 3 hours and maximum concentration of 258.7 to 295.0 nmol/L for 10 mg/kg; even 24 hours after administration, 6R-BH4 levels were still 4–5 times the basal values. Moreover, our treatment period of 1-week was very short, and we can neither extrapolate these results to what may be the chronic effects of BH4 supplementation in patients with RA nor predict whether it may have beneficial effects on future cardiovascular events.

**Conclusion**

This study shows for the first time in patients with RA that oral BH4 improves endothelial function as measured by a response to reactive hyperemia. These findings suggest that recoupling of eNOS using cofactor BH4 may provide a rational therapeutic...
approach to prevent CVD in patients with chronic inflammatory diseases. BH$_4$ supplementation did not appear to reduce aortic stiffness, suggesting that endothelial dysfunction is not a pathophysiology behind aortic stiffening in RA and that these conditions may just exist in parallel, both influenced by common risk factors such as inflammation and increased reactive oxygen species production.

**Sources of Funding**

Mäki-Petäjä and Wilkinson were funded by British Heart Foundation. Wilkinson, Cheriyan and Shenker received funding from the Comprehensive Local Research Network and Wilkinson and Cheriyan from the National Institute for Health Research: Cambridge Biomedical Research Centre.
